HENRY MERRYWEATHER, J.P.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

Horticulture in all its Branches.

Founded by W. Robinson in 1871.

EDITED BY F. W. HARVEY.

VOL. LXXVIII. CHRISTMAS, 1914.

LONDON.

Office : 20, TAVISTOCK STREET, COVENT GARDEN, W.C.

Published by "COUNTRY LIFE," Ltd., 20, Tavistock Street, Covent Garden, W.C., and by
GEORGE NEWNES, Ltd., 8-11, Southampton Street, Strand.

THIS VOLUME OF "THE GARDEN"

Is dedicated to

HENRY MERRYWEATHER, J.P.

IT is with considerable pleasure that we dedicate this, the seventy-eighth volume of THE GARDEN, to Mr. Henry Merryweather, who has devoted a long and strenuous life to horticulture. He was born as long ago as January 24, 1839. The son of a gentleman's gardener, he spent his earliest days in private gardens, but at the age of sixteen joined his father in a nursery business which laid the foundation of the now well-known firm of Messrs. H. Merryweather and Sons, Limited., Southwell, Notts. Early in his career, *i.e.*, in the year 1858, about the time the first Rose Show was held in St. James's Hall, he made the acquaintance of the late Dean Hole, who was at that time hon. secretary of the Rose Show, and that commenced a friendship which became very intimate, and was only severed by the death of the venerable Dean. Mr. Merryweather recalls with interest a visit paid by Mr. William Robinson (who founded THE GARDEN), Mr. Noel Humphreys and the late Dean to his nurseries at Southwell, when Mr. Humphreys took away with him a very fine bloom of Rose Maréchal Niel and wrote a diary of the flower in THE GARDEN somewhere about the early sixties. One of the most important events of his life was the introduction of Apple Bramley's Seedling, which was raised in a garden at Southwell. Mr. Merryweather at once realised the value of this splendid culinary Apple, and secured the whole stock. When he first exhibited fruits before the Royal Horticultural Society in 1876, this variety received an award of merit, and subsequently, in 1883, it received the higher recognition of a first-class certificate. The cultivation and improvement of the Rose have always received considerable attention from our friend, and it is to his enterprise that we owe the beautiful Polyantha varieties Jessie and Phyllis. Although horticulture has naturally been his first love, local affairs have received considerable attention, and there is scarcely an organisation in and around Southwell that has not benefited by his presence. Two years ago he was appointed a county magistrate, a position that he fills with credit to himself and the county he represents. In spite of his advancing years, Mr. Merryweather enjoys good health and is as active as many men are at fifty. That he may long be spared to carry on his good work is our earnest wish, in which we feel sure all who have the honour to know him will heartily join.

INDEX.

A.

Abutilon, garden varieties of, 218
 Acacia dealbata, 190; outdoors, 155;
 for a small greenhouse, 89
 Acetylene gas refuse, 111
 Aconite, the Cilician Winter, 53
 Acrostics, 15, 27, 39, 51, 63
 Agaricus comatus, 604
 Alders, some uncommon, 193
 Allotments, cultivation of, 441
 Almonds, planting, for effect, 171
 Alpines from seeds, 187; planting, 187;
 protecting in winter, 31; sowing seeds
 of, 397; the fifty best, 190
 Alstroemerias, transplanting, 89
 Amaranthus Dr. Martin, 356
 Amaryllis Belladonna, habitat of, 552;
 Belladonna speciosa purpurea, 466
 Amygdalus persica rosea flore pleno
 pendula, 220
 Anemones, pruning, 408
 Anemones, increasing, 433
 Annual flowers, work among, 185
 Annuals by the pathside, 8; colour
 effects with, 30, 79, 182; for amateurs'
 gardens, 148; for cutting, 159; for
 rock garden, 410; gardening with, 7;
 half hardy, 170; hardy border of, 214;
 hints on growing, 70; in rock garden,
 170; late sowing of hardy, 540; to
 sow in autumn, 482; six dwarf, 133;
 six good, 460; with other plants, 137
 Anthurium conchiflorum, 196
 Antirrhinum, future of the, 376; Nelrose,
 220; the, 131
 Antirrhinums as bedding plants, 42;
 four good, 231; tall, 142, 166
 Apple, a black, 515; blossoms, 227;
 Harry Pring, 536; jelly, Crab, 516;
 Sandaling Duchess, 248; Winter Ribston,
 623
 Apples, storing, 438; two useful, 438;
 and Pears, pruning, 586; storage of,
 530; their flavour and pedigree, 595
 Aquilegia Stuartii, 377
 Aquilegias in pots, 539
 Arabis aubrietoides Trevor Seedling, 220
 Araucaria imbricata as firewood, 616
 Arches in gardens, 379
 Aristolochia moupinensis, 24
 Asclepias Douglasii, 427
 Ashes, coal, for the garden, 64
 Asparagus, cultivation of, 120; how to
 grow, 208
 Asphodels, the Giant, 465, 472
 Aspidistra, treatment of, 152
 Aspidistras, dividing, 141, 173
 Aster Amellus Arethusa, 486; Amellus
 King George, 466; Cloudy Blue, 512;
 disease, 167, 191, 238; a preventive
 for, 146; viminalis Lovely, 486;
 Purple Prince, 512; the, as a hardy
 annual, 434
 Asters, China, in the woodland, 132
 Aubrietias in the spring, 598
 Aucuba, cultivation and propagation
 of, 197
 Auricula Gordon Douglas, 196; Majestic,
 248
 Auriculas from seed, 221; hints on, 100;
 how to repot, 235; notes on, 3, 67,
 117, 167, 235, 294, 339, 407, 458;
 preparing, for exhibition, 167
 Azaleas, hardy, 586

B.

Bamboos, planting, 237
 Bananas, cultivation of, 478
 Baskets, trug, 486
 Beans, French, awards to, 439
 Bed, a grey and blue, 479
 Bedding, spring, hints on, 503, 534
 Beds and borders for spring flowers, 467
 Bee, leaf-cutting, among Pelargoniums,
 387; and Roses, 398
 Beetroot, lifting and storing, 485
 Begonia Mrs. Harry Barton, 536

Begonias, tuberous, raising from seed, 32;
 winter-flowering, 542
 Belladonna Lilies, 501; in Ireland, 502
 Berberis dulcis, 423
 Blackberry Himalayan Giant, 466
 Bog garden, the, and its formation, 565

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

To Our Readers.—With this issue a new volume of **THE GARDEN** and a new year commence. It is with pleasure that we look back upon the year that has closed and recall the good feeling that continues to exist between Editor and readers. To those who have assisted us in making **THE GARDEN** better known, and those who have so kindly sent us notes and photographs of interest, we tender our best thanks. We fully realise that with this assistance we are enabled to maintain that high standard which is inseparably associated with **THE GARDEN**. In our issue of December 20 we gave a brief summary of the good things that we have in store for readers, and it is with every confidence that we look forward to 1914. The year that has just closed has been a good one for us, and we hope that it has been a good year for our readers. Many have sought advice on gardening difficulties of diverse kinds, and it has been a great pleasure to assist them. We hope many more will write to us during the present year of their gardening successes as well as their failures. We also feel that thanks are due to advertisers who have used our columns during the past year, and hope that readers will continue to support them as they have in the past. Every care is taken to admit advertisements of only reliable firms. To all we wish every happiness and success during the year that has just dawned.

The Preservation of Thatched Roofs.—Those who travel in the country districts must often lament the passing of the thatched roofs that used to be almost universally employed for cottages, barns, stables and other outbuildings. These had the merit of fitting well into the landscape, were cool in summer and warm in winter. Now, galvanised iron, with all its hideousness and other disadvantages, is largely employed. There is a movement on foot to do all that is possible to preserve thatched roofs, and those who are interested in the subject should write to Mr. L. Mark Kenaway, St. Helens, Teignmouth. If an object-lesson of the suitability of thatched roofs for country districts is needed, turn to the illustration on page 9, and imagine the old cottage shown there has a galvanised iron or slate roof.

An Attractive Autumn-Flowering Evergreen Shrub.—Though perhaps more familiar as a pot plant in England south of the Thames and in the West, *Aralia japonica*, or *Aralia Sieboldii* as it is also named, passes through most winters outside uninjured. Flowering usually during October, the large panicles of creamy white flowers form quite a distinct and attractive feature at this season. Their beauty is also considerably enhanced by the large, fan-shaped, rich green leaves. It is quite a good evergreen for the town and suburban garden, so that when plants growing in pots become too large for the living-room and small greenhouse,

or lose their bottom leaves, it is worth while planting them outside. *Aralia japonica* is a very popular plant in the florists' shops, being commonly, though erroneously, sold as the Castor Oil Plant, a name which really belongs to *Ricinus communis*. It may be readily raised from seeds, which will be found listed in most seed catalogues.

An Ornamental Fruiting Thorn.—Apart from their flowers, the majority of the Thorns are very ornamental when in fruit. *Cratægus Carrièrei* is one of the best. Conspicuous as it is when in flower, it is more so when it is bearing its large, orange-coloured fruits. At the present time it is quite an object of beauty, and this is all the more noticeable as it is practically the only one left, the others having been stripped by birds. Probably the fruits of this one are not so palatable to them.

The Value of Beech Hedges.—Hedges are used for many purposes, and there are a host of plants suitable for making them, according to their situation; but few subjects are more effective at the present time than a well-grown Beech hedge. In a dwarf state the leaves of Beech remain on, and for that reason they are valuable as a protection for plants from cold winds, as well as giving a rustic and somewhat warm appearance by their brown, dry leaves during the dark dull days of winter.

Retarding Fruit Blossom.—In order to retard the flowering period of such trees as Nectarines, Peaches and Apricots, it is a good method to withdraw the nails and shreds, or ties, so as to liberate the branchlets from the influence of the brick walls, which conserve and radiate the warmth of the sun's rays. By exercise of timely attention in the matter, it increases the prospects of securing crops of fruits from unprotected trees upon walls. The trees can be nailed or tied up again a week or two before the flowers begin to open. If the old nails and shreds which are removed are subjected to fire, and placed in a sieve when cool, the nails can be easily separated from the ashes and can be used again.

Marram Grass for Paper-Making.—The current issue of the *Kew Bulletin* contains some interesting particulars of experiments which have been conducted in this country in the making of paper from Marram Grass, *Ammophila arundinacea*. This plant grows on most of the sandy shores of the British coast, and, as good paper has been made from its fibre, it would appear to be well worth the attention of those who have such land under their control. It is frequently used for binding sand, and in New South Wales, where it was introduced in 1883, sheep are regularly fed on it, so that there is no doubt it would stand repeated cutting of its leaves. In the Port Fairy district of Victoria, Australia, miles of sand dunes have been reclaimed by planting Marram Grass, whence it has been sent to many other Colonies for the same purpose.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Winter Jasmine.—This is just now very beautiful in flower. Its long sprays of soft yellow give it a peculiar charm of its own, and really ought to be more generally cultivated. It is not particular about the position it occupies, but will thrive in almost any situation, and is always welcome at this season of the year. I know of a large bush growing on a lawn in Stonehouse, and to my knowledge it has been there thirty years. It makes a good show of its pretty yellow flowers during the winter months, and is so useful for room decoration.—L. W. DRIVER, *Stonehouse*.

A Little-Known Ranunculus.—I am sending you three photographs which may be of interest to you. No. 1 is *Ranunculus Matthewsii*. This is not so good as usual, as, owing to the very mild winter, it has been in flower for over three months, and has now a number of blooms still out, the individual flowers being 3 inches in diameter. No. 2 is *Ourisia macrocarpa*. Dr. Cockayne thinks this a new species. It is not so strong a grower as the type, but does well in cultivation. No. 3, *Aciphylla Colensoi*, is rapidly disappearing owing to rabbits and fire.—W. WILLCOX, *Queens-town, New Zealand*.

A Pretty Tea Rose.—I refer to the fairly recent variety *Rosomane Narcisse Thomas*. We have grown it for two years, and can vouch for it being a good grower and free bloomer. The beauty of its foliage is very noticeable, having more of that attractive bronze tinge in the early stage of growth than the majority of Roses, and passing finally to a deep glaucous green. Perhaps the colour of the flowers may be described as scarlet-crimson with a suffusion of apricot; at least, this will do for its bud and half-developed stage, when it is really at its best, for, like all other varieties possessing such beautiful shades of colouring, it loses some of its richness on opening.—C. T., *Highgate*.

Mildew on Roses.—In reply to Mr. Charles P. Serjeantson in your issue for December 27, page 642, in which he asks for the experience of others who have given Messrs. Gleeson's Serum a trial, I can fully bear out every word Mr. E. Molyneux said in its favour. I have used it rather extensively during the past season, with the most remarkable results. Early in August the majority of our Roses became badly infested, one or two varieties which are prone to it especially so. We applied Serum according to directions, and it acted like magic. Some shoots which were perfectly white were thoroughly cleansed, and in a few days the foliage became quite natural. We gave two more slight applications at intervals of about ten days. The bushes became most healthy, and produced a wealth of bloom, owing partly to the mildness of the weather, right up to the middle of December, such as I have never experienced before during the thirty years that I have lived at Aldenham. The most satisfactory point about the Serum is that it leaves no sediment and appears to be quite harmless to any flowers or foliage. I have also used it with the same good

results on winter Cucumbers, Tomatoes and other plants affected. When more widely known, I predict a great future for this preparation.—E. BECKETT, V.M.H., *Elstree*.

Plants Flowering on Christmas Day.—I think the following list of flowers in bloom, made in my garden on Christmas Day, may be of interest as showing the extraordinary mildness of the season: White Marguerite, Chrysanthemum, Wallflower, Violet, Passion Flower, yellow Jasmine, Marigold, Geranium, Feverfew, coloured Primrose, white Primrose, yellow Primrose, Cornflower, purple-tipped Clary, Love-in-a-Mist, Snapdragon, Godetia, Silene, Brompton Stock, Tobacco Plant, Nasturtium, Lobelia, Aubrietia, yellow Alyssum, Campanula attica, Daisy, Delphinium and six varieties of Roses. The garden is situated very

RANUNCULUS MATTHEWSII IN A NEW ZEALAND ROCK GARDEN.

high and is a good deal wind-blown. Has it been known before that Aubrietia and Alyssum are blooming at the same time as Lobelia and Geraniums? In the woods and fields of the Isle of Wight I have also seen in the last day or two Primroses, blue Dog Violets, Ragwort in full bloom, Dandelion, Daisies, Speedwell, Camomile Daisy, Cow Parsley, Scabious, Groundsel, white Violet and pink Campion, and the catkins are out on the Nut trees.—K. H., *Isle of Wight*.

Pruning Gooseberry and Currant Bushes. In "Notes of the Week," issue December 6, the reference to the pruning of Gooseberry and Currant bushes will be welcomed by many readers. In country, and even many suburban districts birds are very destructive. Undoubtedly, autumn pruning (as relating to pruning and its effect on the bushes) is

more beneficial than that done in the spring. At one time I grew about an acre of these bush fruits, and tried pruning at different dates. One year I pruned a Gooseberry bush very early in the autumn. There being so many others for the birds—in a bird district—to tackle, this one bush was left untouched. In spring, this early-pruned bush commenced to grow nearly a week earlier than the spring-pruned ones, and, moreover, kept ahead and bore a heavier crop of finer berries. I have never tried the effect of syringing with petroleum; but if birds can be kept at bay by its application, then the result will be of much advantage to fruit cultivators.—G. G.

Secateurs v. Knife.—Mr. Duncan Pearson's note on page 631, issue December 20, 1913, is timely, but allow me to say that Auberts' secateurs are the best, because both blades cut clean and are so powerful that a shoot of any size that the opening will allow can be readily cut, almost as clean as with a knife. The newest make have one handle turned back to form the spring which opens the knives, and cannot clog with chips or soil. Auberts also make what they call French Vine loppers in two sizes, with handles about twenty inches long. These are very powerful, and require both hands to use; but they cut even old wood like cheese. Both of these are kept by seedsmen, and are far preferable to the old sorts with wooden handles, which have only one cutting edge, and thus bruise the wood below the cut on one side.—GEORGE BUNYARD, *Maidstone*.

Plants Flowering Late.—The following plants were in bloom at Bryn Oerog, near Llangollen, on December 14, 1913: *Rudbeckia Newmanii*, Wallflowers, Pentstemons, Antirrhinums, *Salvia dulcis*, *Laurustinus*, *Aubrietia Lloyd Edwards*, *Helleborus foetidus*, *H. niger altifolius*, Ivy-leaved Geraniums, Pink Cyclops, *Erigeron philadelphicus*, *E. mucronatus*, *Violas*, double Furze, *Potentilla splendissima*, Primroses (various), double white Clematis, *Menziesia polifolia alba*, *Lithospermum prostratum*, *Oxalis arborea*, *Arabis albida*, yellow Polyanthus, *Galanthus cilicicus*, *Eomecon chionantha*, *Lobelia fulgens*, hybrid Heucheras, white Fumitory, *Erinus alpinus*, *Linum arboreum*, *Delphinium Queen of Delphiniums*, *Chrysanthemum maximum* Mrs. C. Lowthian Bell, *Heuchera Edge Hybrid*, *Verbena Miss Willmott*, *Hypericum moserianum*, *Gaillardias*, *Scabiosa caucasica*, *Lupinus subcarnosus*, *Achillea Single White*, *Campanula persicifolia* (white, also the blue),

German Scabious (various), *Viola cornuta*, *Anemone coronaria* (many), Rose Dorothy Perkins, Hybrid Tea and China Roses, common Honeysuckle, *Cyclamen cilicicum*, *Cheiranthus Allionii*, *Arabis aubrietoides*, *Mesembryanthemum* (rose coloured), *Asteriscus maritimus*, double yellow Alyssum, *Alyssum citrinum*, Sweet Alyssum (white, annual), *Campanula garganica*, *C. g. hirsuta*, *C. muralis*, *C. m. major*, *Iberis gibraltarica*, *Convolvulus Cneorum*, *Potentilla willmottiana*, *Polygonum vacciniifolium*, *Polygala Chamæbuxus*, *P. C. purpureus*, *Helianthemum* Mrs. C. W. Earle (double red), a salmon red *Pulmonaria*, *Myosotis dissitiflora*, Red Valerian, Alpine Phlox Vivid, *Auricula Yellow Beauty*, *Iberis sempervirens*, *Jasminum nudiflorum*, *Schizostylis coccinea* and many others.—E. J. LLOYD EDWARDS.

Corydalis thalictrifolia.—This charming plant, so well portrayed in your issue of December 13, page 621, is of more than passing interest. Though introduced in 1900 by Messrs. J. Veitch and Sons from China through their collector Mr. E. H. Wilson, it is not so generally grown as it deserves to be. It makes a pretty plant for the rock garden, but it can only be regarded as half-hardy. Its elegant foliage and pale yellow flowers make it a charming subject for edging groups of plants in the cool greenhouse; it also has the merit of remaining in good condition for a long time. It is not so generally known that it is an excellent subject for house furnishing, as it keeps in a good state for weeks, even under the adverse conditions that obtain in London. Its cultivation presents no difficulty, as it is easily raised from seeds sown in a cold frame or greenhouse, while at all stages of its growth it requires quite cool treatment. It should prove a very useful subject for the amateur with a small greenhouse.—IAN.

The Horseshoe Fern.—In your answer to "Mrs. J. B. L.," page 628, December 13, you state that this Fern is unknown to you. For the benefit of your correspondent allow me to say that it is a name sometimes applied to the New Zealand *Trichomanes reniforme*, which is, however, more often known as the Kidney Fern. Unlike the other members of the genus to which it belongs, the fronds are quite simple, that is, not divided in any way. They are from 2 inches to 4 inches broad, of a transparent nature, and supported on stems from 4 inches to 6 inches in height. The individual fronds are kidney-shaped, with a deep notch at the base. This *Trichomanes* belongs to the class known as Filmy Ferns, and thrives best in a close, moisture-laden atmosphere, such as under a hand-light or in a close case in a fernery kept at a greenhouse temperature, while it may also be grown in a Wardian case in a room. Shade from sunshine in any way is very necessary. It thrives best in a mixture of fibrous peat and soft sandstone with a little sand, and needs a liberal quantity of water.—H. P.

Chrysanthemum Elegance.—Re "Caledonia's" note on single-flowered *Chrysanthemum Elegance* in your issue of November 29, page 595, I may say I grew this variety some years ago, but discarded it, as it was too late in flowering for this district. In notes on early-flowering *Chrysanthemums* in a Scottish contemporary in November, 1905, I stated that *Elegance* was just showing colour at the time of writing (October 18). Our Scottish climate is, like its coast-line, variable. October varieties suit the seaboard, but in the Midlands we want varieties that will flower from the end of August onwards. Our season is a short one, blooms and buds being sometimes frozen past recovery by the first week in October. This season is an exception, a full harvest being vouchsafed. During the past twenty years' residence here I cannot remember a season so immune from frost. Only one morning was there sufficient (7°) to blacken Dahlias. In the same notes *Pink Beauty* is classed as too late and *Miss Rose* too small, both discarded. I remember the stubby growth of *Elegance*. I would get cuttings either from Messrs. W. Wells and Co. or Messrs. H. J. Jones, probably the latter.—S. H., *Stirling, N.B.*

FORTHCOMING EVENTS.

January 13.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster.

January 22.—Gardeners' Royal Benevolent Institution's Annual General Meeting at Simpson's, Strand, London.

WHICH IS THE GUERNSEY LILY?

WE have just read the article on the above plant by Mr. Jacob on page 619 of your issue for December 13, 1913, and can only say, after reading this and many articles that have appeared in the horticultural Press of late, how regrettable it is that such a useful and interesting family—and one that is so easily accommodated and which gives such ample return in pleasure for any trouble taken in growing—should be in such a terrible muddle as regards nomenclature. Unfortunately, *Nerines* have never been popular flowers. They are admired when in bloom, but have never been greatly sought after, as have the Daffodil and Rose, and this want of popularity is the root of the trouble that is now existing over their many names. If you buy a Daffodil and it is wrongly named, though you do not know it yourself, the chances are that your neighbour, when looking over the garden wall, can correct the label and is proud of the fact. The same may happen with a wrongly named Rose and many other plants and flowers, because they are popular and well known to every owner of a garden, whether large or small; but, unfortunately, with the *Nerine*, though a plant of quite as many parts, it is altogether different.

Nerine sarniensis, the true Guernsey Lily, bears umbels of rosy carmine blooms, having neither orange nor scarlet nor salmon blood in them. They glisten somewhat in the sunlight, but not nearly as much as many others of the family. This plant until a few years ago was quite at home in the island of Guernsey, and was to be met with very frequently in the larger as well as in the cottage garden; but, alas! it is now very scarce, and becoming more so as each year rolls by. It is, perhaps, more than most *Nerines* very opposed to moving, neither does it like confinement, and on this account is not such a good pot plant as are many of the others.

One of the reasons, we believe, for so many totally distinct *Nerines* being named alike is that they are so awfully slow to propagate by offsets, but quick by seed, and a very large number of people, having a great liking for seeds and their raising, and having been enraptured with someone else's *Nerines*, have asked for seed of them, and when the seedlings have flowered they are named as the donor has named his.

Mr. Jacob says his blooms of *N. sarniensis*—and we believe he has the true variety, judging from the description he gives of his flowers; we mean the blooms from the bulbs bought in Guernsey—were called *rosea*. This surely means that it is a variety (sport or hybrid) of *sarniensis*; but we think that such a name as *rosea* being applied to a variety of a rosy carmine plant is very misleading, and only tends to confuse growers, as the difference between a rosy carmine, under certain conditions of growth, at certain seasons and by certain lights, and a *rosea* is not sufficiently distinct, and suggests, again, that it is a seedling or sport, which for some better name the owner has called *rosea*, not knowing what it is from or what its parent was like.

We think, now that the *Nerine* is being taken up in earnest, it is quite time that some classification was started.

Guernsey.

SARNIENSIS.

SEASONABLE NOTES ON AURICULAS.

AT one time the Auricula was largely cultivated, especially by amateurs, but for some reason it ceased to be popular. Now, however, there are unmistakable signs that it is once more in the ascendant.

For the Outdoor Garden.—The Auricula is an ideal subject for the amateur, who may either grow it in the border or in unheated frames. Two varieties, viz., Celtic King and the yellow Queen Alexandra, are splendid for the open border, the latter producing a fine effect when planted in small groups; but it is much improved by frame culture.

As a Frame Plant.—I fully recognise the value of the Auricula for the border and cottagers' window-boxes, but to secure the finest results a cold house or frame is necessary, especially if we wish to exhibit or cultivate what is known as the show section, which embraces the selfs, green-edged, grey-eyed and white-edged.

The Position of the Frame should, if possible, be on the south side of a building during the dull period of the year, say, from October to March; but in summer a north aspect is preferable. In spite of some old writers, there are few, if any, secrets regarding the cultivation of these beautiful flowers. The principal factors are a sweet rooting medium, cleanliness, and careful watering at all times.

Plants During January.—For the last two months little attention has been needed beyond giving plenty of ventilation and keeping the plants as dry as possible overhead and at the root without their becoming dust dry. Similar treatment will be required during the month of January; but if the weather remains open and tolerably dry, a little more water may be given at the roots, as the plants will now be preparing to awaken from their resting period. Woolly aphis and green fly are the chief insect pests, and directly these are seen the frame ought to be vaporised with XL All. The latter pest is easily destroyed, but the former is more difficult to dispose of. A little methylated spirit or tobacco powder will kill all that congregate around the stems of the plants and on the surface of the soil if the fumigation does not prove effectual.

Roots Decaying.—It sometimes happens that a plant (particularly through the winter months) looks sickly, and if we examine that example we shall find that the tap-root has begun to decay at the bottom and the decay is gradually working up through the plant. As a rule, it can be easily lifted out of the soil, when the rotten portion must be cut away, and, after some powdered charcoal or lime has been placed over the wound, the plant should be put into a small pot, where it will soon recover if carefully watered.

Some Good Varieties.—Most firms offer Auriculas fairly cheap if purchased by the dozen and the selection is left to them; but for the uninitiated I append a list of useful and easily grown sorts. Alpine—Argus, Bluebell, Claude Halcro, Duke of York, Firefly, Ganymede, General Buller, Martin Smith, Mrs. H. Turner, Rosy Morn, Teviotdale and Uranie. Show—Henry Wilson, Love Bird, Mrs. Henwood, Colonel Champneys, William Brockbank, Acme, Heather Bell, Rachel, Favourite, Mikado, Mrs. Phillips and Ruby. T. W. BRISCOM.

PHLOXES AND PENTSTEMONS FOR LARGE AND SMALL GARDENS.

TOO often those who only have small gardens sit down and bemoan the fact, and envy those who have at their disposal broad acres of open land and woodland glades. It is true that the latter can attempt gardening on a more lavish and comprehensive scale than those who have a modest quarter of an acre or even less. Yet in such a limited space many excellent results and a vast amount of pleasure can be obtained, provided the owner is enthusiastic enough and uses common sense in planning and planting. One of the most interesting and charming gardens of small dimensions that we have seen is at Ditchett, Romford, the residence of Dr. S. Wright, a well-known and highly respected resident, and one who is particularly keen on gardening.

Although the garden at Ditchett is less than a quarter of an acre in size, it is filled from spring until winter with interesting, beautiful, and often rare flowers. Roses, Delphiniums, Phloxes and Pentstemons are his favourites, and the last two named are as fine as, or even a little better than, any we have ever seen. The bed shown in one of the illustrations was so good and so full of flowers that the camera could not penetrate to the interior; but enough are shown to indicate how well these Pentstemons were doing. Phloxes, as will be seen in another illustration, were also wonderfully good; and with a view to assisting those of our readers who may be similarly situated, Dr. Wright has kindly given his methods of cultivation, which are as follow:

"The Phloxes are raised annually from cuttings taken in the spring. As soon as the old plants have growths 4 inches long they are thinned down to four, and these tied out on short sticks. The 'thinings' are used as cuttings and inserted in boxes of light sandy soil, and, as soon as they are rooted, planted out in a nursery bed. They give good heads of bloom late in the autumn, when the parent plants are over; they are then planted in a prepared bed and left for two years. About sixty varieties are grown; the best of which are Dr. Konigshofer, Etna, Baron von Dedem, G. A. Strohle, Tapis Blanc, Gruppen Königin, Maja, Selma, America, Le Mahdi, Mme. Paul Dutrie, Embracement and Goliath.

The Pentstemons are all home-raised except one variety (George Home). A bed of seedlings was grown annually for several years and cuttings taken from any that appeared worth propagating. Cuttings are taken as soon as they can be obtained

after the end of August, put in boxes of sandy soil 6 inches deep, and, as soon as a little growth shows, the tops are pinched out, so that one gets strong plants with three or five growths to plant out in spring. They have been grown on the same site for six years (though one does not recommend this).

The bed is manured with farmyard manure in November, bastard-trenched, and left rough until about a fortnight before replanting. The pick of the collection is a seedling, edged and flushed with pink (in the way of *Rosa alba*), but the ground colour is a pronounced cream—almost yellow when first opening—an immense flower, tall and strong in growth, every flower on the spike opening perfectly."

A BORDER OF MIXED FLOWERS IN DR. S. WRIGHT'S GARDEN AT ROMFORD.

Many of the Delphiniums in this garden are seedlings of Dr. Wright's own raising, and some that we saw earlier in the year were very charming indeed. They included a wide range of colours; the individual flowers were large and well placed on tall, massive stems that were a sure indication of good cultivation. Other fine herbaceous plants, many of them raised from seed, are Oriental Poppies, including some unique seedlings from Jenny Mawson; Geum Mrs. Bradshaw, varieties of *Chrysanthemum maximum*, *Achillea Ptarmica* The Pearl, *Heleniums*, *Statice latifolia*, *Nepeta Mussinii*, *Rudbeckia speciosa* and perennial Sunflowers.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES.

(Continued from Vol. LXXVII., page 648.)

Mrs. Leonard Peirie (Alex. Dickson and Sons, 1910).—I am inclined to think this is one of the best of the decorative Roses of that somewhat indefinite colour yellow, fading to primrose cream and white. In the bud it is a good distinct colour, flushed on the outside of the petal with carmine. In the fully open flower this becomes pale sulphur to pale cream. The flowers are of good shape, freely produced, of delightful fragrance, and the plant is an excellent grower and makes an ideal bedding plant.

Mrs. Sam Ross (Hugh Dickson, 1912).—I referred to this Rose when writing of the exhibition varieties, but it is too good a garden Rose to leave out here. It is a deeper colour than the last named, being deep chamois yellow, shading to light primrose, with a touch of buff on the outside of the petals which gives it the deeper colour referred to. Its large, full and well-shaped flowers are very freely produced, and it is quite a good grower; fragrant.

Mrs. Wakefield Christie Miller (S. McGredy and Son, 1909).—This makes a fine splash of colour as seen from a distance, but the flower is more like a large *Pæony* than a Rose. Still, some people greatly admire it. It is very free-flowering, especially in the autumn, and for an Irish-raised Rose particularly free from mildew.

My Maryland (J. Cook, 1909).—An American-raised variety, and very good under glass, I am told. It has not been bad out of doors here with me, but it is not as good as Mme. Segond Weber, which it resembles, and I do not think we want them both. There was an excellent table at the autumn show of the National Rose Society of this Rose (from under glass) that created a good deal of curiosity as to its correct name, and the judges must have found it difficult to decide between it and Melody. Eventually My Maryland was placed second; but as there exhibited, namely, from under glass, there was no denying its beauty.

Old Gold (S. McGredy and Son, 1913).—This is undoubtedly one of the freest-flowering Roses we have. My small bed of five plants came into flower in May, and I have flowers of it in front of me as I write in mid-December. I cannot recall passing that bed without seeing some flowers on it during the whole period. The habit of the plant, apparently, is to continually send up fresh shoots, the first flowers of which are out before the last of the previous shoot are over, so that we have at last the true Hybrid Perpetual, although it may also be, and is, a Hybrid Tea. In its early stages the bud might almost be taken for Irish Elegance—slightly deeper in shade, perhaps—and

A FULL BED OF WELL-GROWN PENTSTEMONS.

it is in this stage the flower should be cut and not allowed to develop on the plant, as it lasts a long time in water. If left on the plant, the colour goes quickly, and the main beauty of the flower is lost. The dark bronze foliage sets off the lovely buds and is a fine contrast. An excellent grower. The flowers are held erect and on strong footstalks that require no artificial aids or wiring to keep them erect when cut. It is not a single, but has very few petals (after the style of Mrs. Alfred Tate). Quite mildew-proof here, fragrant, and strongly recommended.

Ophelia (William Paul and Son, 1912).—I first saw this Rose at the Chelsea International Exhibition of 1912, and was much taken with its refined shape and appearance. It is, in fact, almost Tea-like in both. Colour, pale flesh, flushed rose. It is not a large flower, but a very beautiful one. Not unlike Margaret, but paler.

Queen Mary (Alex. Dickson and Sons, 1913).—To my way of thinking this is *the* Rose of the year, and not only of the year; I am not sure it would not get my vote as the most beautiful of all Roses. Only those who have grown it can know how very beautiful it is. The large tripod of flowers that were put up when it secured the gold medal were not really typical; they were, in fact, grown under glass, and lacked the delicate refinement of the more naturally-grown blooms. In fact, I saw them commented on as not unlike Juliet! I myself cannot see any resemblance. I once heard a discussion between two well-known rosarians as to the respective merits of Mildred Grant and, I think, White Maman Cochet. The Tea man closed the discussion by calling

Mildred Grant "a bold, brazen-faced hussy." That is perhaps an unfair description of Juliet—but! The only thing in common between the two Roses is that they are both bicolors; there the resemblance ends. Queen Mary opens up a new vista for us. An artist has been at work with an entirely new method of applying his colours. There is nothing quite like it in the Rose world. One has seen fleeting glimpses of it perhaps in an unusually highly coloured flower here or a chance bloom there, but

For as the grower becomes more expert his ambition increases, and often he is tempted to try varieties with which the chances of success are small. But a town garden, intelligently looked after, gives better results than one in the country in which Roses are left to grow themselves; and, given a moderately open position, the number of sorts that can be made to thrive in the neighbourhood of large cities is limited only by the space at the gardener's disposal and willingness to plant.

here it is fixed. If the beauty of any Rose is enhanced by the dew on its petals, surely this is the one. I am not going to pretend to describe its colour. Those who want to know what it is like must grow it. [A coloured plate of it appeared in the issue for October 11.—ED.] I have turned up the raisers' description, but even their well-known eloquence for once has failed them. One reads that it created a sensation among all those who saw its first flowers, so much so that all kinds of schemes as to its future were formulated. Can one doubt that the right solution was arrived at when it was decided to name it Queen Mary?

Southampton. H. E. MOLYNEUX.

(To be continued.)

ROSE-GROWING IN TOWN GARDENS.

THE average town gardener is apt to become a little wearied by the repetition of some dozen names, which constitute the official list of town Roses.

Certainly he never does limit his selection solely to these varieties, and taste alone determines his final choice.

BORDERS OF HERBACEOUS PHLOXES IN A SMALL GARDEN.

The Best Varieties to Plant.—The Hybrid Tea Roses furnish most of the best varieties for town culture, and each year sees the addition of many striking novelties to this section, already the largest, as it is the most popular, and the one best suited to this climate. In the selection of Roses for towns issued by the National Rose Society, the following Hybrid Teas are included: Caroline Testout, Dr. O'Donel Browne, Gustav Grünerwald, J. B. Clark, La Tosca, Mme. Abel Chatenay, Mme. Ravary and Prince de Bulgarie. It goes without saying that the considered opinion of such a body of experts is beyond contradiction, and, for general purposes, there is no doubt this list represents the front rank of town Roses. All are well-known and popular sorts, and few comments are needed. Of the varieties named, only the first four are suitable for exhibition. Prince de Bulgarie and J. B. Clark appear in the list for the first time in the society's catalogue for 1914. The former is a pretty decorative Rose with fine glossy foliage and of branching growth. The colour

being deep rose pink. Of vigorous growth, shapely in habit and fragrant, it flowers very freely throughout the season, and is a fine exhibition variety. Miss Cynthia Forde is rather like a deeply coloured Caroline Testout, and though perhaps a little inferior to that variety in size of bloom, is of far better shape, and has not the vice of occasionally balling over. Mrs. David McKee, an excellent large-flowered yellow, is very free-blooming and of fine habit, and makes a good town Rose. Joseph Hill is also good, both in blossom and foliage, though not quite so free-flowering as the last named, and rather addicted to mildew, though not badly. Mme. Melanie Soupert is becoming increasingly popular in town gardens, and justly so. It is excellent in every way, except that it has also a slight tendency to mildew, which requires to be checked. Its fine foliage, spreading growth and freedom of flowering render it ideal as a garden Rose, and it is quite in the front rank for exhibition. Though not described as yellow, that is the colour most

is *Erica mediterranea hybrida*. It rarely exceeds a foot in height, and often only reaches a modest 6 inches, making neat tufts of green, branching stems and foliage that from December until well into February are smothered with rose pink flowers. It is quite hardy, and appears to do well anywhere, showing preference for a half-shady position in a sandy peat soil. However, peat is not essential, for, like other Heaths, it will thrive in loamy soil to which leaf-mould has been freely added. The one element to which most members of the Heath family object is lime, and it is almost hopeless to try to establish a Heath garden in a very chalky soil.

SOME GOOD EVERGREEN HEDGE PLANTS.

THE following notes direct attention to a number of useful hedge plants with persistent foliage which are suitable for general culture in the British Isles or for certain areas thereof. Attention is drawn to any little peculiarities of culture which particular subjects may require under the respective headings, while those plants are also indicated which are only suitable for certain localities:

Common Holly (*Ilex Aquifolium*).

—There can be no doubt that this is one of the best of all evergreen hedge plants, for not only does it form an impenetrable fence which keeps in good condition for a very long period, but it presents a pleasing appearance also. Although large plants may be used for hedges, it is usually better to start with those which are grown from 2 feet to 4 feet high. Care must be taken that they are well furnished with branches to the base, for if the hedge is commenced with a thin bottom, it is very difficult to induce it to furnish well afterwards. The plants should be inserted from 1 foot to 1½ feet apart, and it is usually advisable to remove the points of the shoots soon after planting. Do not allow much height growth until the lower parts of the hedge are quite dense. Planting may be carried

out in April or September. Other kinds of Hollies are sometimes used for hedges, such as those with golden and silver foliage and the large-leaved Hodgin's Holly. The former kinds are quite appropriate for some positions, but large-leaved sorts are generally inferior to the common Holly.

Common Yew (*Taxus baccata*) is another useful hedge plant, which lasts in good condition for a very long time. In fact, Yew hedges may be seen flourishing at the present time which were planted over a century ago. The Yew, like the Holly, thrives on a great variety of soils, and may be planted throughout the country except where the ground is water-logged. It takes rather a long while in establishing itself, but when it once becomes thoroughly established, growth is fairly rapid. Some people prefer plants raised from cuttings rather than those grown from seeds, owing to greater uniformity of growth. Plant at the time recommended for Holly.

A BEAUTIFUL WINTER-FLOWERING HEATH: *ERICA MEDITERRANEA HYBRIDA*.
The photograph was taken a week before Christmas.

is very variable, ranging from the palest pink to almost an orange shade. J. B. Clark is what is termed a rampant grower, and is difficult to manage. It is quite unsuitable for bedding, by reason of its size, and, unless required for exhibition, should be pegged down or treated as a pillar Rose. Though usually the flower is coarse, it is still the best red Hybrid Tea for general purposes. La Tosca is also a tall grower, though not, like J. B. Clark, an ugly one. It is a most accommodating Rose, and invariably gives a good account of itself, no matter how poor the soil may be, but requires a good deal of room. The other varieties are all of medium height.

Newer Varieties.—As they become established in popular favour, no doubt some of the newer sorts will find their way into the National Rose Society's list. Two that seem to deserve that honour are Lady Alice Stanley and Miss Cynthia Forde. The former is one of the most reliable Roses. In colour it is silvery pink, the reverse of petals

frequently seen in it, the delightful suffusion of amethyst in the young flowers being very fleeting. Rayon d'Or may prove a great acquisition when robust plants are obtainable at a moderate price, if its unfortunate habit of dying back is due only to over-propagation, as is so often the case with new varieties. But it certainly seems to have this weakness in its constitution. Duchess of Wellington is a beautiful decorative yellow, capable of becoming a success in many town gardens. With other varieties I will deal in my next article.

P. L. GODDARD.

A HARDY WINTER-FLOWERING HEATH.

(*ERICA MEDITERRANEA HYBRIDA*.)

THE great charm of the Heath garden is that it provides flowers the whole year round, and this is one reason why Heaths are so rapidly coming into favour. The best of all the winter Heaths

Oval-leaved Privet (*Ligustrum ovalifolium*).—Although this plant is overdone in many places, it cannot be overlooked, for it grows into a fine fence quicker than any other subject, and it is very cheap. Its leaves are evergreen in most places, although in some of the colder districts they may be shed during a cold winter. If plants a couple of feet high are placed from 12 inches to 15 inches apart, a good hedge will result in three or four years' time. It is a good plan to cut the plants back for a distance of from 9 inches to 12 inches during the first year, and afterwards check height growth until the sides are quite dense. Any kind of soil is suitable if manure is applied, and planting may take place any time between early September and April. The golden-leaved variety of this species is also available.

Holm Oak (*Quercus Ilex*).—This tree is not often used for hedges, although it is excellent for the purpose in the milder parts of the country. It stands clipping well, and forms a dense hedge up to 15 feet or 20 feet high. Moreover, it withstands exposure to sea air very well. Being a difficult subject to transplant, it must be planted while quite small, the best periods being late April and early May and September.

Berberis Darwinii may be used for hedges in the Midlands and South, but it should be treated in an informal manner rather than as a very formal hedge, for although it withstands a fair amount of clipping, constant pruning is likely to cause it to become thin about the lower parts. *B. stenophylla* may be used in a similar manner. As a rule, one pruning a year, as soon as the flowers fall, suffices. They thrive in any good garden soil.

Escallonia macrantha.—There are few better hedge plants than this for the South-West Counties, in places where great strength is unnecessary. It forms a very nice hedge from 5 feet to 6 feet high, and may be kept at a width of from 12 inches to 15 inches. Its dark green foliage and pretty, rose-coloured flowers are equally admired. Few plants stand sea air so well or establish themselves better. Planting may be carried on from September to April.

Olearia Haastii is another shrub which is well worth consideration. It gives excellent results in the vicinity of the sea, and also inland. An annual pruning serves to keep it quite dense and within bounds. This pruning should be given as soon as the flowers fade, for by pruning at that time the dead flowers are removed, which otherwise are rather unsightly. It is at its best when allowed to grow from 2½ feet to 3½ feet high. Planting may be carried on at any period during autumn, winter or early spring.

Common Laurel (*Prunus Laurocerasus*).—This is utilised as a hedge plant in some places, but it is not one of the most satisfactory subjects, for it is very apt to become thin about the bottom, and the large leaves look very unsightly if disfigured during the clipping. As a rule, such hedges are usually pruned with knives or secateurs, which,

of course, adds considerably to the labour. The Laurel has an advantage, inasmuch as it thrives in poor, sandy soil, and may be planted in shade.

Lawson's Cypress (*Cupressus lawsoniana*) introduces a coniferous tree which is sometimes used for fancy hedges. It cannot be strongly recommended, for it is very difficult to keep it well furnished with branches about the lower parts. Its great value is as a wind-break. The same remarks apply to *Thuya plicata*, or *T. gigantea* as it is frequently called. Both trees are unsuitable for dry soils and an impure atmosphere.

Common Spruce (*Picea excelsa*).—Although this tree cannot be recommended for general planting, it is well worth consideration for exposed positions on high land, more particularly where the ground

the innumerable other flowers borne out of season owing to the mild weather so far experienced. With the exception of varieties and hybrids of garden origin, practically all of the shrubby Veronics are natives of New Zealand. No fewer than ten distinct Veronics are enumerated in the list of December-flowering plants at Goodwood, issued by the Duke of Richmond and published in our issue of December 20, 1913. Probably the species that has given the best account of itself is *V. Andersonii* and its variety *variegata*, both of which still flower profusely in many parts of the country. The illustration of *V. macrocarpa* is prepared from a photograph taken in a Surrey garden on December 18, where it had been flowering for some weeks past. The graceful *V. salicifolia*, with Willow-like leaves, together with *V. buxifolia*, with Box-like leaves, are also flowering freely this winter. There are certain flowers, like the yellow Jasmine, Winter Sweet and Witch Hazels, that we look for annually among our garden shrubs, but this season we find the list so far extended as to include not only Veronics, but Roses, Rhododendrons, Cytisuses, Hypericums, Rosemary, *Solanum jasminoides* and *Spiræas* in variety.

VERONICA MACROCARPA FLOWERING IN A SURREY GARDEN IN DECEMBER.

is inclined to be wet. In addition to forming good, rough shelter hedges, it is also useful for wind-breaks in nurseries and other gardens. The North American White Spruce (*P. alba*) and the Sitka Spruce (*P. sitchensis*) may be used for similar purposes. All three should be planted when between 1 foot and 2 feet in height.

SHRUBBY VERONICAS FLOWERING IN WINTER.

ALL through December, in suburban and country gardens alike, certain of the shrubby Veronics have been flowering in their full glory. So conspicuous are they in many gardens that they appear to command even more attention than

uncommonly well, showing to perfection and great naturalness not a few of the flowers grown. Happily, the setting is an ideal one, grass verge, tree and hedgerow mirroring into fullest life and beauty all that is best in these easily grown plants. Happily, too, among hardy and half-hardy annuals there is a choice sufficiently large to suit all gardens, their endless colour shades and variable heights only finding a parallel in the continuous flowering of the plants. Hence we may garden with the gayest and tallest of these flowers, or in smaller areas confine our efforts to the little-known, though not less beautiful, kinds which attain but a few inches high. Or we may garden with some of the more important or extensive families alone, some, like the Snapdragons

COLOURED PLATE

PLATE 1484.

GARDENING WITH ANNUALS.

IF among the readers of THE GARDEN there are any in doubt as to the value or possibility of gardening with annuals alone, they have only to turn to the beautiful coloured plate in the present issue to have their minds disabused on the subject for all time. Surely no greater evidence than this could be forthcoming, save that of the garden itself, which also, naturally, would pay higher tribute to colour beauty and good effect than is possible otherwise. Minus the garden, however, the coloured plate—the colour photograph of which was taken in the gardens of the Right Hon. the Countess of Eldon, Tilehurst, near Reading—plays its part

(*Antirrhinums*), that in Tom Thumb, intermediate and tall varieties are capable of affording great galleries of flowers tier above tier in a very remarkable way. Equally remarkable, too, is the fact—not sufficiently appreciated, perhaps—that in each of the sections named identical shades of colour are repeated. These come true from seeds, and are therefore reliable.

Of its importance we have on more than one occasion been impressed when looking through the trial grounds of Messrs. Sutton and Sons at Reading, from whose seeds, by the way, the flowers shown in the coloured plate were grown and by whom the colour photograph was taken, and it is recorded here for the benefit of those who would have their gardens aglow with colour for weeks on end at a singularly small cost. What is perhaps insufficiently realised in regard to annuals generally is not so much their cheapness or variety as, given certain conditions, their possibilities. For example, the Snapdragon is not strictly an annual, though its greatest garden value is only reached by treating it as such, sowing the seeds in warmth in early February to ensure a blaze of colour in July and August following, with other sowings in succession for later flowering. For borders similarly situated to that shown in the accompanying plate, a background might be formed by Sweet Peas in blue, white, scarlet, pink, cream and other shades. By arranging them in isolated, pyramidally trained groups, light and shade would be retained and informality secured. Following these might appear a broad belt of tall crimson Snapdragons, with another of white and a further one of pink of the intermediate class.

Fronting these might be arranged *Godetias* of distinctive colours, than which, perhaps, few plants are half so gay or so profuse in flowering. Then, should space permit and where fragrance is desired—and where is it not?—a broad belt of Stocks should be formed, to be followed again by a Tom Thumb *Antirrhinum* and, finally, a brilliant blue *Lobelia*. Some of these are so faithfully depicted in the coloured plate that they will appeal to all, and for the rest a few suggestions have been added. Where for some special reason a late summer and early autumn display is desired, the Chinese Aster is well worth considering. It is a great family—great in endless colour shades, flower form and varying height; hence of much utility. A fine attribute of the plant is that it may be transplanted almost at flower-time with impunity, so that, apart from specialisation, it is also a plant for the reserve garden, well suited to filling any blank spaces in the border where earlier-flowering subjects have gone before. Then why do not we make much more of brilliantly flowered plants, *Linum grandiflorum* and Tom Thumb *Nasturtiums* for poorest soils and stony banks, where they are most prodigal in flowering, and last, though not least, *Alonsoa*

Warszewiczii, a plant yielding sheaves of brilliant orange scarlet flowers that compel admiration? These are plants to garden with, since, while affording sheets of flowers, they also raise the annual to the topmost rung of Popularity's ladder.

E. H. JENKINS.

ANNUALS BY THE PATHSIDE.

AMONG the annual flowers of lowly stature these are many kinds well adapted for growing beside the pathways that intersect the garden, where

GODETIAS AND WHITE ALYSSUM USED AS EDGINGS TO A PATHWAY.

their beautiful colours, and in some instances delightful fragrance, can be enjoyed to the full. In the kitchen garden annuals are particularly serviceable for this purpose, because during the winter, when it is necessary to wheel manure on to the plots and do other heavy work, the plants have departed, and there is no possibility of damage such as there would be if perennials were used for the purpose.

There is one point, however, that always ought to be fully studied in making edgings of annuals, *i.e.*, a broad edging looks infinitely better than the narrow line that one too often finds doing service in gardens. The wisdom of a bold display is well shown in the accompanying illustration,

where, on the right, *Alyssum Carter's Snow Carpet* is forming an edging nearly two feet wide. The seed of this was sown where the plants are shown about the second week in April, and was first about a foot wide, the plants having spread, as already indicated, to nearly twice that distance by the following September, when the photograph was taken.

This is one of the best annuals for edgings, owing to its dwarf habit, delicious fragrance and long season of flowering. The plants illustrated commenced to bloom at the end of June, and did not cease until November was well under way. On the left is an edging of *Godetia Lady Satin Rose*. This grew rather less than a foot high and continued to flower over a long period, although not anything like the time that the *Alyssum* did. It will be seen that it was sown in a row about a foot wide and did not spread much. There are several other dwarf *Godetias* that might be successfully used for the same purpose.

The following annuals are all dwarf and make good edgings, though the flowers of some are rather fugacious: *Candytuft*, *Virginian Stock*, *Mignonette*, *Lepotosiphon hybridus* (should have a sunny position), *Nemophila insignis*, *Dimorphotheca aurantiaca*, *Silene pendula compacta*, *Phacelia campanularia* and *Saponaria calabrica*. H.

A COTTAGE HOME IN SOMERSET.

AMONG the counties of England, Somerset is one of the most varied, both as to scenery and geological structure. It has in one part high moorland, in others dense woodland and rich valley, with wide stretches of fertile alluvial land. Limestone, granite and coal are all represented, besides the well-known deposits of valuable building stone. The long coastline to the Severn Sea gives a certain mildness and humidity very favourable to vegetation, and many are the pleasant gardens attached to such dwellings of the cottage type as the one shown in the illustration on the next page, that, roofed with comfortable straw

thatch, nestle in the valleys, well sheltered by the wooded hills.

G. J.

A BEAUTIFUL CLIMBING ANNUAL.

IPOMŒA VERSICOLOR, sometimes known by the name of *Mina lobata*, is one of the most beautiful of half-hardy climbing annuals for summer and autumn decoration. The racemes of flowers, which are of a bright rosy crimson in the bud, afterwards turn to orange, finally changing to pale yellow, are borne in profusion at this time of the year. It is a very suitable plant for covering arbours, trellis-work, unsightly walls, or for trailing up sticks, providing it is in the sun.

THE SWEET PEA IN THE FLOWER GARDEN.

THE garden and decorative value of the Sweet Pea has been somewhat overshadowed by the special attention it has frequently received as an "exhibition" flower; and, while it must never be forgotten that it is owing to the zeal of exhibitors and the keen competition created by them that the raisers vied with each other in producing the exquisite varieties now grown, yet the

Soil and Position.—While the small gardener may not be able to have much choice of position, there is no soil, however poor, which cannot be improved. The most fertile soil is that whose mechanical condition is the finest. All garden soils contain a superabundance of plant food if only it is available, and thus the gardener can, by cultivation, do much to provide a soil in which the roots can have free action, and, given this, the Sweet Pea will flourish. If the soil be light and poor, then a liberal supply of farmyard, and especially cow, manure will help it, while deep digging and incorporating plenty of lime and mortar rubble,

Sweet Pea to the full in the flower garden. It is most effective when grown in clumps, and clumps are very suitable for small gardens. Of course, many people like a continuous row, and if arranged with special regard to colour blending, a delightful result can be obtained. Let me here state that a motley mixture affords me no pleasure; hence my strong advocacy of colour blending. The following twelve varieties, planted in a row, make a pleasing combination: Mauve, Tennant Spencer; white, Etta Dyke; deep cream pink, Constance Oliver; lavender, Florence Nightingale; cream, Clara Curtis; pale pink, Countess Spencer; blue

AN OLD THATCHED COTTAGE, WITH GARDEN, IN SOMERSETSHIRE.

Sweet Pea is first and essentially a "decorative" flower, and one which adorns with equal grace and beauty the garden of the cottage or the mansion, and also one that will thrive and produce a wealth of blossom in almost every kind of soil, and often in most unfavourable positions. The value of such a flower for those whose gardens and resources are limited cannot be over-estimated, and it is to such that these notes are mainly directed. Undoubtedly the "high culture" advocated by exhibitors has been a hindrance to the universal acceptance of the Sweet Pea as an indispensable item in every garden, and the high price of seed has also contributed thereto. These hindrances no longer exist,

combined with winter frosts, will break up the heaviest of clays.

Preparing the Soil.—This work should be done only when the soil is in good condition. Deep digging and thorough cultivation are essential. It is wise to get the ground ready as early in the autumn as possible; yet it is far better to wait for a dry February than to attempt deep digging during wet weather.

Varieties.—For garden and decorative use, those varieties which by experience have been proved to be of sterling merit and not novelties should be grown. The small grower has now nothing to prevent him from utilising the

shades, Flora Norton Spencer; picotee (white ground), Elsie Herbert; crimson, Maud Holmes; lilac, Winsome; bicolor, Mrs. A. Ireland; and dark maroon, Nubian.

Sweet Peas in Clumps.—In this way the finest combinations and effects are seen. Plant in triangular form (five plants will make a clump), and some very beautiful results will reward the effort. Cream, lavender and pale pink; maroon, lavender and bicolor (Mrs. Ireland); mauve, white picotee and cream; crimson, white and blue; French grey, mauve and white—these and many other combinations which appeal to each individual can be had. The following excellent varieties can all be obtained

A YEW HEDGE AT BACK OF BORDER, SHOWING HOW IT IS TRIMMED AND ROOT PRUNED.

A, A—Narrow trenches 1 foot deep. B, B—The spade is thrust down on lines, severing all roots in its way. C—Flower border. D—Alley. E—Space in which the roots are confined.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

OPINION tends to the word "herbaceous" being used as a general term to include plants hardy and semi-tender, evergreen and suffrutescent, fibrous and bulbous rooted, of annual, biennial and perennial duration, the one requirement of importance being suitability for decorative gardening. At a not far distant date it required some courage to define a Lily or an annual Lobelia as herbaceous, and perhaps Dr. Samuel Johnson's definition "belonging to an herb," just as a herbaceous animal was one whose food was herbs, in contradistinction to a carnivorous or flesh-eating animal, gives the original meaning. Earlier than Dr. Johnson were "annuals, perennials and vivacious" plants, all now fitly comprehended in the one name—herbaceous.

Somewhat similarly the herbaceous border has become the receptacle of a greater number of plants of

diversified characteristics than practitioners a century ago knew of. And it is to those who boldly introduced Dahlias, Roses, Sweet Peas, Pansies and other odds and ends of the vegetable kingdom into their borders that we are indebted for the breaking down of the wall of partition between the old-time strictly herbaceous border and the modern border and garden of all sorts. These remarks lead me to say that in the notes which follow there will be found no arbitrary botanical distinctions, so long as plants provide their quota of beauty of colour or of form, or both, that will be esteemed a sufficiently good reason to include them among herbaceous plants.

Position is of slight importance. Any exposure suits, but the plants flower earlier or later accordingly, and late-flowering species should never be planted where the chances are against them flowering at all. Shelter from wind is very important, and where there is none it must be provided. A wall is not nearly so protective as a tall hedge or living screen, which disintegrates the volumes of forceful air into minute and impotent particles, whereas the wind sweeps over a wall in gusts, which, swirling among the plants, twist them about confusedly. The wall itself ought, therefore, to be protected by efficient vegetation. In connection with shelter, that of a proper backing may be considered. The handsomest in summer is a tall trellis furnished with Roses, or with these and other climbers, the *corp d'œil* when these and the border flowers are all out being superbly fine. Frequently advantage is taken of shrubs, which also afford shelter. The fear of these robbing the legitimate occupants of the borders of food is very real to some people, but with care these need never offend. One way is to turn a narrow and deep trench at biennial intervals in the space between the shrubs and the flowers,

all the roots coming in the way being severed in the operation. Another method is to permanently divide the shrubbery from the herbaceous border by means of a narrow concrete wall sunk at least 30 inches into the ground. It need be no more than 3 inches thick, and the concrete one of cement to seven or eight of gravel or small stones. I am partial to Yew for a backing. It forms a remarkably close and warm hedge, is always neat and of a pleasing green, and in some states of the atmosphere is quite beautiful. The roots are kept within bounds in the way mentioned for trespassing shrubs, the method being shown in the accompanying sketch. The hedge needs trimming annually in July or August, and in some years also in spring, the beauty of its surface being enhanced by repeated trimming. A suitable height is 6 feet 6 inches to 7 feet, and 3 feet through, the sides having a slight taper, though not enough to be perceptible to the ordinary gazer. Thuja Lobbii makes a nice hedge, but not nearly so pleasing in the quality of greenness as Yew, and, of course, there are other plants, but none so proper as these. For a summer hedge Sweet Peas are very recommendable. Walls, to revert for a moment to these, may be of almost any height, a terrace wall perhaps only a few feet, and the border should not be wider than 7 feet or 8 feet, and, as a rule, no very tall plants used in its furnishing.

It is becoming usual to run a herbaceous border alongside one of the garden walls, which are generally 12 feet to 14 feet in height, permitting the employment of a great variety of climbers and others not exactly climbers, but which ask for the protection of a wall to succeed. I know of one garden in which Sweet Peas are trained up the wall, but this cannot be recommended for general adoption. Very high walls, along with ample ground space, provide splendid opportunities for bold planting for massive groups of Hollyhocks, Bocconias, Helianthus and such like. The border can hardly be too wide. Clematises do well on high walls, not only *C. montana*, but the beautiful hybrids also; and Banksia Roses love just such a chance to extend without a check. The old

EDGINGS FOR HERBACEOUS OR MIXED BORDERS.

in cheap packets: Apple Blossom Spencer, Asta Ohn, Clara Curtis, Constance Oliver, Countess Spencer, Elsie Herbert, Etta Dyke, Flora Norton Spencer, Florence Nightingale, Frank Dolby, John Ingman, Maud Holmes, Mrs. Ireland, Mrs. H. Sykes, Mrs. C. W. Breadmore, Mrs. Townsend, Nubian, Tennant Spencer, Winsome and Lady Grisel Hamilton, Lord Nelson and Dorothy Eckford of the grandiflora varieties. It will be noticed that I have excluded all those varieties which require shading and protection from the inclement weather in order to produce their true colours, as such varieties cannot be classed "useful garden flowers." Of the Sweet Pea from the floral decorative point of view much can be written, as few flowers lend themselves more readily for the table decoration, the button-hole or the bouquet, &c., and to a Sweet Pea lover no present is nicer than a bunch of these lovely flowers.

The Sowing of Seed: Spring Sowing.—Space does not permit of a full treatment of the relative values of autumn or spring sowing, or of outdoor or indoor sowing. Suffice it now to say that the most satisfactory method for the small grower is to raise the seedlings in a 5-inch pot, which will well hold the five seeds of each variety grown. In January or February sow in good soil half an inch deep, with sufficient sand to keep the soil open. The seeds with whitish coats require more sand than the others, and less water, as they do not germinate so well and rot more easily. Place near the lights directly the seedlings appear, and give cool treatment until mid-April, when they can be transplanted into their permanent quarters.

Staking.—This subject will receive special treatment in a separate article shortly; but for the small garden, the tallest and twiggiest of Hazel sticks form the most artistic and satisfactory supports. During the summer keep the hoe going to check both weeds and evaporation, and rigidly use the knife in denuding the plants of every faded blossom before the seed pod can form. In this way the supply of blossoms can be continued well into the autumn, and the Sweet Pea will prove itself to be the Queen of Annuals, and one pre-eminently suited to small gardens as well as to those of the mansion.

S. M. CROW.

Queen of the Belgians is another estimable Rose for such a position.

Almost as important from an æsthetic point of view is the edging, or whether an edging should be provided. If the walk is grass or the border a part of a lawn, the question is, of course, settled in the negative; and where paved walks separate the border from other parts of the garden, there also an edging may be dispensed with. But pavement is at best a bald setting for flowers, and those who introduce it might well consider the simple method adopted by seventeenth century gardeners, which consisted of grass next the flowers and pavement in the middle part of the walk. Another still older way of dividing off the borders was usual up to the time of Henry VIII., and we read of its employment in Scotland at the same period. That was by means of a framework of wood, sometimes pales, sometimes openwork, as in "The Gardener's Labyrinth," and while its utility was unquestionable, its adoption to-day would open the way for novel methods of gardening not yet attempted. Bones, pebbles, bricks, stones and wood have all been used, and of these brick may still be recommended under certain conditions. Stones in the way of a rockery edging are not uncommon, but their use sometimes passes into misuse, which being walk and which border being difficult to determine. Some folks dislike Box, but undoubtedly of all live edgings it is the most suitable, being easy to keep in order, provided it is clipped at regular intervals, and always neat and of a pleasing green. There are a great number of varieties, some unsuitable. The best is that known as the Mouse Ear, a small-leaved, deep green, slow-growing form, which is common in Berwickshire. Those who want a taller-growing variety will find it in a Continental form which seems intermediate between the common and the dwarf Box. It is used here in an Old English garden, and I have seen the same variety also at Manderston, where it is used in the Italian garden. Box, I think, is best trimmed flat on the top, with straight sides, as shown at D in the sketch on the opposite page; but many have it rounded, and sometimes we find it cut triangular fashion. Thrift (*Statice Armeria*), *Gentiana acaulis*, Pinks, Daisies, Thyme and *Lychnis Viscaria flore pleno* are other plants suitable for edgings.

R. P. BROTHERSTON.

(To be continued.)

WINTER TREATMENT OF LAWN TENNIS COURTS.

NOW that the playing season is over, the groundsman should at once set about renovating the worn-out parts, and where the turf has been subjected to so much wear and tear, fresh turf must of necessity be laid down. I am frequently called in to advise as to this work, and I must say I am surprised sometimes that the greenkeeper in charge should advise the importation of turf that is quite unsuitable for the purpose, as, when it is put down, its texture, compared with the other turf on the courts, is quite different, and during the whole of the next season, until it gets worn bare again, looks out of place, with the result that the court looks very bad indeed.

To remedy this I would advise all lawn-owners to, if possible, patch the bare and worn parts from the sides and ends of the ground outside

the playing area, and returf this part or sow down with turf as near as possible to the same texture as the court itself, as with careful attention this can be easily worked up during the season—as there is no play on it—to almost the same condition as the turf on the court. Another point in regard to this turfing of the ends, which must of necessity be done year after year, is this: the soil below must be removed from time to time and fresh soil substituted, otherwise, no matter how good the turf, the results will be found to be very disappointing indeed. This returfing should be carried out as soon as possible after the courts are closed for the season, so as to enable the fresh-laid turf to get well "knit" together for the next season's play.

All inequalities or hollows should be raised, and the best way to do this is by simply folding back the turf, not cutting it clean out, filling up to the desired level land replacing the turf again. By folding or rolling back the turf, the number of joints are lessened and a better job is made.

The Best Top-Dressing.—After this work has been carried out, the whole green or court should

tennis court, or, indeed, of any lawn, namely, mowing and rolling. I shall take the case of the mowing first, as I consider it the most important. There is a mistaken idea that if the grass is kept cut short during the winter months, the frost and cold will surely kill it. Now, I wish to point out that this is all wrong, and I strongly advise the mowing of the grass. When I say this, I mean that it ought not to be allowed to grow any longer than what it was in the playing season; in other words, keep it as close as possible and always mow when it requires it, as it will harden the grass, make it thicken out, and, when the playing season comes round, the surface will be a great deal more truer and firmer from the commencement. If, on the other hand, the grass is allowed to grow without being mown, it will get thin, and when the spring comes the greenkeeper has practically to set about doing his best to manufacture a new playing surface.

Rolling in Winter.—The other point is rolling, and this is hardly less important than the mowing. How often does one see, after heavy rain, the iron roller at work for all it is worth to, if you

PLAN OF SINGLE AND DOUBLE LAWN TENNIS COURTS.

1, 1—Side lines for double court. 2, 2—Side lines for single court. 3, 3—Base lines. 4, 4—Service lines. 5, 5—Half-court line. 6—Net. 7, 7—Run back at least 12 feet.

be top-dressed with a dressing of good mould (not sand) and well-rotted manure, mixed. This dressing should be well rubbed in, and on no account allowed to lie on the surface.

Worms in the Soil.—Remove all worms from the soil, as a true playing surface is absolutely impossible when they are allowed to burrow and throw up their casts all over the surface. By their removal a firm, true, clean and level surface is obtained, which could never have been got if they had been allowed to remain in the soil. It may, to some people, seem like heresy when I say remove the worms, as it has always been held that worms are the natural drainers of the soil, and that if they are removed the ground will become waterlogged and the turf die out; but this idea is all wrong, and I have proved it so. I strongly advise the removal of every worm if possible. The most effective, simple, safe and non-poisonous worm eradicator I have found is that supplied by Messrs. James Carter and Co.

Mowing.—I now come to a very important part of the winter treatment of the grass on a

ask, make a nice, smooth surface! A good piece of turf can very easily be ruined by the injudicious use of the roller, especially during the wet winter months. I have seen lawns and tennis courts—which I have been told a few years before were in perfect condition—that had got into a very bad state indeed, and this has nearly always been caused to a great extent through using too heavy a roller and also using it at the wrong time. Never, especially in winter, roll the grass with a heavy iron roller when the surface is wet, as it is simply ruination to the lawn. Keep the grass cut short, and roll when the surface is dry (not wet) if a good, clean piece of turf is desired. The foregoing hints are what I practise myself, and which I find the most suitable for what is aimed at—a true, firm carpet of turf.

PETER W. LEES (Greenkeeper).

Mid-Surrey Golf Club.

[We are often asked for the dimensions of single and double lawn tennis courts. The accompanying plan will, we hope, prove useful to those who are thinking of making new courts. Ed.]

HINTS ON PRUNING AND PLANTING GRAPE VINES.

EXPERIENCED cultivators usually prune their Vines at a given time year after year. Amateurs who have not had much experience in this work may be undecided as to how and when they should do it. The following brief hints will be of much service to them. The enthusiast who has had much to do with Vines will easily perceive the good quality of some of the buds and shoots on which they are borne, and be able to forecast, fairly accurately, the quality of the crop of bunches that will result the following year. Now, this knowledge will enable the cultivator to prune to the right "eye" or bud at the base of each shoot of the current year's growth. When

embryo bunch of Grapes, so that if the inexperienced cultivator will closely examine each branch before pruning and then prune judiciously, he will reap a good harvest of bunches. It is bad policy to leave three or four buds, as though they may, and very likely will, produce bunches, the latter will be loose and long-shouldered, whereas the bunches on shoots growing from the first or second basal bud will be compact in form and the berries colour better.

Young Vines require very careful treatment. Too often the amateur cultivator is tempted to leave the rods too long. If a young rod is now from 7 feet to 12 feet long, the cultivator should not hesitate to cut it back to 2 feet from its base. If so pruned every year the Vine is gradually built up and so fills the house, and there will be no loss of Grapes in the meantime. As many bunches as it will be advisable to leave on can be secured

pruned by the middle of January; but if the work can be done in the last week in December, so much the better, as there is very little risk of bleeding when the sap rises again in spring. The cut ends of branches pruned late should always be painted with knotting or styptic to prevent bleeding.

The Black Hamburg is a splendid variety for amateurs to grow. It is one of the best for general use. The Vine grows freely; ripens its wood early, even in adverse seasons; it is free in the production of bunches; the berries and bunches are large and well coloured when properly treated; and the flavour is superior to that of many other varieties. The Vine will succeed in a cool house, but deserves the assistance of artificial heat.

Hints on Planting Vines.—Amateur cultivators must not attempt to make very expensive borders. Thorough drainage is essential. If the subsoil is not gravelly or porous, a drain should be laid from it to the nearest outlet. In every case it is advisable to put in a layer, 9 inches deep, of broken bricks, and on them whole turves, grass side downwards, before putting in the main body of compost, which should be about two feet deep. Fibrous turves chopped into pieces about four inches square, with a pound of half-inch bones to each bushel, will constitute a good rooting medium for Vines. Feeding can be done at any time during the growth of the Vines and when they need nourishment. Borders may be made inside the house, outside the house, or partly inside and partly outside. In the latter case the Vines are planted inside and the roots allowed to permeate both the inside and outside border. If the space available for the border is 12 feet wide, it should be made up in sections 4 feet wide the first year, adding 2 feet each year afterwards. Very fine Grapes may be grown if the border is only 6 feet wide. The Vines should be planted in January. Carefully remove the soil and spread out the roots evenly, covering them with finer soil 4 inches deep and make the soil firm. Prune back the rods at once to within 18 inches or 2 feet of the ground level. During the

A FINE CROP OF BLACK HAMBURG GRAPES. NOTE THAT THE VINES ARE GROWN ON THE SINGLE ROD SYSTEM.

it has happened that the main basal leaves have been lost prematurely during the growing season, the buds have also lost much valuable support, and, instead of growing round and plump, they assume a pointed form and are not at all prominent. The round, plump bud generally contains an embryo bunch of Grapes, and it is quite safe to prune the branch back to that bud. The pointed, shrivelled bud rarely contains an embryo bunch of Grapes, and so it is unsafe to prune back to it—that is, to leave only that bud at the base of the branch—as if it is the only one left, there will be no Grapes the following year. The safe plan, in such circumstances, is to leave two basal buds. The one next to the old rod, or spur, as the case may be, will duly break and grow, but it must be rubbed out in due course when an inch long. The other bud, however, will very probably contain an

every year. Suppose, however, that, instead of cutting back the young rod as advised, it was left three parts or its whole length. When the sap began to rise in spring it would cause the few buds at the extreme end to grow while the others remained dormant. Under the treatment of an experienced cultivator this would not happen; but I am now referring to the way that an amateur without experience would find the new growths come. When only the top buds grow, a vacant space is left below, and in future years there would be an unequal disposition of side branches on the Vine rods. Do not cut too close to the buds. Leave quite half an inch of stem beyond the bud; also use a very sharp knife so as to avoid splitting the branch. It is well to hold the rod firmly with one hand while making the cut with the other. All Vines should be finally

year train up a leader and one shoot on each side of the Vine when the latter is grown on the single rod system. This system also requires that the Vines should be planted at least 3 feet apart. Let the new shoots grow slowly the first year, simply keeping frost out of the house.

It is not a wise plan to leave any bunches on the Vines the first year. In the second year a few bunches may be left to ripen, depending on the strength and vigour of the Vine rods. It is quite a mistake to overcrop a young Vine, for by so doing it is weakened in constitution at a time when its youthful vigour should be centred on building up a sound foundation for the heavy crops the rods are to carry for many years to come.

G. G.

GARDENING FOR BEGINNERS.

IVIES FOR LOW FENCES, RUSTIC TRELLIS AND SCREENS.

1.—CHAINS IN POSITION BEFORE PLANTING.

2.—IVY TRAINED TO A LOW RAILING.

THE common Ivy of our hedgerows and woods is familiar to all. The numerous and beautiful varieties grown in nurseries for sale are not so well known, as, unfortunately, there are some who regard the Ivy as too common to plant in gardens. The green-leaved sorts are the easiest of all plants to propagate from cuttings. Young shoots pulled off a wall or from an Ivy bank root readily in most soils. The orthodox method is to make cuttings 6 inches long and dibble them firmly in a prepared bed on a half-shaded border, 4 inches apart in the rows and 9 inches from row to row. The prettily variegated sorts root better in pots filled with sandy soil in a cold frame. This work may be done at any season of the year, October to January being the best time.

Where to Plant.—Ivies are the best of all evergreen climbers, and thrive in nearly every soil and position. Their value to form an attractive low fence, as a terrace boundary, or a dividing line between two parts of a garden, is well depicted in the illustrations. The Ivy is equally well adapted for clothing a rustic trellis, screen, and wooden or iron fence to secure privacy. The choice, weaker-growing sorts are often most effectively used on low terrace walls, while the vigorous varieties may be employed to clothe bare walls of buildings, particularly those having a northern aspect. Ivy edging, when kept neatly trimmed, forms an excellent margin to a shrubby border or a large bed on a lawn, while for clothing bare ground beneath trees and sloping banks the Ivy is unrivalled. The value and beauty

of the Ivy in our gardens depend to a very great extent on it being properly tended and trained. While Ivies will grow in most soils, the green sorts may be encouraged by manuring the ground previous to planting. To do this, however, to the choice variegated sorts seems to encourage them to revert to the green forms, which must, of course, be removed as soon as noticed. These beautiful variegated Ivies, it has been noted, make very good growth in soil containing old lime rubble and broken bricks. Though self-clinging when the plants become established, against a wall or fence a little training is necessary in the first instance. A few shreds and nails should be used to hold the shoots in position on the wall or wooden fence till the roots push out and fix themselves. It will be necessary to tie the young growths for some time to iron fences and low rails similar to those illustrated. It considerably improves the appearance of the stronger-growing green sorts if in April each year, just previous to new growth starting, they are closely trimmed back to the wall or fence with shears, removing many of the leaves and loose shoots. The plants certainly look rather bare for a week or two, but the beautiful fresh green appearance of the young leaves a little later far outweighs this. The training of the choice, weaker-growing variegated sorts is a rather different matter. From time to time the loose shoots, if required, must be fixed in position till the plants cover the allotted space, when they should be cut off singly with a knife. A low chain fence, such as that shown in the

illustration, can be completely clothed in two years if strong plants in pots are purchased for planting. It is quite a simple matter to erect one of these low railings or fences. Upright iron posts should be driven into the ground at suitable distances. Those shown in the illustration are 7 feet 6 inches apart; this may be increased to 10 feet if desired. The height of the posts above the ground may be 2½ feet to 3 feet, with a hook on the top of the posts on which to hang the chains. A second style is to have a straight rail, generally of barrel iron, instead of the looped chains, while a third method with two rows of Ivy is also illustrated. It is just a matter of taste which method is adopted; the Ivy will clothe all equally well.

A Useful Selection of Varieties is as follows: Green-leaved sorts: *Acuta* (*amurensis*), large, bold leaves; *canariensis* (the Irish Ivy), the best sort for growing beneath trees and fences; *dentata*, large, glossy or leathery green leaves; *Emerald Green*, a rich, bright green Ivy; *palmata* (the Five-fingered Leaved Ivy), a very nice variety; *sagittæfolia*, triangular or three-lobed leaves, very distinct; and *rægnieriana* (the Giant-leaved Ivy), very large, leathery foliage. Variegated sorts: *Angularis aurea*, leaves bright gold; *argentea variegata*, leaves margined and variegated white; *dentata variegata*, creamy yellow variegation; *digitata aurea*, golden yellow foliage; *flavescens*, bright yellow, small leaves; *Lee's Silver*, silver margin; *maderensis variegata*, broad silver band; *Mrs. Pollock*, yellow-blotched leaves tinged with red; *Silver Queen*; and *variegata elegantissima*, silver-edged leaves.

3.—SINGLE CHAIN MARKING A TERRACE BOUNDARY.

4.—A DOUBLE CHAIN CLOTHED WITH IVY.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Foreword.—In writing this calendar for the ensuing year, I will endeavour each week to give short reminders of work which should be carried out in as many branches of gardening as space will permit; but it should be remembered that soil and situation are important factors in gardening, therefore each cultivator should determine for himself how far such circumstances should affect his practice.

Fruits Under Glass.

Melons.—If ripe Melons are desired in May, a sowing should be made at once in small, clean pots and placed over a brisk bottom-heat. Protect the seeds from mice by sheets of glass. The temperature of the bed may be about 75°. When the young plants are through the surface, keep them as near the glass as possible. Eminence and Hero of Lockinge are good varieties for early sowing.

Pot Vines, to be of any value in saving the energies of permanent Vines, should be well advanced and showing their bunches. At this stage a night temperature of 65° should be maintained. Particular attention should be given to stopping the most forward shoots, so that an even spread of foliage may be secured over the trellis. Examine the pots several times daily and water with great care.

Early Permanent Vines.—When the shoots are fairly on the move, the Vines should be tied securely to the trellis. Delay in this matter will cause the young shoots to become drawn. When double breaks have been reduced and the bunches become prominent, the temperature may be raised to 65° at night, rising to 80° by day with sun. Maintain a moist atmosphere by damping the floor and walls several times daily.

Strawberries.—If not already done, a batch of the most forward plants should be placed in gentle heat. There is no better place to start these plants than a flat pit over a bed of leaves. The gentle heat produced by the leaves will encourage root action. The pit should be freely ventilated, or the foliage may become drawn. When the flower-spikes begin to push, the plants should be moved to a forcing-house with a temperature of 55° and placed near the glass.

The Plant-Houses.

Mignonette may be sown now for flowering in May. Three-inch pots are best for the purpose, as the plants can be potted into larger ones as growth advances. The soil may consist of three parts rich loam and one part decayed manure, and should be made firm before the seeds are sown. A temperature of 50° will suit them well.

Flowering Shrubs.—Lilac and other flowering shrubs intended for forcing should be potted at once. They may be put in some sheltered position and placed in heat as necessary. The same remark applies to bulbs which have been potted and placed in ashes.

Chrysanthemums.—Early struck cuttings should be removed from the propagating-pit as soon as they are sufficiently rooted, or they may become drawn and the prospect of a satisfactory result much reduced. As the flowering plants are cut over, a sufficient number should be placed near the glass in some cool structure, so that stocky cuttings may be produced. There should be no delay in taking the cuttings until the full stock has been secured.

Hardy Fruit.

The open weather experienced during the autumn has been all in favour of planting, which should be finished with as little delay as possible.

Apricots.—In planting young trees it should be remembered that over-rich soil frequently causes canker, and when once a tree is attacked by this disease, it is a difficult matter to restore it to health. Apricots should be planted in rather poor soil with plenty of old lime rubble, top-dressing the borders when the trees reach their fruiting stage. Established trees should be pruned without delay. Retain as much young wood as may be necessary to fill in the space on the wall, but the shoots should be cut back in proportion to their strength, so that young spurs may be produced regularly over the tree for next season's crop.

The Kitchen Garden.

Carrots in Pits.—A sowing of Stump-rooted Carrots should be made over a gentle hot-bed as early in the year as possible. Brick pits without fire-heat are best for this purpose, but protection from frost must be provided by covering the pits with Fern or other dry material.

Peas.—A small sowing of Peas may be made on a warm south border as soon as the state of the soil will permit. The seeds may be sown in deep drills and covered with 2 inches of fine soil.

Digging and Trenching should be pushed forward as quickly as possible while open weather lasts. It is a good practice to trench as much ground as possible each season, and if the weather is dry, the heavy ground should be turned up first, so that the soil may be exposed to the influence of the weather as long as possible.

The Flower Garden.

Herbaceous Plants.—There is no other class of flowering subjects which has grown in public favour in recent years like herbaceous plants, and none which will afford a greater profusion of bloom from spring until late autumn. The arranging of these plants must depend greatly on the situation, so that no hard-and-fast rule should be adopted. The ground in which they are to be grown ought to be trenched 2 feet deep, and if of a heavy nature a quantity of wood-ashes or decayed leaves should be mixed with it.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

General Work.—Early in the New Year much may be done in pushing forward such work as trenching, more particularly plots that are inclined to be heavy. Take advantage of frosty weather to wheel on manure and other refuse, so that it may be at hand when the weather permits of digging. On all occasions ground intended for Peas should be deeply trenched. This will prevent them suffering from drought.

The Seed Order.—No time should be lost in making up the seed order; it will save valuable time later, besides being much appreciated by the seedsmen.

Rhubarb and Seakale should be lifted, and allowed to remain on the ground until required for forcing. Three or four good-sized Rhubarb roots put in the forcing house from time to time will keep up a constant supply.

Hardy Fruit.

Planting.—Any planting still to be done should not be delayed, provided the soil is in a fit state; but if it is the least pasty, defer it until it dries, as it is a great mistake to plant in such soil.

Pruning.—The pruning and nailing of Apricots and Cherries should have first attention, as the buds will very soon be on the move. In the case of Apricots it will be well to put a double net over the trees; this will protect the more forward flowers, and it is more convenient to do this now while working with them. The pruning of standard and all bush fruit should be completed without delay. If one could afford the time, all fruit trees and bushes should be pruned immediately the fruit has been gathered. The reason for this will be quite obvious to all who have the least pretension to fruit-growing. In pruning wall trees, opportunity should be taken to cut away a number of spurs that have got out of bounds, and if a few are removed each year, it is surprising how soon a tree may be renewed.

The Flower Garden.

Trenching.—Borders devoted to annuals are better trenched two spits deep, and if a quantity of decayed vegetable refuse and mown grass collected from the lawn during summer is put in the bottom of the trench, it will assist in preserving moisture and also act as a fertiliser. Any dividing or planting of herbaceous plants had better be deferred until March. Should plants arrive from the nursery or from friends, it will be much better to place them in a cold frame, or, if they are very choice, place them in pots and protect from frost.

Montbretias.—In a great many districts, even in the North, Montbretias will stand out all the year. Last year I lost every bulb, whereas I had not been in the habit of lifting them. It will be well to run no risks, and to lift them, select the largest bulbs, and store them in an outhouse.

The Rose Garden.

Planting.—Roses may be planted up till March when the weather permits; but should the soil not be in a fit state for planting, when the bushes arrive they may remain unpacked, but kept in the matting until they are to be planted. Afterwards do not mulch with heavy farmyard manure. This is apt to keep the soil cold and wet; indeed, I believe we lose more Roses through this cause than from any other. A few pieces of Bracken or other dry material will be all that is necessary to protect them from frost.

Plants Under Glass.

Carthagens.—The greatest possible care should be exercised in watering at this season, particularly those of the Malmaison type. Over-watering at this time often leads to rust, which should be guarded against at all costs. Indeed, until about the middle of next month very little water will be required. Admit air freely, and only use fire-heat on damp, foggy days.

Carnation Rust.—Keep a sharp look-out for the Carnation rust, which makes its appearance at this season and spreads with alarming rapidity. As soon as any spots are detected, cut away the affected grass and burn it.

Cuttings of the Perpetual-flowering varieties should be inserted now. Better results will, in all probability, be obtained from cuttings rooted now than from those rooted earlier. For rooting I find nothing better than boxes filled with pure sand and placed in a house where there is a little bottom-heat. Should the cuttings be sturdy, they will not require to be covered with glass.

Late Chrysanthemums will still provide a fair amount of flowers, but provision must be made to keep up the supply. Place a few Azalea mollis and Lilacs into heat, and Freesias may be gently forced.

Cyclamen.—I know of no plants that give more satisfaction at this season of the year than some well-grown Cyclamen, the variety Salmon Queen being particularly attractive. Begonia Gloire de Lorraine will be getting over, and should be partly cut back and kept on the dry side for a time. Plants that have been used for house decoration are seldom much good for producing cuttings, and it will be just as well to do away with them at once.

Violets in Frames.—In unheated structures the greatest care should be taken in admitting air, and see that all decayed leaves are picked off and burnt. Keep pinching runners off, and stir the soil between the plants frequently with a hand-fork. I find a sprinkling of ground lime between the plants tends to keep them in a healthy, growing state.

Fruits Under Glass.

Peaches.—No time should be lost in completing the washing of the houses and trees and tying up the shoots, as the buds soon begin to swell with the increased sun-heat. In arranging the shoots, overcrowding cannot be too strongly condemned; 4 inches between the shoots will be a good guide. After attending to the border, finish up by giving the pipes a coating of lamp-black; it gives the house a much cleaner appearance, besides preserving the pipes.

Vines.—By this time most of the work in the vineries should be completed. Unless in the case of rods infested with mealy bug, the scraping of them, even with a blunt knife, should never be resorted to. All that is required is to rub off any loose bark with the hand.

Painting the Rods.—I know of nothing more effectual than a mixture of soft soap, sulphur and a little petroleum, mixed in boiling water, for this purpose. Brush this well into the rods and spurs with a stiff paint brush, which should destroy any eggs that may be lodged there; besides, this preparation is an excellent preventive in warding off red spider.

JOHN HIGHGATE,
(Gardener to the Marquis of Linlithgow)
Hopetoun Gardens, South Queensferry, N.B.

VEGETABLE SEEDS FOR
SPRING AND SUCCESSIONAL SOWING.

WITH such a host of varieties of vegetables it must be extremely perplexing to many, and especially to those who are amateurs, to decide which to select when preparing the seed order at this season; consequently a list of standard varieties, as mentioned below, and the time for sowing, with other particulars, may, I trust, be of some service to those who have not had the opportunity, as some of us have, of testing the varieties named. At the same time, I should like it to be clearly understood that some localities and soils are more suited to certain sorts than others, and, to a certain extent, common sense must be the guiding factor as to this; the same applies to the dates of sowing and the conditions of the weather and soil. It should always be borne in mind that it costs just as much to cultivate inferior varieties as it does the better ones, and though the initial cost of the seeds may be slightly more, the results will more than compensate for the extra outlay.

Preparation of the Soil.—It is of the utmost importance that the ground in all cases should be well drained and deeply and well worked during the winter and early spring. Light, porous soil is best trenched or deeply dug during the autumn and winter, while that of a stiff, retentive nature is better when worked in early spring. Everything should be done, as far as possible, to ensure a fine tilth by the time for seed-sowing. Though dates are given, it must not be assumed that it is imperative for sowing the seed strictly at such time. The weather, of course, has to be considered as well as the nature of the soil. It is far better to wait for two or even three weeks than to make any

attempt, especially on stiff, pasty soils, to sow fine seeds. At the same time, no opportunity should be missed for so doing. Probably the most common mistake made in relation to vegetable culture is sowing the seed too thickly; this is a fault which applies not only to the cottager and amateur, but very largely to professional gardeners. All sorts of excuses are raised for so doing; but, providing the soil is good, as it should be, I have never yet found a satisfactory excuse. It is a mere waste of seed, and overcrowding means in all cases unsatisfactory results. A golden rule, and one I have always tried to follow, is to sow just about as thick again as is needed, and thin to the desired distance as soon as the crop is practically assured.

GARDENING ACROSTICS.

THOSE entering for the acrostics must observe the rules published on page 607 of the issue of December 6, 1913.

DOUBLE ACROSTIC No. 5.

A beautiful hardy spring-flowering shrub whose shoots are wreathed, when well grown, with golden bells.

Firsts—Its generic name.

Lasts—A synonym of its more usual specific name.

1. The surname of the author of what is "perhaps the most beautiful of all herbals."
2. The hardiest Daisy Tree.
3. Once used as a charm; hence my popular name.
4. Not quite.
5. Sacred in the Flowery Land. Its colour and its name.
6. A charm—text and symbol.
7. The result of mating two species of the same genus.

8. "The King of Irises."

9. Hyacinthus non-scriptus. Why? What is supposed to be wanting?

Solutions of the foregoing must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, January 10. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF
ACROSTIC No. 3.

Firsts—"Ars Topiaria."

Lasts—La Fragonine.

EDWIN BUCKETT.

describes † A well-known disease affecting different kinds of trees. See Mr. Lynch's articles in *THE GARDEN* for November 22 and 29, 1913. § Thomas Tusser, who published in 1557 "An Hundreth Good Pointes of Husbandry," enlarged in 1573 to "Five Hundreth Good Pointes of Husbandry." || Lavatera Olbia Award of merit, Royal Horticultural Society, June 18, 1912. Pictured in Vol. XXXVIII., Part 2, of the Journal, and described by John Abercrombie in his "General System of Trees and Shrubs." ¶ Warden Pears and Popering Pears were two well-known varieties of Shakespeare's time. Leland was Rector of Popering.—Ellacombe's "Plant Lore and Garden Craft of Shakespeare," first edition, page 154. ** The Woad-growers of Germany gave indigo the name of Devil's Dye because it began to take the place of woad in dyeing.—Friend's "Flowers and Flower Lore," page 63. †† The cup of the Acorn is botanically called a cupula. ‡‡ Rhodanthe Manglesii is a pretty pink annual, often grown in pots. Its flowers keep their colour a long time when dried. A native of Australia. §§ As starch is stored in cereals and cane sugar in Beetroot, so inulin is stored in Dahlia tubers. |||| Repton was a celebrated landscape gardener of the "natural" school. He seems to have especially disliked formal avenues.—Cecil's "History of Gardening in England," third edition, page 258.

RESULT OF ACROSTIC No. 2.

In accordance with our rules, eleven marks were possible in this acrostic, one for each correct light and one for each correct "first" and "last." The following marks have been awarded:

Eleven marks.—Ernest Ballard, "Tortoise," "Mowgti," R. Chapman, "Shelah," "Penwarne," "Rusticus," "Scotia" and "W. R. D."

Ten marks.—"Ping," "Tentamen," Wm. Bond, "Tempus Fugit," L. Bigg-Wither, "Miller," "Hero," J. Coupland, "Elm," "Judith," G. Tolson, Miss G. H. Jeffreys, L. A. Loudon, G. B. Bassett, "Rustic," "White Lady," "S. W. P.," G. D. King, "Anna Olivier," "Nautilus" and Miss Marindin.

Nine marks.—"Jan," "E. C. F.," "W. J. W.," "Boarsvale," Miss E. A. Patch, "Westbank," "R. P. B.," "M. M.," A. Henderson, H. J. Giblett and "St. Kevins."

Eight marks.—"Briarbank," Wm. Acworth and "P. P."

Seven marks.—Mrs. Devenish.

Two marks.—Wm. Slocombe.

RESULT OF ACROSTIC No. 3.

According to our rules, thirteen marks were possible in this acrostic, one for each correct light and one for each correct "first" and "last." The following marks have been awarded:

Twelve marks.—"White Lady," L. A. Loudon, "Ping," "Hero," "Westbank," "Nautilus" and "Jan."

Eleven marks.—R. Chapman and "Boarsvale."

Ten marks.—"Elm," "W. R. D." and "Rusticus."

Nine marks.—"Miller" and Wm. Acworth.

Eight marks.—"St. Kevins," "Judith" and G. D. King.

Seven marks.—"Tortoise."

Five marks.—"W. J. W."

Four marks.—"Rustic" and Ernest Ballard.

Three marks.—"Tempus Fugit," "Iris" and "Penwarne."

One mark.—"M. M."

OBITUARY.

SIR TREVOR LAWRENCE, BART.

It is with the deepest regret that we have to announce the death of Sir Trevor Lawrence, Bart., which occurred late on Monday night, December 22, at his residence, Burford, near Dorking. Sir Trevor was well known in horticultural circles, having for twenty-eight years acted as President to the Royal Horticultural Society, a position which he relinquished so recently as February, 1912.

THE LATE SIR TREVOR LAWRENCE, BART.

He was born on December 30, 1831, and was the only surviving son of the first Baronet, William Lawrence, Fellow of the Royal Society and Sergeant-Surgeon to Queen Victoria. Sir Trevor was educated at Winchester, and studied medicine at St. Bartholomew's Hospital, afterwards serving ten years in the Indian Medical Service, viz., from 1853 to 1863, which covered the period of the Mutiny. He was a Member of Parliament from 1875 to 1892, first for the Mid-Surrey Division and later for the Reigate Division. Sir Trevor always took a keen interest in hospital work, and for twelve years acted as treasurer to St. Bartholomew's Hospital. In horticultural circles he was one of the best-known personages of his day, and to his initiative and energy the Royal Horticultural Society owes not a little of its present prosperity. He was a great Orchid enthusiast, and his private collection was one of the best in the country. His genial manner endeared him to all those with

whom he came in contact, and by his death horticulture loses one whom it will not be easy to replace. We had the pleasure, by special permission, of dedicating the sixty-ninth volume of *THE GARDEN* to him. Sir Trevor leaves a widow, three sons and a daughter, to whom we tender our deepest sympathy.

The funeral took place at St. Michael's, Mickleham, on Saturday, the 27th ult. Among those present were Lady Lawrence, Sir William and Lady Lawrence, Sir Albert Rollit, Sir Jeremiah Colman, Bart., Lieutenant-Colonel Sir David Prain, Professor Bateson and Mr. Thomas McRow. A memorial service was held at Holy Trinity Church, Kensington Gore, on the same day. Among those who attended this service were the following members of the Council of the Royal Horticultural Society: Baron Bruno von Schröder, Sir Harry J. Veitch, Sir Daniel Morris, Messrs. Arthur W. Sutton, W. A. Bilney, E. A. Bowles, H. B. May and the Rev. W. Wilks (secretary). Mr. D. W. Thompson, representing the Royal College of Horticulture, Edinburgh, was also present.

W. COLLINS.

With deep regret we have to announce the death of the late esteemed secretary of the United Horticultural Benefit and Provident Society, which took place at 9 p.m. on the 21st ult. Mr. Collins underwent a successful operation for stricture in November, and was progressing favourably until about ten days before his death, when he contracted a chill and pleurisy supervened, the end coming quite suddenly and unexpectedly. Every expression of sympathy and respect was shown when the remains were laid to rest in Streatham Cemetery on Saturday, the 27th ult. The first portion of the Burial Service, which was most impressive, was conducted by the Canon at the Church of Ascension, Balham Hill, and thence to the Cemetery, where a large circle of friends had gathered to witness the last rites of their respected friend. Among the numerous and beautiful floral tributes which were sent was a magnificent harp with a broken string, "From the Members of the United Horticultural Benefit and Provident Society. A token of respect and esteem for our late Secretary, who for twenty-five years faithfully served the Society." Messrs. J. Wheeler, A. Stanbridge, E. Burge, T. Winter (treasurer) and A. C. Hill (secretary) represented the society.

JOHN MATTOCK.

It is with regret that we announce the death of the well-known rosarian, Mr. John Mattock of Headington, near Oxford. Mr. Mattock was a native of Bath, but moved to Headington about forty years ago, where he grew Roses with marked success. He was particularly successful in the cultivation and exhibition of Tea Roses, the soil of the neighbourhood being specially suited to this section. Mr. Mattock died on December 22 last at the age of seventy-six years.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Special New Year Number.—We wish to thank the very many readers who have so kindly sent us letters of appreciation respecting our Special New Year Number, published last week. It is gratifying to know that our efforts are so widely and so warmly appreciated.

Mossy Saxifrages in Winter.—At the present time, when most of the occupants of the rock garden are looking far from happy, the brilliant green of the foliage of some of the Mossy Saxifrages is very pleasing. One of the best in this respect is *S. hypnoides gemmifera*, which spreads freely and forms a dense carpet of vivid green that contrasts well with the sombre hue of the rocks. *S. muscoides* and *S. decipiens Sternbergii* are two others that are very effective.

An Attractive Berried Shrub.—The majority of *Cotoneasters* are valued for their attractive fruits, which help to brighten up the garden during the autumn and winter. One of the most valuable for this purpose is *Cotoneaster affinis*, a deciduous Himalayan species often growing into a good-sized tree, when it is an object of beauty, bearing a large crop of fruits, which are an excellent substitute for Holly berries when there has been a scarcity of them, such as has been the case in some places this year.

Primula malacoides.—This charming little Chinese *Primula* is very highly appreciated, and is quite a feature in many greenhouses with its pale pink flowers. Although it may be hardy, in some districts it flowers so late that it is more satisfactory as a greenhouse plant, being well adapted for that purpose. It is quite easily grown, while its free-flowering habit and the time it remains in bloom, combined with the season of the year it flowers, make it a very valuable plant. The white form, although very pretty, can hardly be considered an improvement on the type.

Javanese Rhododendrons.—Unlike all the other *Rhododendrons*, the various garden forms obtained by the intercrossing of *R. jasminiflorum*, *R. javanicum* and other species, natives of the Malayan Archipelago, flower more or less continuously throughout the year. They are sometimes referred to as greenhouse *Rhododendrons*, but this is such an elastic term that it conveys but little. If a greenhouse is regarded as a structure from which frost is just excluded and nothing more, it will not be warm enough to do full justice to these beautiful flowers. They need a minimum night temperature of 50° to 55°, with a rise of 10° to 15° during the day; a fairly moist atmosphere is also necessary to their well-doing.

Hippeastrums.—These brilliant greenhouse flowers have been much improved in the hands of the hybridist of late years. The flowers most sought after are of good colour without the green base, and having the perianth so arranged

that the segments overlap one another without showing daylight between. The flowering bulbs should now be placed in heat and given every encouragement in the way of top-dressing and subsequent stimulants, in order that they will send up good, strong inflorescences.

Strawberry Fruits in December.—While visiting the gardens at Amberwood in Hampshire on December 17, we noticed many fine trusses of fruits in various stages of development on plants growing in the open borders. Many flowers were to be seen in various parts of the two large plantations, and on close inspection it was found that both spikes in flower and those bearing fruits were growing from side crowns or runners very close to the parent plants. Numbers of fruits were as large as Walnuts. The variety was *Royal Sovereign*.

Roses in Windy Situations.—After the frost experienced a week ago, it will be advisable to look over the Rose-beds, particularly in windy situations and where the soil is heavy clay. A day or two ago we noticed that a number of bushes had been blown about so much as to cause a collar of soil round the stem, and this was in some instances filled with water. The soil ought to be broken up and then made firm round the stem, and, if necessary, a stake put in to support the bush. Newly planted Roses will probably have been loosened by the frost, and where this is so, the soil must be made firm without delay.

The Sea Buckthorn.—Now that the berries of many hardy trees and shrubs have been devoured by birds, the value of the Sea Buckthorn, *Hippophaë rhamnoides*, is more fully appreciated. By the lakeside at Kew there are some large bushes covered with the translucent orange-coloured berries, which are very beautiful indeed when kissed by the winter sun. Although this is a rather slow-growing shrub, it is not fastidious as to soil and situation, but care must be taken to plant one male bush to about every eight or nine of those capable of bearing fruit, otherwise the berries will not be formed.

A Beautiful White-Stemmed Bramble.—At the present time the outer fringe of the garden, just where it merges into the woodland, owes most of its charm and interest to those shrubs with either coloured stems, fruits or leaves. In the first category we have Dogwoods, Willows, Brambles and several other kinds that might with advantage be more extensively planted for winter effect. A new Bramble from China named *Rubus giraldianus* promises to be particularly valuable in this respect. It sends up a colony of stout stems some 8 feet high, which are almost as white as driven snow, and as they are pendulous, a well-grown bush forms a very striking and beautiful feature in the landscape. In planting these coloured-stemmed shrubs it should be remembered that the best effect is obtained when a background of dark-leaved conifers or other evergreens is secured.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Arum Flowering Outdoors on Christmas Day.—

I thought it might interest some of your readers to hear that there was an Arum, or Lily of the Nile, in flower outdoors on Christmas Day at a cottage near here. The plants have been outside all the year round. They do not generally flower before April.—F. O'CONNELL, *Darrinane Abbey, Waterville, County Kerry, Ireland.*

Permanent Netting for Fruit Trees.—Those who suffer much from birds among the bush fruits (and who does not?) would do well to consider, if they have not already done so, the advisability of erecting wire-netting as a permanent protection. We did so here last year, with most gratifying results. In the vicinity of trees it is well only to enclose the break with 6-feet netting, and in the fruit season cover the top with good tanned netting, or else to have the overhead netting in span-roof form to throw off the falling leaves in autumn. The birds are most persistent round the sides. Last season, although we supplied water to the birds in saucers, we could not make one break of small fruits bird-proof, even with double tanned nets.—C. COMFORT, *Midlothian.*

Laurustinus lucidus.—One may pass through many a good garden and never see a bush of this beautiful shrub, with its handsome, polished foliage and large cymes, $3\frac{1}{2}$ inches across, of half-inch-wide, pure white blooms and rosy tipped buds. Its beauty has been conspicuous of late, for whereas it is normally a spring-flowering shrub, the unusually mild weather in November and early December has pushed it forward into a flowering state and the bloom has been perfect and abundant. It is a little tenderer than the other garden kinds, the hardiest being the Black Laurustinus that has [the handsome berries with the blue metallic lustre; but anywhere south of London it is likely to do well in a sheltered place. The whole growth is rather more free than that of the common Laurustinus, and, although the bloom is so much larger, it is a more refined flower and has also a certain kind of graceful port that is wanting in the more stiff and twiggy common kind.—G. J.

Peculiarities of Mistletoe.—Herefordshire being mentioned by "C. Q." on page 644, December 27 issue, as being favourable to the finding of Mistletoe in its orchards, gave me, as a Herefordian, an added interest in the reading of the article. May I ask if any reason is given, or can be suggested, why Mistletoe refuses to grow on Pear trees? assuming such to be the case. I happened to read an article in a contemporary last Christmas-time on Mistletoe, and the Pear tree was given by the writer as a tree upon which it had been found. But this may have been a mistake on his part. I cannot recollect seeing Mistletoe on a Pear tree anywhere; neither can my father, who has had much to do with orchards all his life; nor another Herefordshire fruit-grower of whom enquiries have been made since the appear-

ance of your article in THE GARDEN. In addition to the trees mentioned by "C. Q.," perhaps I may add the name of the Elm as a host of the Mistletoe, for it is to be found on this tree about ten minutes' walk from my parents' home.—C. TURNER, *Highgate.*

The Prophet Flower (*Arnebia echioides*).—*Arnebia* is an Arabian name applied to a genus included in the Natural Order Boraginæ and allied to *Lithospermum*. The species *echioides*, meaning *Echium*-like, is remarkable for its singular flowers. These are of a primrose yellow colour, with a purple, almost black, spot on the lobes of the corolla. The curious thing is that the dark spot gradually disappears in a few days. The botanist Müller long ago observed that many flowers of Boraginæ in the course of individual development seem to recapitulate the evolution

THE PROPHET FLOWER (*ARNEBIA ECHIOIDES*). THE BLACK SPOTS DISAPPEAR FROM THE BLOSSOMS AFTER A FEW DAYS.

of their colours, and he instanced this theory by the blue and violet species of *Myosotis*, *Anchusa* and *Symphytum*, which gave white and rose red varieties apparently by reversion to more primitive characters. Possibly the colour change in *Arnebia echioides* is due to the same cause, but it is worth noting that it is only as the flowers age that the spots disappear. Another theory, and one which seems more probable, is that the colour change may be an adaptation to show the more intelligent insects which are the useful and, incidentally, the unpollinated flowers. The illustration clearly depicts young flowers with dark spots, and older flowers in which the spots are fading away. By reason of its peculiarity this Oriental plant is popularly known as the Prophet Flower. It is a much valued subject

for the rock garden, and although difficulty is sometimes found in increasing the stock, this may be accomplished by taking cuttings of strong roots and inserting them in sandy soil in gentle heat. It may also be increased by seeds.—C. Q.

***Saxifraga brunoniana*.**—This is a distinct and beautiful Chinese novelty which, should it prove to be perfectly hardy, will be welcomed by all lovers of choice alpine. It is also a distinct addition to its genus. Quite early in the season the plant produces numerous thread-like stolons or runners, which in the fullest sunlight assume a brilliant red colour; hence it should be grown where so good an attribute may be seen to the best advantage. Later on in June and July the plant bears a profusion of golden yellow flowers. It is readily increased by layering the runner-like shoots.—E. J.

The Golden Mohur.—While glancing through the "Answers to Correspondents" in your last issue of THE GARDEN, I noticed the reply under the heading, "The Golden Mohur." If I am not mistaken, I think "G. D.," who enquired about it, means the Gold Mohur tree, *Poinciana regia*, and not what you suggested, namely, *Bassia latifolia* and *Quercus dilatata*. The Gold Mohur is a medium-sized ornamental tree with handsome feathery foliage and beautiful reddish orange flowers. I have seen this tree, which, by the way, is classed as a timber tree, doing very well in most gardens in the United Provinces, Punjab, and also some fine, graceful specimens in zoological gardens in Bombay and Karachi.—J. C. POWELL, *Ripley.*

November Hardy Chrysanthemums.

There are a great number of Chrysanthemums for the open garden in September and October, but the hardy kinds that are the most valuable are the ones that bloom in November, when outdoor flowers are very scarce. The late season, with its many mild weeks of early winter, has been especially favourable to them, and I have never before seen the deep red *Julie Lagravère* in such perfection. Are there more of this large Pompon class? My November bloom begins—sometimes at the very end of October—with the warm white *Sœur Melanie*; then comes the larger *Cottage Pink*, formerly grown indoors under the name of *Emperor of China*. It is quite hardy in all but

exceptionally cruel weather. It is much better out of doors, both as to bloom and leaf, for the flower has its full strength of colouring, from the pale, cool pink of the outer petals to the rosy crimson of the centre. The leaves also are of stout texture and take a fine colour, agreeing with that of the centre of the flower. Nearly at the same time comes *Julie Lagravère*, with its fine red bloom and very neat foliage. I have one other of these large Pompons—not a very good doer and nearly lost—called *Soleil d'Or*. The colour is a strong orange, shading to deeper in the centre; a fine, rich-coloured thing as to the flower, but with a lanky, ungainly habit. I wish I could hear of more of this class, beginning to bloom not earlier than the first week of November.—G. JEKYLL.

December Roses.—One can often find a few odd Roses in December in two years out of three, but I think it is very rarely that one can find a tree as full of bloom as is usual in June and July. I have lately seen a weeping standard of the variety Dorothy Perkins in flower in such profusion as to remind one of the month of Roses in a garden in Hampshire. The position was not a sheltered one, as the north and east winds had full play upon the tree. I think the most notable characteristic was the very deep, rich colour of the blooms—much more intense than flowers usually come of this variety earlier in the year.—G. G.

The Columbines.—Charming alike for house and table decorations and for the embellishment of the garden during early summer, the *Aquilegia* is worthy of more extensive cultivation. The long-spurred hybrids have been so improved upon of late years that they are certainly worth some consideration now that the planting season is with us. The best results are unquestionably obtained when a whole border or large bed can be given up entirely to these plants, for then enough of each colour can be used to produce an effective display. Should the position occupied by them be required bright in spring and autumn, bulbs should be planted at the same time. There is a host of subjects to choose from for early flowers, e.g., Tulips and Narcissi, and for a display when the *Aquilegias* have passed out of flower *Liliums* (such as *tigrinum*) or *Montbretias* would answer the purpose. Although not in any way fastidious about soil, the *Aquilegia* is seen at its best in a sandy loam.—H. TURNER, *Serlby Gardens*.

Buddleia Colvillei Flowering Outdoors on Christmas Day.—It is not often that one sees *Buddleia Colvillei* flowering freely, especially at this time of the year. There is, however, a plant of this *Buddleia* growing in the open border in these gardens, carrying a quantity of blossom and flowering shoots. On Christmas Day I counted over twenty flower-spikes fully developed, while there were a large number of the other branches whose flower-buds were just showing colour. It was planted about ten years ago, and has blossomed on three previous occasions, but never so freely or so late in the season as this. The flowers are distinct from all other *Buddleias*; they resemble a rosy red *Pentstemon*. The foliage is a kind of silver grey. It is a strong-growing subject, but, unlike the others, it does not flower until it has been established for some years. Growing in the same border as a companion to the foregoing *Buddleia* is a large bush of *Eriobotrya japonica* (the Loquat) in full flower. It has occupied its present position about twelve years, but this is the first time it has blossomed. It is generally seen planted against a wall, but it makes a magnificent bush in favoured situations. It prefers a rather light, loamy soil, and is readily increased by cuttings or layers.—F. W. RICH, *The Gardens, Elfordleigh, Plympton, South Devon*.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

(Continued from page 11.)

A MODERATELY light soil is suitable for the great majority of herbaceous plants. *Astilbes*, some *Lilies*, some *Irises*, *Helleborus major*, *Meconopsis wallichiana* and *Lobelia cardinalis* are examples of those which need a strong soil to be satisfactory, and even these may be induced to be fairly happy in a light soil, rotted manure and the soil made very firm about the plants going a long way to meet their requirements. But there is so large a variety of plants to choose from that, unless for very special reasons, those plants which will not thrive in the soil of a particular garden should be left out in the furnishing of borders.

Soil Pulverisation.—Under proper treatment any soil ought to improve year by year and become better adapted for all kinds of plants. Deep cultivation is, of course, of first importance; but deep cultivation is not of itself enough, and besides turning over the soil and loosening it, all clods should be smashed, thorough pulverisation having a remarkable effect for good. It is one of the points I insist on; yet so widely different do the individuals in a squad of men understand this cultural expedient that no two

PHLOX: SHOWING DEPTH TO PLANT.

ever break the clods to the same degree of fineness, and the effect is apparent the succeeding summer in the varying qualities of the crops. In bygone days it was usual to wait two or three years for a herbaceous border to come to its best, and I have frequently seen people look as if they did not credit one's word on being told the borders here were completely furnished the first season. It is true this cannot be done unless means are taken that the plants shall grow with vigour, and vigour cannot be acquired unless the soil is not only deeply worked and knocked about till it is reduced to fine particles, but also made rich in fertilising materials.

The Best Manure.—I quite agree it is possible to make soil—by the introduction of much crude manure—too stimulating, resulting in the production of soft and rank vegetation. The manure, therefore, should have been laid up for a long enough period to have lost much of its stimulating properties, when it may be employed abundantly without any but good effect. A combination of horse and cow manure is to be preferred to either alone, and all manures should be finely comminuted and mixed thoroughly with the soil, rather than dug into it in lumps in a haphazard fashion. In addition to this principal manuring, a layer of material prepared from old

Mushroom-beds, pigeon-manure, soot, wood-ashes, old composts and surfacings of fruit borders, with perhaps a slight addition of newly slaked lime spread over the surface of the border previous to planting, enables plants to make a vigorous start. A similar dressing is also beneficial if applied to established borders which have not for any reason been otherwise manured.

Drainage, while non-essential in many gardens, in others is all-important. It is not enough to place drainage material at the bottom of borders in the expectation that surplus water will be removed in that way, for unless a proper drain is provided to carry away the water, the above expedient will simply make matters worse, inasmuch as it will be the means of drawing into it moisture from both sides without drying and warming the border itself. If the border is not more than 15 feet in width, one drain down the middle will form a sufficient water remover.

The Ideal Management of a herbaceous border, as regards the soil, is to lift the plants annually, cultivate, rearrange, and replant. Usually two or three years elapse between these overhauls, but at least some of the more aggressive plants should be lifted annually, the ground evacuated, cultivated, and the plants rearranged. It is very important that species of *Aconitum*, *Helenium*, *Helianthus*, *Aster*, *Chrysanthemum maximum*, *C. uliginosum*, *Rudbeckia*, *Senecio tanguticus* and others of a like nature should be treated thus annually. *Montbretias* also yield so much better results that it is worth while to include these among the annual plantations. There are so many good things among these that it is possible to secure a different effect by rearranging these alone in another way. I know there exists a kind of horror at the thought of intruding a spade among established herbaceous plants, the dear roots being objects of much concern lest any should be severed. May I express the conviction that nothing better could happen to the plants next to lifting and replanting. By digging deeply and carefully among them they are divested of useless roots and an improved root-run is provided, into which new roots to take the place of those removed quickly find their way, to the great benefit of the plants. Manure about twelve months old is best fitted for mixing with the soil under these conditions.

Lifting and Replanting.—On occasions when the borders are completely renewed and cultivated, I have found it much the best way, in order that planting may not be stopped by wet weather, by which operations are sometimes delayed till spring, to lift only a few yards in advance, rearrange as each short section is recultivated, and plant it up at once. It perhaps needs experience and a clear conception in one's mind of the ultimate appearance of the border as a whole to proceed on these lines, but it is the most satisfactory on the whole. The soil ought to be dry enough to permit of the plants being well firmed after planting, and the unoccupied parts also compressed so that the ground will not sink unevenly during the winter. The end of October and part of November is the period when I plant, but some things which are apt to flower early may well be left till spring, one result being a decidedly later bloom. Where *Gladioli*, *Carnations*, *Pentstemons*, *Celsias*, *Snapdragons*, *Chrysanthemums* and annuals are employed, it is incumbent that vacancies should be left for these.

Prestonkirk, N.B.

R. P. BROTHERSTON.

(To be continued.)

FRAGRANT-LEAVED TREES AND SHRUBS.

LITTLE attention is given to the small group of trees and shrubs characterised by their fragrant leaves, yet such have a peculiar charm, and in some instances perfume the air quite as much as do numerous fragrant flowers. They belong to both evergreen and deciduous species, and in almost all instances the perfume is due to the presence of essential oil secreted in small glands in the leaves. In many cases these oils are important articles of commerce, and a considerable number of persons find employment in separating them from the leaves by distillation, to be used largely for perfumery. We have, however, to consider the plants wholly in their relationship to the garden at the present time, their commercial possibilities being of secondary importance. In some cases the fragrance is easily liberated, and is very noticeable after a shower of rain or during early morning while the leaves are still covered with dew; but in other instances the perfume is only released by brushing or bruising the leaves. During the winter it is only possible, of course, to observe the fragrance of the evergreen kinds; therefore we will glance at a few of those first. Noteworthy among the number is the

Sweet Bay (*Laurus nobilis*), a fine evergreen which sometimes grows into a tree 30 feet or 40 feet high in the milder parts of the country, but is more frequently found as a large bush. Its fragrance is most apparent when the leaves are rubbed. There are two small-leaved varieties, *angustifolia* and *undulata*, which are equally fragrant. The leaves of the Bay are often used for flavouring purposes.

The Myrtle (*Myrtus communis*) is another charming, fragrant-leaved shrub, as is also its small-leaved form, *M. tarentina*. In the South-West Counties they thrive as bushes in the open ground, but in other parts they must have wall culture.

The peculiar resinous odour of many coniferous trees is usually highly appreciated by visitors to woods or plantations of Pines, Cypressess and Arbor-vitæ, for although lacking the sweetness of the Bay and Myrtle, and sometimes becoming rather pungent on close investigation, its invigorating action makes it very popular, particularly with invalids. Turning from large-growing trees to small shrubs, we find in the diminutive

Thymes worthy examples of fragrant-leaved shrubs. They are delightful when planted between the stones in unevenly paved paths, for, when passed over by ladies, the rubbing of their dresses causes sufficient agitation to set the fragrance free. The writer once saw these plants used with considerable effect in the manner

described in a Somersetshire garden. They may also be used effectively on walls. *Thymus* *Chamaedræ*, *T. citriodorus*, *T. Serpyllum* and *T. vulgaris* may all be used. Another humble plant may be found in the

Sage (*Salvia officinalis*), for its leaves are quite fragrant enough to warrant its inclusion in our group.

The Rosemary (*Rosmarinus officinalis*) is very popular on account of its delicate scent. The fragrance of the flowers is, however, more noticeable, that of the leaves not being very evident until friction has been applied. Similar remarks apply to the

Lavenders (*Lavandula spica* and *L. vera*), both of which should be included among fragrant-

Sweet Briar (*Rosa rubiginosa*), which, with the Penzance Briars, scent the air for a considerable distance, especially during early morning and after rain. In the warmer parts of the country the

Scented Verbena may be requisitioned. This, *Lippia citriodora*, has Lemon-scented leaves and forms a bush 3 feet to 6 feet high. It is hardier than is often thought, and may be grown in sheltered positions in the Southern Midlands. If placed against a wall further North, it will also succeed. The genus

Artemisia provides a number of scented-leaved shrubs, notably the Southernwood (*A. Abrotanum*), *A. arborescens*, *A. procera* and *A. tridentata*. The latter plant is also worth attention on account of its silvery leaves. In Cornwall and the Scilly Islands a number of the

Eucalypti may be grown. The most fragrant, probably, is *E. citriodora*, which, unfortunately, is also one of the most tender. Throughout most of the Southern Counties, however, *E. globulus* can be planted. Its ornamental leaves emit a perfume when rubbed. Southern Cornwall and the Scilly Islands have a wealth of fragrant-leaved material in the scented-leaved *Pelargoniums* from South Africa. In the Scilly Islands they grow luxuriantly, and when overgrowing their space they are simply chopped down and allowed to break again from the ground-line.

The Myricas or Wax Myrtles have fragrant leaves, but as a rule they are not of any great decorative value. The most ornamental is *M. asplenifolia*, a native of North America, with elegantly cut leaves. It requires moist ground and a rather cool situation.

Although these do not exhaust the list of fragrant-leaved shrubs, a sufficient number has been mentioned to direct attention to a group of plants which is usually given scanty consideration. D.

HERBACEOUS FLOWERS IN A SUSSEX GARDEN.

leaved shrubs. A more vigorous shrub is found in *Umbellularia californica*, sometimes called the Californian Laurel by reason of its leaves having a somewhat similar perfume to that of the Sweet Bay, or Bay Laurel as it is sometimes called. The various *Linderas* and *Litsæas*, though not showy shrubs as a rule, bear fragrant leaves. These, with *Laurus* and *Umbellularia*, belong to the Order Lauraceæ, an Order peculiar by reason of the large number of genera of fragrant plants it contains. In some instances, as in the Camphor, the fragrance is found throughout the wood, and the wood is distilled in order to obtain the essence. One of the most popular fragrant-leaved shrubs during the summer is the

and blue, are mingled with the nodding flowers of the Japanese Anemones, both pink and white, while the warm orange shades of the *Montbretias* lend a pleasing tone of colour in the foreground. Another garden flower used in the foreground, and one which has become exceedingly popular of late, is the Caucasian Catmint (*Nepeta Mussini*). It forms a dense prostrate tuft with numerous spikes of small lavender-blue flowers; as an edging to the flower border it has few equals. Of the *Michaelmas* Daisies, the rose pink variety *St. Egwin* and the large blue *Climax* are extensively used for colour effect, and both varieties stand out well against the wall and balustrading, which are partially clothed with wall shrubs in the background.

PLANT GROUPING FOR EFFECT.

THE accompanying illustration depicts an autumn scene in the gardens of Paxhill Park, Sussex. Herbaceous flowers are here used with telling effect. *Michaelmas* Daisies, in tones of pink, lavender

SEASONABLE NOTES ON VEGETABLES.

Trenching.—Of all details in connection with vegetable culture, none is of more importance than trenching. Apart from providing a deeper root-run in which the various kinds of vegetables will search for food—for instance, an Onion will send its roots down over two feet deep—the action of trenching warms the soil by the admission of air. Vegetables of all kinds resist drought so much better during the summer in trenched ground. There is still another advantage in trenching to note. Where the subsoil, perhaps 1 foot to 2 feet deep, is clay, or nearly so, a stiff, heavy, hard pan at the bottom of the ordinarily dug soil prevents the quick percolation of water from heavy rains. This excess of moisture immediately under the roots causes stagnation in growth.

There are various methods of trenching. Some advocate bringing the bottom soil to the surface, no matter how deep they trench. Under certain conditions this is the most effective manner of bringing the whole of the soil into an improved condition quickly. The reservation is this: If a quantity of matter like decayed vegetable refuse, old potting soil, roadside refuse, with the addition of quicklime, all mixed together, is available to cover the surface 6 inches thick, to give whatever crop may be grown a quicker start into growth than would be the case if the subsoil brought to the top was clay or a heavy, retentive soil approaching clay. If the soil is treated in this way for one or two years, then retrenched again, we get a medium that will grow almost any kind of vegetable well. If, on the other hand, such addition is not available, I advise the keeping of the surface soil in the same position, and trusting to the addition of long, strawy manure or freshly gathered leaves to the lower trenches during the operation. This method of trenching entails the use of two trenches, whereas the former needs but one. In any case, I advise that all stiff soil be broken up to the depth of 3 feet, and in all cases deeply dig the bottom of each trench, leaving this in a rough state. This method of trenching may seem a laborious matter, but it is an excellent plan, and when once well done it will last a long time and so improve the conditions for vegetable growth that it is time well spent.

Exhibition Onions.—The first or second week in January is a good time to sow the seed. There is no better variety than Ailsa Craig from a good strain. The seed should be either home saved or obtained from a reliable seedsman. This variety possesses all the attributes of a good Onion—size, shape, early maturity, long keeping, and a vigorous constitution. The ordinary Geranium cutting boxes, 4 inches deep, answer well for sowing. Place a few crocks at the bottom, covering these with rough leaves, and fill the boxes to within half an inch of the top firmly with a compost of loam, leaf-mould, decayed Mushroom-bed manure, and sufficient sharp sand to make the whole gritty. Select large and plump seeds,

sowing them regularly an inch or so apart. Cover the seeds lightly, yet firmly, with similar compost finely sifted. If the soil is not sufficiently moist, give a gentle watering and place the boxes in a vinery or Peach-house just started, where the temperature is not less than 55° or 60°. Directly the plants appear above the surface, the boxes should be placed in a light position close to the glass, to prevent the plants becoming drawn.

Broad Beans.—No time should be lost in making a sowing of Windsor or Longpod on a sheltered border or in a favourable position in the open. Well fork over the site, leaving it light below and thus drier. In a trench, 4 inches deep, spread some light compost on which to place the double row of Beans angle-wise, covering them lightly with the same compost, to be increased as the plants push through the soil, which not only aids growth, but protects them also from birds, slugs and bad weather.

Seakale.—When the roots are lifted for forcing, the next season's crop should be considered, taking care of the small roots about six inches long,

Even in the depth of winter it retains its beauty, spreading like a silvery carpet close to the ground and making a pleasing contrast with dark green Ivy if the latter is grown in the background. There are other Santolinas of hoary appearance, such as *S. incana* and *S. squarrosa*, the former a small, silvery shrub suitable for the rock garden, and the latter a variety of the Lavender Cotton well suited for carpeting banks. The *Cerastium*, common Lavender and garden Pinks are other grey-leaved plants that are appreciated for their winter effects, while in summer we have many others, of which *Cineraria maritima*, *Antennarias* and *Stachys lanata* are perhaps the best known.

TWO INTERESTING BELL-FLOWERS.

CAMPANULA EXCISA AND C. ZOYSII.

I THINK the reason why the rare *Campanula excisa* so universally fails in cultivation is that it gets

THE GREY-LEAVED LAVENDER COTTON (*SANTOLINA CHAMÆCYPARISSUS*) IN MIDWINTER.

of the thickness of a cedar pencil. Tie them in bundles and place them in sandy soil in quite a cool place. Put fresh roots as required—a few at a time is best—in the various places for forcing. Nowhere is better than in a Mushroom-house, where blanching is perfectly done in the dark, moist atmosphere, and where a genial heat is maintained for the benefit of the Mushrooms. Cover the crowns with clean, freshly gathered leaves, which aids growth and ensures perfect blanching. If no Mushroom-house exists, a deep box, placed on the top of the brickwork over the boiler in the stovehole will suffice, if the crowns are covered with leaves, kept moist; or an inverted flower-pot over another with the roots in, stood on the hot-water pipes in the greenhouse, will suffice.

Swanmore Park, Hants.

E. MOLYNEUX.

SILVERY LEAVED PLANTS.

ONE of the most beautiful of all garden plants with silvery grey foliage is the Lavender Cotton, botanically known as *Santolina Chamæcyparissus*.

so pitilessly cut to pieces by propagators that its poor little relics are ultimately unable to make headway. Properly rooted, however, in sound masses, I believe there should not be any difficulty at all, whether in sun or shade, about growing *C. excisa*, so long as it is remembered that hitherto (one must never be prophetic: *C. alpestris* has weakened to lime, so why not *C. excisa*?) *C. excisa* remains *ex hypothesi* firmly opposed to any suspicion of lime, and also, as I think, to any heaviness of soil. For the first time I studied this plant last year *in situ*; it is very clearly a perfectly easy and robust species. For, though extremely rare, it is also extremely common and pervasive; confined to the northern and southern sides of Monte Rosa (with one outlying station, at least, in the Engadine), it is there universal, taking the place of *C. pusilla*, from the river-beds close on Macugnaga, through the thinner Larch slopes, up to the shingles by the Belvedere Glacier, where it forms masses of colour a yard and more across. Here it is evidently in its fullest glory; thus

growing, tube-flowered in open earth, it grows ample and profuse, in wide tussocks, from the pure granitic sand among lumps and boulders of granite. It is finer and wirier and more graceful than *C. pusilla*; at the same time, not so far removed in general effect but for the more violet note of the blossoms and their extraordinary little punched-out hole at the base of the corolla segments. The blossoms, however, vary in form; those usually (and so rarely) seen in cultivation are a trifle starved looking and mean, but search among the plant at its happiest soon produces one variety with splendid opulent blossoms, plump and comely in outline. There are pale variations, too, and a pure albino. To this I was fully directed; I duly found all the points of direction, found the spot—found everything except the white *Campanula*. Now, soundly rooted, I see *C. excisa* sprouting freely everywhere; in one garden I know it now has to be “hyked” up by handfuls, like a weed, and cast away. There it is growing in a very rich mixture of leaf-mould and coarse sand, with a perpetual flow of underground water. With me, on the contrary, it has not seemed to enjoy the sandy part of the water-bed especially made for its needs, but is thriving very freely in a drier and lime-fraught portion where I cannot remember that it was ever put. And finally, it has a habit of dying down and then coming up again a few weeks later quite unperturbed by the alarm it has caused to its cultivator, who is quite prepared for its winter disappearance underground, but is rendered unhappy by such unexpected games of “Peep-bo.”

Campanula Zoysii.—Why are cultivators, in THE GARDEN or elsewhere, warned to be afraid of this easy and hearty little species? One might as well be nervous about *C. pusilla*! A possible reason is that gardeners oftener fail with *C. Zoysii* because, being so much rarer, it is subdivided beyond its strength by nurserymen, and sent out in no fit condition to battle with a slug-ruled world. Otherwise, *C. Zoysii* is a species no less hardy and hearty than *C. pusilla*, though incomparably rarer. Many enthusiasts who have successfully grown *Campanula Zoysii* cherish it above all others. It is a limestone species of the Eastern Alps (Karawanken, &c.), where it not only occupies the high, hard chinks, like *C. Raineri*, but also gives notice of its adaptable temper by descending far down into the river shingles, where it forms immense masses more than a yard across, very unlike the tastes or developments of *C. Raineri*. There, in stony sand, it waxes hugely, but seems to flower so late that on August 24 of last year hardly a bud was open. Now, in my garden, collected plants of *C. Zoysii* (small pot plants in spring) are 6 inches tall and even more across, with sheaves of their lovely little odd puckered flowers, blue and whitish, like stoppered bottles. They are growing in light, rich loam, plentifully mixed with lime rubble, and with water percolating beneath; and here it

is quite evident they mean to wax fat and spread like *C. pusilla*, without any question of difficulty or care—except in connection with slugs, which greedily devour them. *C. Zoysii* does not seem to vary much in colour, except in the case of the wonderful pure white albino, which I purchased for vast sums from its possessor, and which has rewarded me, accordingly, with flowers of a much richer blue than the type. REGINALD FARRER.

A BEAUTIFUL HARDY PRIMULA.

PRIMULA PULVERULENTA MRS. BERKELEY.

This variety is sure to be a warm favourite when better known. The type, *Primula pulverulenta*,

PRIMULA PULVERULENTA MRS. BERKELEY GROWN FROM SEED.

a fine sturdy species with showy ruby crimson flowers, and flower-stems thickly coated with a white farina, is too well known to need further description. The variety Mrs. Berkeley, however, has flowers of a soft rosy orange shade with a deeply coloured eye, and they are borne in towering heads tier upon tier, as is the case with the type. Happily, this variety comes true from seed, and if the seedlings are planted out in a suitable niche in the rock garden, as depicted in the illustration, a pleasing show of bloom is assured from the middle of May until midsummer or even later. Seed should be sown next month in gentle heat. A half-shady position and a retentive loamy soil suit the requirements of this variety admirably.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES.

(Continued from page 5.)

Rayon d'Or (Pernet-Ducher, 1910).—This striking yellow (almost garishly so) Rose was a very great break, and it has proved of very material benefit to the hybridist, and therefore all Rose-lovers are very much indebted to its raiser. Its colour is unique, and hits one in the eye with a certainty that brooks no denial of your immediate attention. But for all that—in fact, on account of that, possibly—Rayon d'Or does not appeal particularly to me. A fairly robust grower, quite mildew-proof; its foliage only succumbs to that worst of all Rose pests, black spot, to which it seems particularly prone. Whether the black spot is also answerable for its other bad habit I do not know, but it is very unsightly, namely, the dying back of wood of the season's growth. I am prepared to forgive it its thorns, which are formidable. I think everyone should have a plant of it in his garden in bush form, but I cannot recommend it as a standard or as a bedding Rose. It has had and will continue to have an influence on many future generations of new Roses, and one can only hope that it will transmit its good points, which are undeniable, to its offspring.

Reine Marie d'Italie (H.T., Bernaix, 1910).—There is not much shape in this variety, but the colour is at times quite good—a deep ochre yellow that stands well. It is strongly Tea-scented, and its habit of growth is Tea-like. It is quite free-flowering enough for a bedding Rose, and my couple of plants have arrested my attention on more than one occasion during the season. It might be tried instead of Lady Hillingdon in the Midlands and the North as a yellow bedder.

Rose du Barri (B. R. Cant and Sons, 1911).—This is quite happily named; it is a very free-flowering bedding Rose of about three rows of petals of a charming rose du Barri pink. It has

a strong scent, and is very useful cut in long sprays for the house, as many of the flowers open at the same time and last well when cut. Almost mildew-proof and a good grower.

Seabird (Hugh Dickson, 1913).—This has been well exhibited on many occasions by the raisers during the last two seasons, and was distributed by them last autumn. Its small but well-formed flowers are of a delightful primrose shade of yellow—a colour that is badly wanted—and, if it will stand, this Rose will speedily be in request. The plants are of good shape, of the desired free-branching habit, producing their flowers freely on good, erect growths. I am looking forward to flowering it here this year.

Sunburst (Pernet-Ducher, 1912).—"Variable," I am afraid, must be the decision with regard to this Rose. The majority of the flowers I had last year lacked the true Sunburst colour, and looked to have had to burst through a very heavy raincloud and suffered badly in the process. Still, I have had some beautiful coloured buds that easily beat Lady Hillingdon or any other Rose for purity of colour, but they were few and far between. The pretty theory about stopping the first flowers has not worked out of doors with me; it may very well do so under glass. I shall continue to grow it for the sake of the one or two "righteous" flowers, but a bed I saw of it in the autumn was distinctly disappointing and had to play second fiddle to Lady Hillingdon.

Theresa (Alex. Dickson and Sons, 1909).—Very charming in the bud and early stages and lasting well to the end. This semi-double Rose was much admired, both in the garden and in the house. Its rather unusual colouring appeals to many. Deep orange pink with carmine markings on the outside petals in the bud form, it opens out into a pretty semi-double silvery pink with distinct carmine veinings. Very free-flowering, sweetly scented, not particularly subject to mildew, and a good strong grower. It is a very delightful and at the same time useful Rose. Tea scented.

Verna Mackay (Alex. Dickson and Sons, 1912).—Such has been the demand for this delightful Rose that I understand the raisers can supply no more plants this season. I am not surprised. Everyone admired it here; its exquisite shape and delightful colouring made it at once one of the most beautiful buttonhole Roses there is. It can be best described as a yellow Carine. All those who like Roses for wearing on the dress or in the buttonhole cannot do better than grow these two Roses if they can get them. Good free habit, almost lemon colour, nearly mildew-proof, it is very difficult to find a fault with Verna Mackay.

Viscount Carlow (Alex. Dickson and Sons, 1910).—One would venture to think there was a good deal of the old G. Nabonnand blood in this Rose. It has the same shell-like petal, but is a deeper colour and a much stronger grower, with fine dark foliage which, alas! is not mildew-proof. It was splendid in the autumn and very free-flowering all the season.

Viscountess Enfield (Pernet-Ducher, 1910).—If this Rose was only a better grower it would be quite useful. The flowers are at times very pretty—a good coppery rose—but they are small and not very lasting.

Willowmere (Pernet-Ducher, 1913).—I think this is the pick of the Pernet-Ducher seedlings. It is a delightful, delicate shade of coppery pink. I have not grown it, but have had some very beautiful flowers of it sent me. I intend to try it out of doors this year.

Southampton. HERBERT E. MOLYNEUX.

NEW ROSE IONA HERDMAN.

VISITORS to the National Rose Society's Provincial Show at Gloucester in July last will remember this beautiful Rose, for it was the most striking of all the novelties, and was deservedly awarded the society's gold medal. It is a decorative variety after the colour of Old Gold, but of greater depth and intensity. It was shown in a basket, depicted in the illustration, and came in for general admiration. It is one of the sterling novelties raised by Messrs. S. McGredy and Son

CULTURAL HINTS ON NEW AND RARE PLANTS.

TREES AND SHRUBS.

Carpenteria californica is a Californian shrub closely allied to the Mock Oranges, though less hardy. Thriving well in the Southern Counties, it is also sometimes found in good condition in the Midlands, while it has been noted in good health as far North as Perthshire growing in a sheltered position on a rockery. Its evergreen leaves are 4 inches or 5 inches long and scarcely more than an inch wide, while its white flowers, which are produced in clusters, are from 2 inches to 3 inches across. Loamy soil, with a little leaf-mould or peat, and a position sheltered from cold winds are conducive to success.

thrive against a wall with a south or west aspect. Light loamy soil forms the most suitable rooting medium, and a little peat or leaf-mould mixed with the soil at planting-time encourages the formation of roots. Seeds form the most satisfactory means of increase.

Cotoneaster applanata is a new species from China, which promises to rank with the best of the Himalayan species previously grown. Of free growth, it forms long, rather slender branches, with dark green ovate leaves. Its chief attraction lies in its fruits, which are bright red in colour and produced with remarkable freedom, hanging on the plants throughout autumn and early winter. Planted in a shrubbery or on the open lawn, it thrives excellently in soil of a loamy nature, and may be readily propagated by means of seeds or by cuttings of half-ripe shoots.

THE NEW GOLD MEDAL ROSE 'IONA HERDMAN.'

Lycium pallidum.—This is perhaps the most interesting shrub in a genus of which the common Tea Tree (*L. chinense*) is the best-known representative. A native of Mexico, it forms a loose bush 3 feet to 5 feet high, with glaucous leaves and rather large, tubular, yellowish green flowers, which are succeeded by orange scarlet fruits. It is increased by seeds and grows well in ordinary garden soil, but must be placed in a permanent position while quite small.

Notospartium Carmichaeliae.—This New Zealand shrub has been known in botanical collections for many years, but it is rarely met with in private gardens, although an exceedingly beautiful plant when the Rush-like branches are wreathed, during June, with pretty pink, Pea-shaped flowers. It is only suitable for the warmer parts of the country, but there are numerous places where it would

Fraxinus Mariesii belongs to the Flowering Ashes, of which the best-known example is the European *F. Ornus*. *F. Mariesii* is a small tree, native of China, and is conspicuous by reason of its dark green ample foliage and its large panicles of white flowers, which appear in May. It is essentially a tree for a prominent position on the lawn, and should only be planted where really good and fairly moist loamy soil can be provided. It is most satisfactory when grown from seeds, but is sometimes grafted upon stocks of *F. Ornus*.

Eueryphia cordifolia.—This Chilean shrub differs from the better-known *E. pinnatifolia* by having simple oblong leaves. Its white flowers are very pretty, and quite as ornamental as those of the commoner species. Although it thrives in the open ground in some parts of Surrey, it is really a shrub for the South-West Counties, and the most

satisfactory results are obtained from it in Devonshire and Cornish gardens. Plant in warm, well-drained loamy soil, and place a little peat or leaf-mould about the roots at planting-time. [Propagate by seeds.]

Aristolochia moupinensis.—A near relative of the common Dutchman's Pipe (*A. Siphon*), this Chinese species promises to become quite as useful as that widely-grown plant. A vigorous grower, it forms slender branches 10 feet to 15 feet in length in a single season, and bears ornamental green foliage and curiously shaped yellowish or greenish yellow flowers with purple marks. It is well adapted for planting against trellises or on pergolas, while it may also be employed for covering a large bush. Rich loamy soil forms the best rooting medium.

Rubus bambusarum.—The beauty of this Chinese *Rubus* lies in its long, slender branches and finely lobed leaves, for the combination makes it an exceedingly graceful plant, eminently suited for planting against a trellis or pergola, while it has also attractions when grown as a pillar plant in the open. Like other kinds of *Rubus*, it succeeds quite well in ordinary garden soil, and particularly in that of a loamy nature. A few of the older branches should be thinned out each year, in order to keep the plant within bounds and to prevent a heavy appearance.

EPACRIS FOR WINTER FLOWERS.

SOME of the species of *Epacris*, and many of the garden varieties that have been obtained therefrom, may be had in flower during the winter months, and they are very useful for the decoration of the greenhouse at this season. What is more, they retain their beauty for a considerable time, and their long shoots, wreathed with flowers, are very useful for table decoration when arranged in small vases. In the present-day rush the merits of many subjects that are of somewhat slow growth are apt to be overlooked, and this is, no doubt the cause of the comparative neglect of hard-wooded plants in general, for many of them are really of great beauty. That this class of plants only need a stimulus of some kind to bring them into the light of popularity was well shown last year at the Royal Horticultural Hall, when a collection of Heaths, representing the wild flora of the neighbourhood of Caledon, Cape Colony, was surrounded by admirers during the greater part of the day. To return to the forms of *Epacris*, it may be pointed out that they vary in colour from pure white to bright rosy red, some of the more delicate shades of pink being especially pleasing. The pure white *Epacris onosmaeflora* flore plena attracts by reason of its pretty double, rosette-like blossoms, while the brightly-coloured *E. longiflora* carries the display on into the summer months.

H. P.

SEASONABLE NOTES ON CARNATIONS.

NOW is the time that Perpetuals are, as a rule, propagated, and though they are generally facile things to root, there are some growers who experience a difficulty in getting up their yearly stock from cuttings.

The only time cuttings have failed here has been when the attendant has allowed them to flag, and, worst of all, when flagging has been a result of dryness. I am so particular about the cuttings being always moist that as soon as they are detached

that plants from cuttings are superior in every way. I have also grown plants from eyes, but only of new sorts, and, of course, a short piece of stem with its two leaves and its one break is always a long way in the rear of the cutting. The only excuse one can give for the "eye" is that it is detached from the lower portion of a cutting, that it increases the number of plants of a scarce variety, and therefore is a gain. Another way of increasing new varieties is to use the top of the rooted cutting, when it is stopped, as another cutting. Moisture has a very pronounced effect in the production of roots in young Carnations; consequently, after the cuttings have been transferred from the propagating medium to small pots, the soil should be

kept continually in a moist condition. This treatment will ensure a rapid ramification of the soil with roots and the transference of the plants to larger pots—another part of their early treatment which on no account should be delayed a day longer than can be helped.

Just when to stop the plants has to be decided by the condition of each. I am strongly of the opinion that early stopping is a mistake, and I like the plant to be well established at the roots and with a growth at an average of eighteen leaves before stopping; but of this I hope to have more to say later, because now I wish to name a few varieties with which the beginner ought to furnish himself, or herself, for one of the most enthusiastic growers I know is a lady who does everything herself for her pets.

Good Varieties.—Some I rather hesitate to name on account of idiosyncrasies which a grower in a small way would find wearisome. Such is *Carola*, than which *Triumph*, though not so expansive, gives much better results, and *Baroness de Brien*, rather shy to bloom and asking for high cultivation. Some, of course, do well with one and not so well with another, and there are good and less good forms of varieties, which the grower will be sure to notice occurs in his own stock, for the Perpetual is essentially sportive alike in form and colour. These, then, and *Mary Allwood*, *May Day*, *Empire Day*, *White Wonder* or *White Perpetual*, *Winsor*, *Triumph*, *Countess of Lathom*, *Mikado*, *Fairmount*, *St. Nicholas*, *Rose Dorée* and the *New*

Champion and *Gorgeous*, and, I think, though superseded by *Empire Day* and *Lady Northcliffe*, the very free *Mrs. F. Burnett* should be added.

Prestonkirk, N.B.

R. P. BROTHERSTON.

CARNATION SALMON KING.

WHEN better known this is sure to be one of the most popular of Perpetual-flowering Carnations. It is an effective and beautiful variety, with bright salmon rose flowers that are freely borne even in the depth of winter. The blooms are full and travel well, while they are also fragrant and the calyx does not split. In October last this variety gained the distinction of an award of merit from the Royal Horticultural Society when shown by Messrs. Stuart Low and Co.

THE PERPETUAL-FLOWERING CARNATION SALMON KING.

from the plants they are moistened and kept so, and the rooting medium, after their insertion, is kept wet till roots have been emitted. In a stove propagating-pit cuttings root in from one to three weeks; in a cooler structure, in three to four weeks. Sand is the universal rooting medium, but this is by no means essential, and acting on experience I gained years ago with *Germania*, thousands of which I rooted in spring, the cuttings being inserted in a bed of firm soil and protected by means of shallow bottomless boxes covered with glass, I rooted cuttings of Perpetuals in November last in much the same way and in soil.

Layering is another and certain method of propagation. I am, however, of opinion, from the behaviour of the few I have grown from layers,

GARDENING FOR BEGINNERS.

HOW TO PLAN AND CROP A GARDEN WITH VEGETABLES.

IN dealing with this subject I am presuming that the cultivator has not had much experience. A cultivator of flowers or fruits, as well as of vegetables, is obliged to gradually obtain experience if he is relying solely on that gained year by year from the actual cultivation of the various crops. There is sure to be some loss of good pro-

well as partially overshadowed. Fig. B shows a plan of a garden very suitable for a quite open position—one, for instance, surrounded by a low hedge or fence constructed of wood.

The Treatment of the Soil.—The soil must not be dug or trampled on while it is in a very wet state. Quarters that were dug in the early part of the autumn, or trenched later, should be left undisturbed for a time, until the weather generally has had a beneficial effect on it. In the meantime, however, the cultivator may proceed with the work of marking out the various plots, so that he will have all ready for the seeds and plants in due course. Where soils of a light nature obtain, much progress may be made during open weather with the actual work of preparing the ground for the crops that are to be dealt with first.

Fig. A.—No. 1 denotes the garden frame placed in the warmest corner of the garden. In a frame of this kind many seeds may be sown, and the resultant plants will be available for putting out much sooner than those raised in the open border. A frame is more necessary in a garden the soil of which is clayey; for this reason, while the clayey, cold soil is mellowing and getting warmer, the plants of the earliest kinds of vegetables are being grown on, so that very little time is lost, and, of course, there is no necessity for untimely working of such soils, which, if properly treated, generally yield very heavy crops of high-class produce.

In the frame, Cauliflowers, Brussels Sprouts, Celery, Peas, Leeks and Onions may be raised. In borders Nos. 2 and 3, early Carrots, Turnips, Potatoes and Peas may be grown; in Nos. 4 and 5, early salads. Tall-growing kinds, such as Runner Beans, Peas and Broad Beans, should be cultivated in Nos. 6, 7 and 8; in No. 9, early and second-early Potatoes, where late ones are not grown in the garden. Onions, Carrots, Beet and Parsnips should be grown in No. 10, salads and Parsley in summer in Nos. 11 and 12, Celery in

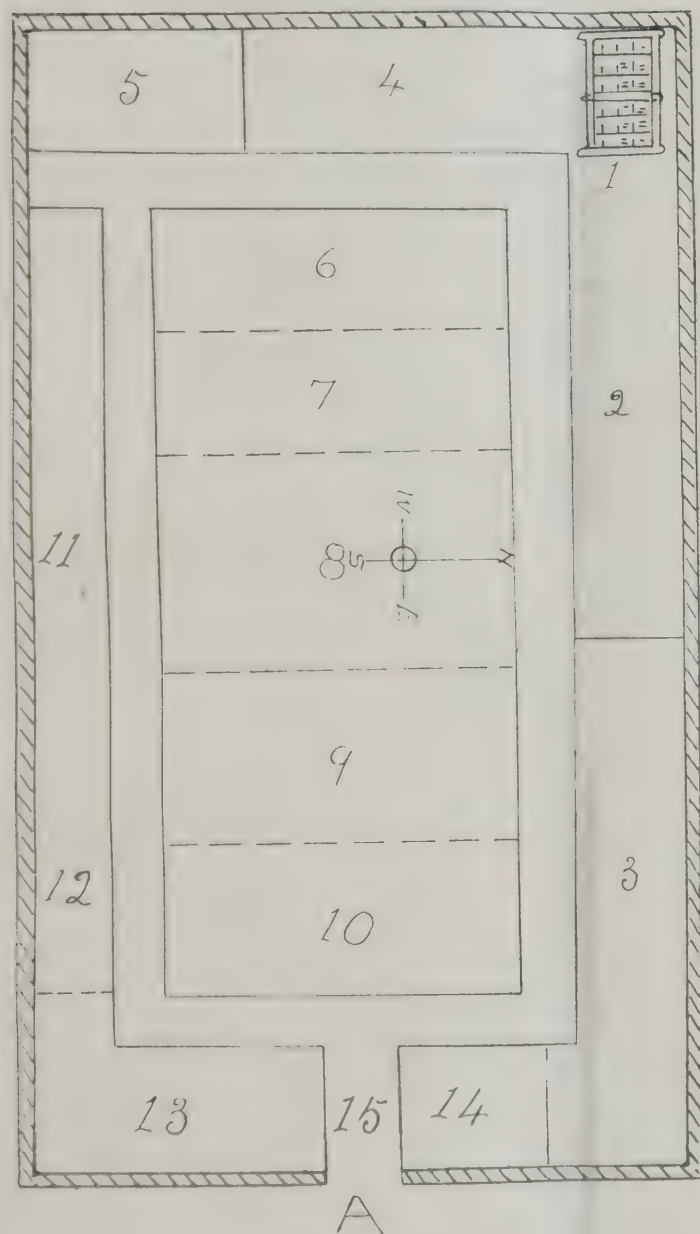

No. 13, and herbs in No. 14. Near the frame, seed-beds, in which winter greens may be raised, should be formed. No. 15 denotes the paths.

Fig. B.—In this garden, the form of which is typical of many hundreds in the country, there is only one central path, the various beds being laid out to right and left of it. Nos. 1, 2 and 3 are beds for early Potatoes, Turnips and Carrots; Nos. 4 and 5, beds for early Peas, Dwarf Beans, Broad Beans and Spinach; No. 6 would prove valuable as a warm corner in which to raise early seedlings for transplanting later; No. 7, Celery; No. 8, late Potatoes; No. 9, main crops of Onions, Carrots, Parsnips and Beet; No. 10, main crops of Broad and Runner Beans and Peas.

Of course, these would follow the planting of the winter greens, but the cultivator must get the young plants ready to fill vacancies as the first crops are cleared off the ground. G. G.

A BEAUTIFUL PLANT FOR HEDGES.

COTONEASTER SIMONSII makes a very beautiful and satisfactory hedge for a garden, and a well-trained hedge adds considerably to the good appearance of the garden. The plant referred to grows rapidly, almost as quickly as the Privet; but it does not dry up the soil to the same extent as the latter. The leaves measure about an inch by half an inch, are dark green in colour, and remain on the plants throughout mild winters. Then there are the lovely orange and red coloured berries, which add to the beauty of the fence. In a few years' time the hedge, if well cared for, gets thick and compact—much firmer than does one of Privet. In mild weather the Cotoneaster may be planted any time till as late as March. The soil, after being trenched about eighteen inches deep, will form a suitable rooting medium without the addition of manures. The latter may be lightly pointed in after an interval of five years, to afford a stimulant to the plants, as they may need it then. The aim should be to secure a short-jointed, dense growth. Put the plants in zigzag form a foot apart. B.

PLAN OF AN ENCLOSED GARDEN WITH CENTRAL BEDS.

duce and much disappointment; but through the pages of *THE GARDEN* a reader may greatly lessen that loss, if not entirely avoid all loss, by following the hints given herein in reference to the growing of the principal kinds of vegetables during the year 1914.

Now, some gardens—especially in suburban and town areas—are much enclosed by high, or fairly high, buildings. In such circumstances the owner or cultivator must avoid as much as possible having his more important crops near the other boundaries, as, owing to the partial shade, the growth of the plants will be somewhat adversely affected. The nearer the centre of the garden they are, the more sturdy and satisfactory will the growth be. Fig. A shows how a garden ought to be planned for a position such as the one referred to. Of course, it is suitable for any position, open as

PLAN OF A KITCHEN GARDEN FOR AN OPEN POSITION.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Fruit-Houses.

Early Peaches.—Peach trees in the early house will now be swelling their buds, and, before the flowers are open, the house should be carefully fumigated with XL All Vaporising Compound to destroy any green or black fly which may be present. During the flowering period the atmosphere should be kept on the dry side and a night temperature of 50° maintained. Admit air whenever the external conditions are favourable. The flowers when open should be lightly touched at midday with a rabbit's tail or a bunch of soft feathers tied on a light Bamboo cane. As soon as the flowers are set, the trees may be lightly syringed twice daily, but avoid a stagnant atmosphere.

Figs in Pots.—Trees which were placed in heat at the beginning of December will now be showing fruit. A moist atmosphere and an almost constant circulation of air should be maintained. A temperature of 50° at night will be quite high enough till the fruits are well advanced. Fig trees planted in restricted borders may be started now. Their chief requirements are a moist atmosphere, plenty of water at the roots, providing the borders are well drained, and a temperature of 50° to 55° at night.

Plants Under Glass.

Winter-Flowering Begonias.—Plants of the Gloire de Lorraine type which have finished flowering should be cut over now, removing all the flower-spikes without cutting the plants too hard. If kept in a temperature of 65° and frequently syringed, good, strong cuttings will soon be available for next season's supply.

Carnations.—Autumn-struck plants of Souvenir de la Malmaison should be freely ventilated in order to keep them stocky. A temperature of 45° at night will be high enough. Old plants which are well established and the pots full of roots may have weekly applications of Clay's Manure.

Cinerarias.—Plants which have been grown in cold pits may be placed in a cool house now. Fumigate the plants at once and give frequent applications of manure-water.

The Flower Garden.

Sweet Peas should be sown now for planting out in April. Three-inch pots may be used, placing only a few seeds in each pot. They may be stood in gentle heat until the plants are through the surface, when they may be removed to a cold pit and gradually hardened. Protection from mice is necessary until the plants are through the surface.

Sowing Seeds.—Now is the time to sow seeds of certain bedding plants, such as tuberous-rooted Begonias, *Verbena venosa* and *Pentstemons*. All these should be placed in a temperature of 65° to cause them to germinate as quickly as possible. As soon as the seedlings are large enough to handle, they should be pricked off in small pots or shallow boxes. *Delphiniums* may also be sown now for flowering in the autumn.

Chrysanthemums.—Plants which were lifted in the autumn and placed in cold pits are now producing plenty of shoots suitable for cuttings. These should be inserted in sandy soil before they become drawn, and placed in a close, cool pit.

The Hardy Fruit Garden.

Pruning.—All trees on north walls should be pruned and nailed while mild weather lasts. The soil should then be lightly forked over and left to the influence of the weather. In planting fruit trees on north walls, the border should be thoroughly trenched and a quantity of broken bricks and old lime rubble mixed with the soil in order to keep it in a porous condition. The pruning and regulating of orchard trees should be taken in hand as soon as possible. In the case of young trees, all branches that cross each other should be removed in order to admit light and air to all parts of the tree. If this is neglected while they are young, it is a difficult matter to restore them to a respectable shape afterwards. The leading shoots should be cut well back each season.

so that when the trees have grown to a fair size each branch may be furnished with fruiting spurs from top to bottom.

The Kitchen Garden.

Tomatoes.—Seeds should be sown at once and placed in a temperature of 70°. When the seedlings are well through the surface, the pans should be placed quite close to the roof glass in a temperature of 60°.

Cucumber Seeds should also be sown in small pots and placed on a hot-bed within 18 inches of the roof glass. Protect the seeds from mice and plant out the seedlings as soon as they have made their second rough leaf.

Rhubarb Roots may be lifted and placed in heat. Any place will suit them so long as sufficient heat can be produced to start them into growth. The Mushroom-house or a heated pit will suit them well.

Mushrooms.—In order to keep up a regular supply of Mushrooms, a bed should be made up every three or four weeks. Let the horse-manure be collected and thoroughly prepared before the beds are made up. If placed in an open shed and turned every second day for a fortnight, it should be ready to remove to the bed. After a few days the material may be rammed tightly together, and when the temperature is steady at 80° the spawn may be inserted 2 inches under the surface.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—Where Onions are required for exhibition purposes, now is a suitable time to sow the seeds. Use shallow boxes filled with moderately rich soil, which should be well watered before sowing, and place in a cool greenhouse or vinery in a temperature of from 45° to 50°. No water will be required until the seeds germinate, after which they should be placed on a shelf as near the glass as possible and watered carefully, as they are very liable to damp at this season.

Cauliflowers.—A small sowing of an early variety of Cauliflower may now be made. I have found Sutton's First Crop and Dobbie's Earliest of All useful for this sowing. Sow the seed thinly and keep the young plants near the glass, and the greatest possible care will have to be taken to prevent damping.

Tomatoes.—Where early Tomatoes are required, a few seeds may now be placed singly in a pot or pan and stood in a house of about 60°. If the seeds are new, they will germinate in a few days, so that they will have to be carefully looked after, otherwise the seedlings will become drawn. Prick off into small pots when they show the third leaf, keep the soil rather loose, and place them on a shelf near the glass.

Seakale not intended to be lifted and forced may now be covered with pots and protected with stable manure. It is generally said to be of a much finer flavour treated in this way than when lifted and forced.

Brussels Sprouts.—When the Sprouts have been picked and the tops used as a vegetable, and one has some difficulty in giving a change, I find an excellent dish can be made from the cores of the stalks, which used to be thrown on the rubbish-heap. It is prepared by splitting up the stalk and taking out the core. Boil the cores in hot water with a little soda, as one would do with Cabbage, and serve with butter. The *chef* calls it *purée de Choux de Bruxelles*. Those who have not made use of these should most certainly give them a trial. They make a simply delicious dish.

Hardy Fruits.

Strawberries.—Plantations of Strawberries that are rather old and have to bear a crop of fruit for another season will be greatly benefited by a liberal application of strawy farmyard manure. This may be given now. Should the weather permit, by the time the fruit appears the straw will be washed clean, and no other protection will be required.

The Flower Garden.

Lily of the Valley.—Established beds will be greatly benefited by a liberal top-dressing of spent Mushroom-beds, which is about the only way one can feed them, and, on the whole, will be all that is required. At this particular season the great evil to be guarded against is damp. This applies more particularly to occupants of cold frames, such as Carnations, *Pentstemons* and Pansies, which should only have sufficient water to keep them alive, with plenty of air on all favourable occasions. Examine roots of Dahlias and tuberous Begonias, and any that may show the slightest sign of shrivelling or rotting must be attended to. Should the variety be extra fine, place the plants in pots or boxes of soil or sand. Keep all pots or boxes of cuttings on the dry side.

Fruits Under Glass.

Peaches.—Where a supply of early Peaches is required on established trees, a house may now be closed and brought on slowly. Admit air freely on fine days and apply no artificial heat for at least a fortnight; then only on very cold nights. Examine the borders to see that they are not suffering from a lack of moisture. As soon as the flowers show signs of opening, fumigate the house, as I generally find that if fumigated at this stage they are not so liable to be attacked by green fly later.

Grapes.—Where pot Vines are not grown and Grapes are expected fairly early in the season, close down a house at once, and, as in the case of Peaches, apply no fire-heat for at least a fortnight. The temperature should not exceed 45° by night, with a rise of 10° by day. As soon as the buds show signs of swelling, a slight syringing with tepid water may be given twice a day to assist the buds to move, and great care will be necessary in admitting air at this stage.

Strawberries.—A fresh batch of Strawberries may be taken into heat. Force very gently at first, and as the plants begin to move they may be given a higher temperature. As Strawberries are gross feeders, they should be top-dressed with a little loam and artificial manure, which will be sufficient until the fruit has set.

Figs.—The first crop of Figs will now be on the move, and should have an abundant supply of water at the roots. Syringe the trees freely, as it is of the utmost importance to keep the shoots and leaves absolutely clean, otherwise scale will very soon make its appearance.

Plants Under Glass.

Begonias are again coming into favour as bedding plants, and deservedly so, as under liberal treatment I know of no plant that will give more satisfaction. To increase the stock a sowing should be made at once, and if grown on steadily they will flower next August. Sow in well-drained, shallow pans with some coarse material over the crocks and some fine sandy loam on the surface. Water it slightly with tepid water. Sow the seed carefully, scarcely cover with a little sand, and place in a temperature of between 60° and 70°. Germination is, as a rule, very slow. Thin out the seedlings as soon as they can be handled and keep in a growing temperature for some time.

Sweet Peas.—Those that were sown in the autumn and intended for blooming indoors will be growing freely, and may now be potted into their flowering pots. It is of the utmost importance to ensure a sturdy growth that they should be kept as near the glass as possible and avoid coddling. Train each shoot up singly. Soil may now be prepared for sowing the main batch towards the end of the month.

Celosia.—Seed may now be sown of that elegant plant *Celosia pyramidalis*, which is so deservedly popular for furnishing greenhouses.

Verbena venosa.—Where this lovely *Verbena* does not stand the winter without protection, it is a good plan to make a sowing now. It is, however, one of the most tiresome things to germinate I know. I have tried it in every possible way, with various results. But the plan I now adopt is to steep the seed in tepid water for a few hours before sowing. So far, this is my most successful method. After all, it is really worth a little extra trouble.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

THE IDEAL ORCHARD FOR SMALL HOUSES.

(Continued from Vol. LXXVII., page 627.)

THE planting of the standard trees having now been completed, the next important thing we have to do is to prune the trees. This, although a simple matter, is one which puzzles the amateur fruit-grower more than perhaps any other item of work he has to attend to. In the case of young trees such as we are considering, there is very little pruning to do. What there is consists in cutting back the whole of the young shoots of last year's growth by one-half their length, being careful to cut each shoot back to an outside bud (that is to say, a bud on the outside of the branch, and not on the inside), the reason for this being that the new shoots issuing from such buds will grow laterally and thus help to keep the centre of the tree open.

Pruning in the Succeeding Year.—This will consist chiefly in thinning out weak shoots from the body of the trees where they appear to be too thick, and in slightly shortening the longest leading shoots at the end of the main branches. Indeed, this is the principle which should guide the pruner in his work of pruning in future years. Thin out the trees to let in light and air where growth is too thick, selecting the weakest shoots and those, if any, which grow across the body of the trees for cutting out, and slightly shorten back the longest of the leading young shoots as pointed out above. Standard orchard trees should never be overpruned.

Varieties to Plant.—In respect to a strictly utilitarian orchard such as this, it is necessary to be on one's guard to plant only those varieties which are healthy growers and free and consistent bearers. This means that some of our best-flavoured Apples, such as Cox's Orange Pippin and Ribston Pippin, must be left out, or at any rate only a tree or two planted, as they are not robust growers, and, moreover, they are much addicted to canker. Another point we have to consider in the varieties we plant in such an orchard as this is the suitability of the fruit for sale purposes, because no doubt most of it would in due course find its way to market. This has been considered in making up the following list of eighteen dessert varieties and the same number of cooking varieties:

Apples, dessert.—Gladstone, ripe July; Irish Peach, August; Devonshire Quarrenden, August; Worcester Pearmain, September; James Grieve, September and October; Ellison's Orange, October; Cox's Orange Pippin (two trees only), November and December; Allington Pippin, December and January; King of the Pippins, December and January; William Crump (new Apple), December and January; Adam's Pearmain, January; Christmas Pearmain, December and January; Blenheim Orange, December and January; Scarlet Nonpareil, December and January; Barnack Beauty, January and February; May Queen, February and March; Brownlee's Russet, February and March; and Sturmer Pippin, March and April.

Apples, kitchen.—Early Victoria, ripe July and August; Potts' Seedling, August and September; Grenadier, September and October; Gascoyne's Scarlet, October; Royal Jubilee, October and November; Blenheim Orange, December and January; Mère du Ménage, January

to April; Warner's King (on warm soil only), November; Norfolk Beauty, November and December; Tower of Glamis, January and February; Lane's Prince Albert, February and March; Bismarck, Christmas to February; Belle de Boskoop, January to April; Bramley's Seedling, January to April; Newton Wonder (better than Wellington), January to April; Lord Derby, December; Annie Elizabeth, March and April; and Wagener (latest of all), May.

Plums.—A selection of nine varieties of standard Plum trees: The Czar (cooking), ripe early in August; Denniston's Superb Gage (dessert), early in August; Jefferson's Gage (dessert), early in September; Monarch (dessert or cooking), early in October; Oullin's Golden Gage, early in August; Rivers' Early Prolific, early in July; Victoria (plant most of this, dessert or cooking), September; Reine Claude de Bavay (dessert), September; and Coe's Golden Drop, October.

Pears.—These are not so useful in a cottage orchard as are Apples and Plums. At the same time it would be a mistake not to include a few trees, say, a score. These could be planted between the rows of standards as pyramid or bush trees, and I would suggest they be planted at the end next the house, so as to be more under observation when ripening. Of these I give nine suitable varieties: Williams' Bon Chrétien, ripe September; Triomphe de Vienne, September; Conference, October and November; Louise Bonne of Jersey, October and November; Marie Louise, November; Doyenné du Comice, November; Vicar of Winkfield (cooking), December; Blickling, December and January; and Le Lectier.

Following after the Pear trees, between the standard Apple and Plum trees I recommend that Gooseberries, Raspberries, Black, Red and White Currants, also Strawberries, be planted, leaving a large enough space at the bottom end of the orchard furthest from the cottage (among the standard Apple and Plum trees) to grow an ample supply of vegetables. On either side of the centre row spoken of before I would suggest that a row of Loganberry bushes be planted at 9 feet apart and trained over rough timber trellis over the pathway. As well as being useful, this would add a touch of ornament to that part of the orchard. At the end of from seven to ten years the produce of this half-acre orchard, if well looked after, ought to be worth on an average, even at a low estimate, from £25 to £30 a year, or, say, from 10s. to 12s. a week. It is not necessary to point out what a boon and a blessing such an adjunct would prove to a working-man's home.

OWEN THOMAS, V.M.H.

GARDENING ACROSTICS.

DOUBLE ACROSTIC No. 6.

A famous Swiss botanist of the sixteenth century, who, after having collected 1,500 drawings to illustrate a history of plants, died before he could publish the work:

Firsts—His Christian name.

Lasts—His surname.

1. An English name for the Gladiolus.
2. A seed before it is fertilised.
3. A genus of Filices, which takes its name from the kidney-shaped covering of the sori.
4. A Campanula whose roots may be used as a vegetable and its leaves in a salad. Seldom seen now. English name.
5. The fruit of the world.

6. A famous and graceful Himalayan tree introduced to Britain about ninety years ago. Its usual English name.

Solutions of the foregoing must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, January 17. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 4.

HERBAL—SALMON.

- | | | | |
|------|---|---------------------|---|
| * 1. | H | YACINTHUS ORIENTALI | S |
| † 2. | E | VELYN'S SYLV | A |
| ‡ 3. | R | EGE | L |
| § 4. | B | LENHEI | M |
| 5. | A | RBUTUS UNED | O |
| ¶ 6. | L | OUDO | N |

William Salmon, doctor to Queen Anne, published his Herbal in 1710. It is a huge volume, and from his fulsome dedication to the Queen we may safely say he was "in a big way" when he wrote it. It is the last of the great Herbals. * The Dutch were afraid of a Hyacinth mania about 1734, on the lines of the disastrous Tulip mania of a century before, so much so that a book of that period was republished as a warning of what might be expected if prices became unduly inflated. † Evelyn was both a gardener and a statesman. His "Sylva" was published in 1664, partly to encourage the planting of Oak trees for the Navy. ‡ The elder Regel was one of the best-known European botanists of the last century. For a list of his works see Jackson's "Guide to the Literature of Botany." § Lancelot Brown, a landscape gardener of the eighteenth century. He excelled in his management of water. He was nicknamed "Capability" Brown, from his habit of remarking that a place had great "capabilities."—Johnson's "History of English Gardening," page 265. || Arbutus Unedo is popularly called the Strawberry Tree.—Nicholson's Dictionary of Gardening. ¶ J. C. Loudon's "Encyclopædia of Gardening" is a mine of information on everything connected with gardening. It was published in 1829. After Loudon's death new and revised editions continued to be published by his widow. The last we have seen is dated 1860. The early editions are particularly valuable on account of their good bibliography, which is omitted in all later ones. Felton, in his work on the "Portraits of Authors on Gardening," draws much of his information from this source.

RESULT OF ACROSTIC No. 4.

In accordance with our rules, it was possible to secure eight marks, one for each correct "first" and "last," and one for each correct light. The following marks have been awarded:

Seven marks.—L. A. Loudon, "Ping," "Judith" and "White Lady."

Six marks.—"Tempus Fugit," "Hero," R. Chapman, "Jan," "Penwarne," "Nautilus," "Westbank," "Tortoise," "Boarsvale" and "Rusticus."

Five marks.—"Miller," "St. Kevins," Miss G. H. Jeffreys, "Elm" and "M. M."

Four marks.—William Acworth and G. D. King.

Three marks.—A. Henderson, W. Bond and W. Slocombe.

One mark.—W. Garwood and E. Ballard.

As stated in Rule No. 5, published in our issue for November 22, 1913, Acrostic No. 1 completes the first series. In this series it was possible to get a total of 41 marks, and we give

below the names of those who secured 30 marks and over: "White Lady," 38; L. A. Loudon, 38; "Hero," 37; R. Chapman, 37; "Ping," 37; "Nautilus," 36; "Jan," 35; "Rusticus," 35; "Westbank," 35; "Elm," 34; "Boarsvale," 33; "Judith," 33; "Tortoise," 32; "Miller," 31; and "W. R. D.," 30. Under Rule 8, the first prize of two guineas and the second prize of one guinea will be added together and divided between

"WHITE LADY" and L. A. LOUDON.

Under Rule 5, these two competitors will be penalised 12 points in the second series, *i.e.*, Acrostics Nos. 5 to 8 inclusive.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation, he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS (La France).—The weak condition may be the result of overcrowded plants, or this in conjunction with the distance they are from the light. The vinery is not the best place for them, seeing they require the fullest light. Cannot you erect a temporary shelf for a few weeks? If so, and if you could also give the plants a shift into 8-inch pots, an appreciable improvement might ensue. A little bone-meal with the soil might also strengthen the plants. If you have enough rods, train the Rose out fan shape, and in January cut it back to one-half the length of the shoots or to the position of a good plump eye or bud. You do not say if the plant is in a cold or heated greenhouse, and you give no particulars as to the mature condition of the growth or whether early flowers are required or not, all of which would have assisted to a more helpful reply.

PLANTS FOR EDGING A BORDER (X. Y. Z.).—Yellow-flowered subjects suitable for this purpose are decidedly few. While the yellow Alyssum is remarkably showy in spring, it is not seen to advantage during the summer months. Sedum kamtschaticum is a pretty yellow-flowering species that grows about six inches high and blooms for some time in the summer. Iberis correifolia forms a pretty evergreen edging, and so does the small Periwinkle, Vinca minor. An edging that we have had under our notice, and which much impressed us throughout last summer, consisted of a band of Nepeta Mussinii, and we think this would not fail to give you satisfaction. It grows about fifteen inches high, and the masses of soft greyish-toned foliage impart to it a most restful and pleasing character. The spikes of pale lavender blue flowers, so freely borne throughout the summer, form an additional feature of attraction.

CALIFORNIAN POPPIES (H. W.).—There are two Californian Poppies, and you do not say to which one you refer. One is a shrubby, and in some gardens a sub-shrubby plant, with glaucous leaves and large white flowers. This is known as Romneya Coulteri, or Californian Tree Poppy. The other is an annual plant called Eschscholtzia californica. Both belong to the Poppy family, though neither is a true Poppy. If it is the former plant to which you refer, the seeds may be sown on arrival in light, sandy soil in a warm greenhouse. When the seedlings are large enough to handle, prick them off singly in boxes at a distance of 2 inches apart each way. When well established, place them in a cool and airy frame, and plant out in a nursery border in May. They ought to flower when two years old. If the Eschscholtzia is meant, keep the seeds in a cool place until March, then sow them thinly in light soil in a herbaceous border. Allow plenty of room, and eventually thin the plants out so that they stand at a distance of 9 inches or so apart. This is a very easy plant to grow, and often reproduces itself year after year from seeds left in the ground. The fine flowered named kinds are apt to deteriorate, however, if allowed to do this.

BROMPTON STOCKS GONE WRONG (I. W. F.).—We have carefully examined the leaves of the Brompton Stocks and have failed to find any trace of fungus in them. Their appearance suggests that there may be wireworm or something of that kind at their roots.

VIOLETS AND RED SPIDER (Blacklock).—The Violets are very badly attacked by red spider. The plants have probably been kept too dry, and almost certainly too warm and close. Syringe them with a solution of potassium sulphide, made at the rate of 1oz. of the sulphide to three gallons of water.

CARPET PLANTS FOR STANDARD FUCHSIAS (E. B.).—Some of the bedding Violas form a good groundwork for standard Fuchsias; indeed, we do not think you will improve upon them for the purpose. For Fuchsia Mrs. Marshall, the soft mauve variety Maggie Mott, one of the very best of bedders, would form a pleasing combination; but if you prefer a Viola of a darker tone, then we can recommend J. B. Riding, a rich, rosy claret-coloured flower. Dwarf plants of a good Heliotrope, such as Lord Roberts, would also be well suited for the purpose.

PLANTS FOR SHADED ROCKERY (Zameibe).—You ask for the names of some "common rock plants for a tree-shaded rockery." Any of those named below should succeed, though the measure of success would be in proportion to the degree of shade, not many plants thriving in dense shade. Arabis albidia, A. a. flore pleno, Alyssum saxatile, Aubrietias in shades of blue, lilac, violet, pink and purple, Iberis sempervirens, Coronilla varia, C. iberica, Campanula muralis, C. pusilla, C. p. alba, Polygonum affine, Mossy Saxifrage in variety, Acantholimon glumaceum, Megasea cordifolia, M. c. purpurea, Orobanchaceae, O. vernus, Saponaria ocyroides, Veronica prostrata, Crucianella stylosa coccinea, Achillea tomentosa, Acaena microphylla, Helianthemum in variety, Sedum spurium coccineum, S. kamtschaticum, S. pulchellum, S. middendorffiana, Hepaticas and Omphalodes verna. Interspersed among these might appear Snowdrops, Chionodoxas, Scillas, Leucojum vernum, autumn and winter flowering Crocuses, Anemone apennina, the Winter Aconite, and other bulbous or tuberous rooted plants.

VARIOUS QUESTIONS (Daisy).—The flowering-time of the Verbascum would be influenced by the locality, and as you appear to live in a cold district, the plants may not flower before August. Both kinds are perennial, but for decorative effect are best regarded as biennials, whose good flowering would depend upon the leaf development in the first year. Mid-April we should consider too late a date for sowing, if the idea is to get good specimens. Sutton's Pink Antirrhinum would be best for the border; the Swan River Daisy would be much too dwarf behind the Nepeta, and even the intermediate Antirrhinum would not be any too tall. You may, however, get the shade of colour in the tall Antirrhinum if you wish. A useful annual for carpeting the Azalea bed would be Alyssum maritimum compactum; it is white flowered, dwarf and free. A much better way of carpeting such a bed would be to plant some of the hardy Heaths, either Erica carnea or a good red form of E. vulgaris, such as Alportii. This would flower in autumn; the first named would flower during the winter months.

BULBOUS FLOWERING PLANTS FOR CHURCH DECORATIONS (B. W. A.).—The most suitable bulbous plants for your purpose would be Daffodils, Tulips and Spanish Irises, and a selection of each of these would provide flowers for cutting in April, May and June. The best Daffodils would be Golden Spur, Emperor, Empress, Barri conspicuus, Sir Watkin, grandis, ornatus, Poeticus, recurvus, Sulphur Phoenix and albicans; of Tulips, Yellow Prince, White Pottebakker, White Swan, Rosa Mundi and Prince of Austria among the early or bedding sorts, with Bouton d'Or, Flame, Golden Spire, Inglescombe Pink, Inglescombe Scarlet and The Fawn among May-flowering and Cottage varieties. To these could be added some late-flowering Darwin sorts, though we consider the above of a more useful character for the object in view. Of the Irises, British Queen (white), Chrysolora (yellow), Bronze King and Excelsior would be good. Paonies, both single and double, would be serviceable, though the former do not last long. Iris Kämpferi we should not consider quite suitable. The best plants for later flowering, also to be planted before the middle of February, would be Liliums longiflorum and speciosum album Krætzerei. The so-called Spiraea japonica would best suit your requirements.

TREES AND SHRUBS.

FLOWERING SHRUBS FOR A SUNNY PLACE (E. C.).—The following eight shrubs may be expected to give satisfactory results if planted under the conditions you describe: Berberis stenophylla, Spiraea arguta, Ribes sanguineum atrosanguineum, Diervilla Abel Carrière, Viburnum tomentosum plicatum, Cistus laurifolius, Philadelphus Lemoinei erecta and Forsythia suspensa. They may be procured from any of the nurserymen who advertise trees and shrubs in THE GARDEN.

SHRUBS FOR FLOWERS (W. G.).—The following should be of service to you in the circumstances: Philadelphus grandiflora, P. Lemoinei erectus, P. Mont Blanc; Lilacs Mme. Abel Chatenay, Marie Legraye, Negro, Mme. Lemoinei; Berberis Darwinii, B. stenophylla, Forsythia suspensa, F. Aitchisonii, Weigela Abel Carrière, W. van Houtte, Buddleia variabilis, B. veitchianus, Daphne Mezereum, and Rosa rugosa. You say nothing of the size and extent of the border, or the soil, but if greater variety should be desired you might, provided the soil is suitable, add hybrid Rhododendrons and the hardy Azaleas, the latter being particularly valuable both at flowering-time and for rich foliage effects in autumn.

SCALE ON MYRTLE (W. G. S.).—The Myrtle is badly attacked by scale insects and will be very difficult to clean. As many as possible of the little blisters should be removed with a blunt stick, assisted by a dip of soft soap (a handful) into which flowers of sulphur have been kneaded, dissolved in one and a-half gallons of soft water. After this has been done, spray the plant well at weekly intervals for three weeks with paraffin emulsion, spraying with clear water between the operations.

INJURY TO RHODODENDRON FOLIAGE (Pink Pearl).—The damage done to the foliage of the Rhododendrons is not the result of the attack of a fungus, though one is present on some of the leaves, but the result of drought in the past summer. When once the soil in which the plant is growing becomes really dry, the fungus, which plays the part of root-hairs in these plants, is likely to be killed, and subsequent watering is of little avail. One sees many Azaleas killed through allowing the soil to become dry, and it is the common cause of the death of Heaths in houses.

PRUNING AVENUE TREES (J. D.).—Your avenue trees will certainly require pruning if you wish them to develop into really fine specimens. In any cases where there are rival leaders, all must be removed save the centre one. Also where the branch system is very dense, a number of branches may be removed with advantage. When branches are developing rapidly in width and the trees are not increasing in height to a corresponding extent, the branches should be shortened. Bottom branches may be removed gradually, but do not take many off at once, or too great an area of bark will be exposed to sun which has previously been shaded. All cuts must be made parallel with and close to the bark of the trunk or main branches, and all wounds must be dressed with coal-tar as soon as made.

DWARF-GROWING SHRUBS (Teragram).—The following dwarf-growing shrubs would be likely to give satisfactory results in the bed you describe: Philadelphus Lemoinei erectus, Genista hispanica, Tamarix pentandra, Prunus japonica flore pleno, Kalmia latifolia and Pieris japonica for the back; and Cydonia Maulei superba, Spiraea japonica Anthony Waterer, Daboecia polifolia, Erica cinerea and varieties, Calluna vulgaris and varieties, Erica carnea, Leioophyllum buxifolium, Hypericum moserianum, Berberis Wilsonae, Genista pilosa, Cytisus Beanii, C. kewensis and Kalmia angustifolia varieties for other places. The Ericas, Callunas, Leioophyllum and Hypericum should be planted in small groups. The Eleagnus and Pittosporum you mention are likely to grow at least 12 feet high, and are not suitable to place among small-growing plants.

INJURY TO PRIVET (W. B. S.).—The Privet branch sent for inspection bore the fructification stage of the coral spot fungus (Nectria cinnabarina). This fungus often appears on dead wood, and may usually be found on old Pea sticks, but it is also found on living branches. The spores probably find an entrance through wounds, and the mycelium is present in branches for a considerable time before the visible or fruiting stage appears. By that time the injury is complete and there is no chance of saving an infested branch. It, however, is more often found on branches of trees or shrubs, and may take one branch of a tree and cause no further harm to that particular specimen. On the other hand, it may spread from branch to branch of a shrub and eventually destroy the whole plant. The only way to cope with the disease is to cut away and burn any branch which bears the small red fungus growths, and also all dead wood. As your Privets are old plants, it would, perhaps, be advisable to dig them up and burn them, and begin again with young plants. Vigorous young plants 2 feet to 3 feet high can be procured very cheaply, and they transplant without the slightest fear of them not re-establishing themselves. No real good can be done by using a fungicide for this disease.

THE GREENHOUSE.

INJURY TO SCHIZANTHUSES (Mrs. C.).—The Schizanthus plants are attacked at the root by a fungus, a species of Fusarium, which is killing the lower part of the stem and causing the withering of the upper part. This disease is very similar to, and perhaps identical with, the sleepy disease of Tomatoes. Cure is impossible, and prevention consists in sterilising the soil by steaming it before planting.

PLANTS FOR WINDOW (Mrs. L. W.).—(1) The success attending the cultivation of different plants in the window of your drawing-room speaks highly for the care and attention that you bestow upon them. We have little doubt that a Camellia would succeed under these conditions, but we do not feel so sure of a Cape Heath. Two of the most likely to thrive with this treatment are Erica gracilis, whose myriads of tiny rose purple blossoms are borne in autumn and winter, and Erica melanthra, a winter flowerer with small mauve-coloured blossoms and dark-tinted anthers. These may during the summer be stood out of doors, provided they are well supplied with water. (2) Weak soot-water is a good stimulant for Ferns, but it would be better still to alternate it with a little Clay's Fertilizer, which can be safely applied to Ferns. Of course, you will take care that only a very moderate dose is given. (3) As your Jessamine grows so strongly and yet flowers in a perfectly satisfactory manner, we do not think you can improve upon the practice which has proved to be so successful. It certainly seems a pity to cut away so much wood, but as this is necessary to keep it within bounds, we do not see how it can in any way be avoided. When cutting it back to the necessary extent, any old and exhausted wood should be removed entirely.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Plants Protected from Frost.—Plants that are protected from frost should, during a spell of mild weather, have their covering removed during the day where it is possible, as it helps to retard the plants, which would otherwise become active under the influence of protection. Discretion should be used, for plants that are frozen ought not to be uncovered, but left until the frost has gone. This also applies to plants in frames.

Shortage of Cut Flowers.—During the last ten days cut flowers have been exceedingly scarce, and in Covent Garden Market prices have been higher than for many years past. In the provinces some of the smaller florists' shops have had to resort to artificial flowers to meet the deficiency. The mild weather experienced until Christmas brought many flowers along too rapidly, and those that would under ordinary circumstances have been available now were sold three weeks ago. Since then cold weather has been experienced in France and this country, and has retarded the later crops. The shortage is expected to last for at least another week.

Pruning Winter Jasmine.—This beautiful hardy shrub has flowered earlier than usual in most districts this winter, and now most of the blossoms have departed. Although much pruning is not needed, that which is required should be done during the next few weeks. Unless a bush is overcrowded, or encroaching on space required for other plants, it may be left alone. Where, however, growth is too dense, the oldest shoots ought to be removed. This will encourage the formation of stout growths that will flower freely next winter. If the shrub appears to be starved, a top-dressing, 2 inches thick, of well-decayed manure applied now will work wonders during the growing season.

Davidia involucrata.—There is an interesting reference to this tree in Mr. E. H. Wilson's new book, "A Naturalist in Western China." It appears in the fascinating chapter entitled "In Quest of Flowers": "Ascending a precipice with difficulty we soon reach the Davidia trees. There are over a score of them growing on a steep rocky declivity; they vary from 35 feet to 60 feet in height, and the largest is 6 feet in girth. . . . The distinctive beauty of Davidia is in the two snow white connate bracts which subtend the flower proper. These are always unequal in size, the larger usually 6 inches long by 3 inches broad, and the smaller 3½ inches by 2½ inches. At first greenish, they become pure white as the flowers mature, and change to brown with age. The flowers and their attendant bracts are pendulous on fairly long stalks, and when stirred by the slightest breeze they resemble huge butterflies hovering among the trees. . . . To my mind Davidia involucrata is at once the most

interesting and beautiful of all trees of the north-temperate flora."

To Make Stonework Look Green and Old.—We are occasionally asked if there is any chemical that will make stone steps or pedestals look old permanently. So far as we know there is not, but the following treatment will, in the course of a few weeks or months, give the stone a genuine mossy appearance. Wash down the bark of one or more large trees, and add to the greenish water thus obtained a little cow-manure and very little soot. Paint or sprinkle the stone two or three times with the liquid. If this is done at once, the stone will have taken quite a green, mossy tint by the spring, which will increase as time goes on. Flakes of moss obtained from old walls can frequently be encouraged to establish themselves on the stone, and even if the moss itself dies, the spores almost invariably germinate.

Climbers for Rambling Over Large Trees.—There are many climbing plants that look very effective when rambling over large trees. The common Virginian Creeper, as well as several other forms of Ampelopsis (which, correctly speaking, are Vitis) look very charming during the autumn hanging against the dark foliage of a Pine tree. The same may be said of Polygonum baldschuanicum, with its pink and white trusses of flowers, or P. multiflorum, which is a more vigorous and faster grower. Clematis montana and C. Flammula are excellent for such a purpose, and even the common Traveller's Joy (C. Vitalba) may be used for the wilder parts of the garden, as it is ornamental both in flower and fruit. Rosa moschata will often ramble over the top of a Pine tree 130 feet high, and look quite a picture in summer with its many white flowers. All of them may be planted now, and only require a little attention till they have become established.

Pruning Outdoor Vines.—Grape Vines growing outdoors, either against a wall or poles, should be pruned without delay. If grown upon the spur system, the lateral shoots should be cut back to about two buds from the base; but if on the extension system, the wood growths laid in during the summer to take the place of those that bore fruit during the past year must be cut back to a plump bud, leaving about four feet of the shoots. The last-named system is preferable for Grapes growing out of doors, as the shoots grow away more freely than those on the spur system. Should the Vine be infested with red spider, give the wood a dressing with a mixture of water, soft soap and flowers of sulphur, with quicklime. The mixture is made by boiling 1lb. of sulphur with 2lb. of quicklime in 4 gallons of water; then to every 4oz. of this add 2oz. of soft soap and 1 gallon of boiling water, thoroughly mixing them and keeping the whole stirred when in use. When ready, it may be applied to the bark with a stiff brush and well worked in. This will be found a cheap and effective preparation.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Herb Garden.—Seeing in your issue of THE GARDEN for January 10 a request by one of your correspondents, "Herbs," for advice upon making a herb garden, and being myself interested in making such a garden, I feel I must let him know of an excellent and most charming book entitled "The Herb Garden," written by Mrs. Bardswell and published at 7s. 6d. by Messrs. Black and Son, which has been of the greatest service to me. The book is illustrated in colour, and is full of useful and instructive information, giving lists of many herbs, &c., which the average person would know nothing about, and also the uses to which these can be put. There is so great a charm about the very words "herb garden" that it is most pleasant to find the old love of this phase of gardening reviving. Your correspondent is indeed fortunate to have his herb garden given to him. —GARDEN LOVER.

The Bird of Paradise Flower.—This is the popular and appropriate name given to the South African genus *Strelitzia*. The most magnificent species is *S. Regina*, with large orange and purple flowers of gorgeous colouring. This species and its beautiful variety *citrina* are now to be seen flowering in the Mexican House at Kew, where their striking appearance never fails to arouse the interest of admiring visitors. *S. Regina* was grown at Kew as far back as 1773, but at that time it was not a success, owing, no doubt, to the fact that the roots were confined in flower-pots or tubs. In 1795 a plant flowered for the first time in the Apothecaries' Garden at Chelsea. Here the plant seems to have fared better, owing to its roots having extended by accident into a bed of rotten tan. When planted out in the beds of a warm house or stove, *Strelitzias* grow and flower freely, providing they receive a fair amount of sunshine. The genus is related to *Musa*, and it is interesting to note that in South Africa the seeds of *S. Regina* are eaten by Kaffirs.—C. Q.

Perpetual-Flowering Carnations.—

I was attracted by the note on Carnations, page 24, issue January 10, by Mr. R. P. Brotherston, and particularly by the paragraph wherein he states that propagation begins early in October. While this may answer in Scotland, I venture to state that all the most famous commercial growers will admit that October and November struck cuttings do not make such profitable plants as those struck in December, January or February. At the last conference of the Perpetual Flowering Carnation Society, and also at the one in December, 1912, Mr. C. Engelmann and others stated that they were convinced that the later-struck cuttings were the best from all points of view. Mr. C. Allwood, easily one of the most expert writers on Carnations, explains the why and wherefore, and it is simply this: October cuttings have two dull declining months ahead of them, and during this period they are weakening, not gaining strength. Late December and later cuttings

have brighter days before them. They go ahead and gain strength with the lengthening days, and never look back. Mr. Engelmann publicly stated that his tests over two years proved that January-struck cuttings will give a far larger crop than October or November struck plants.—T. W.

Colour Effects with Annual Flowers.—The coloured illustration of annuals given with January 3 issue presents some problems worth consideration. The pink and rosy carmine on the right are charming, but rendered as a whole less effective by the intrusion of the white *Godetia*. The most faulty part of the composition, however, is the deep blue at the edge. Had cream been used instead, the whole would have been sweetened. Blue, to have been effective with the other colours, should have been very light, or, best of all, mauve, and preferably introduced near the back. The grass verge is too narrow, and at the very least

little more striking, and was as follows: A number of the largest available tubers were selected from some maincrop Potatoes in spring. These were spread out on trays, and the young growths picked off every fortnight till the first week in August. At this date some old potting soil, moderately damp, was got ready, also a good-sized packing-case. A layer of soil 2 inches deep was placed in the bottom of the box, and on it tubers were laid 2 inches apart from surface to surface, and this was repeated till the case was filled, finishing off with the usual layer of soil. The case was then placed in an outhouse and allowed to remain there till the Potatoes were wanted at Christmas-time. The case was then emptied of its contents by being turned upside down, when it was found that the old tubers (now shrivelled up) had, without the aid of leaf, stem or light, produced a fair crop of nice young

tubers, dry and mealy. I may say that in both cases the tubers had the flavour characteristic of young Potatoes grown under normal conditions. I am aware that these methods are not new, but they do not appear to be generally known.—CHARLES COMFORT, *Midlothian*.

Two Excellent Kales.—There are two varieties of Kale that do not seem to be generally known, but that are both of such high merit that they should be in every garden where the best vegetables are appreciated. The Marrow Kale is for summer and autumn and until frost comes, for it is not very hardy. The stem is the part eaten. The leaves of a coarse kind have long been used as cattle food, especially on the Continent; but the garden kind, cut before the stem has become hard and fibrous, is a truly delicious vegetable. In taste it is much like Kohl Rabi, but is more tender in consistency and more delicate in flavour. The stem is nearly two feet long, a little swollen in the middle of the length. To prepare it for table the outer skin is cut off, and the stem, which will now be about an inch in diameter, is cut across in sections rather less than a quarter of an inch thick, boiled in salted water and served with a thin white sauce. The other kind is the Russian Kale. What is now offered must be a recently much-improved kind, for in that admirable book, "The Vegetable Garden," by Messrs. Vilmorin, it is described as worthless. Certainly the vegetable I am now

enjoying, and which I grew, together with the Marrow Kale, by the advice of a representative of Messrs. James Carter and Co., who sent me the seed, is quite the best of the several kinds of Cabbage I have now in the garden. It has a tender texture and an excellent flavour, with that pleasant sweetness that the hardy Cabbages seem only to acquire when they have felt the frost. When half grown the Russian Kale has a curious appearance. The earlier leaves have hardly any blade, and the whitish ribs and nerves stand out like the branches of stags' horns. Now it has the central rosette of more normal Cabbage form, which is the edible part. This and the succeeding sprouts will be of great value through the winter, for it is extremely hardy. During the recent trials at Wisley the Russian Kale received high honours.—G. JEKYLL.

A BIRD OF PARADISE FLOWER (*STRELITZIA REGINÆ CITRINA*) NOW FLOWERING IN THE MEXICAN HOUSE AT KEW.

should be twice the width. A deep blue might have been used on the left border, but there also well to the back. On the whole I would incline to banish blue from both borders. I wonder how the compositions strike others who have given colours some attention.—R. P. BROTHERSTON, *Prestonkirk, N.B.*

New Potatoes in Midwinter.—We have had a considerable supply of new (or young) Potatoes during the recent Christmas season, the supply being produced by two distinct and simple methods. The first was by filling biscuit tins with young Potatoes in July. After putting on the close-fitting lids, these were secured in position by means of a piece of lacing wire. The tins were then buried 2 feet deep in the ground, where they were allowed to remain till the Potatoes were wanted. The second method employed was a

The Gold Mohur Tree.—In your issue of the 3rd inst. I find that "G. D." has enquired about the Gold Mohur tree. I know it by appearance very well; it is one of the sights of the Shiny East. I am nearly certain that it is a variety of Poinciana, but I have no books on Eastern botanical subjects, so am unable to verify my assertion. I am inclined to believe that it originally came from the West Indies, but it is found in the cities of India and Ceylon.—P. TILLARD.

Protecting Alpines in Winter.—The rockery as a feature of artistic gardening has come to stay, but the satisfaction of picturesqueness is often nullified by the high mortality among choice plants during the ever-changing climatic conditions of our long winters. Frost is not a danger for serious consideration; but rain, stagnant water and a cold, sodden soil spell ruin to many of our finest plants. I have found that an excellent method of keeping down the number of losses is to scatter gravelly matter round those that I prize most. I have even gone the length of wedging small whinstones, such as are used for roads, round the necks of some plants, and I never yet had cause to regret the time taken up in the work. Keep the foliage off the cold soil, which is almost continuously soaked during these months; see that the "neck" of each plant is kept erect, and the result will be most satisfactory. By careful work of this kind I have managed to keep such dainty little subjects as *Saxifraga Griesbachii* and *S. Stribnryi*, as well as many others, while my nearest neighbour finds that he needs to get a new stock every spring.—CRAIGIELEA, *Glasgow*.

Thatched Cottages.—In reference to the paragraph on page 1 of January 3 issue, while I yield to no one in appreciation of the æsthetic virtues of thatch and detestation of the many ugly modern buildings of all sizes, I think it should not be overlooked that there are some thatched buildings too intimate knowledge of which would certainly entail disenchantment. Thus, I remember a very agreeable railway journey in company with a large family of countryfolk, during which a chance remark in praise of thatch elicited the information that they had suffered greatly from the combination of a sieve-like thatched roof and a miserly landlord. Also I have heard quite alarming stories bearing upon thatch as a harbourage for fleas, and from time to time one reads most harrowing accounts of how quickly fire spreads in a village of thatched roofs. Certainly the question of roofing material seems to me pre-eminently a matter for cottagers to decide for themselves, though there can hardly be a doubt that such people as touring motorists (who are responsible for such serious new discomforts to villagers) would be one and all enthusiastic "thatchites." I really must venture to dissent from the description of the fine large house illustrated on page 9 of your issue of January 3 as a "cottage" (unless, indeed, it refers to the wholly dwarfed edifice faintly discernible in the background). I am, of course, well aware that established usage can be pleaded for calling houses "cottages," which, to my idea, bear about as much resemblance to the genuine article as a pigsty does to a palace; but is it not a most foolish affectation?—ARTHUR GARNETT, *Kew*.

FORTHCOMING EVENT.

January 27.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE value of Chrysanthemum blooms in December and at Christmas-time is very great. In some seasons they are of more value than in others. Notwithstanding the fact that the past month has been a favourable one for flowers of various kinds, those of the Autumn Queen have been more appreciated than ever, and the quality of the blooms has been higher, too. I think the principal reason for the high quality and general good appearance of the flowers is the fact that more cultivators have restricted the number of varieties grown and had more plants of each.

Scarcity of Cuttings.—There was a general scarcity of cuttings on the old roots of many varieties last year, notably on those grown for late blooming. The old stools must be carefully preserved on high shelves in greenhouses or in cold frames. If space cannot be spared for the old plants in their large pots, carefully turn out the balls of soil, remove the drainage and reduce the balls quite two-thirds. Then pack them close together in boxes about six inches deep, filling up all spaces with a compost of sand, sifted loam and leaf-soil. Make it moderately firm, water through a fine-rosed watering-can, and place the boxes in a warm position in a greenhouse. I have often secured a nice lot of sucker cuttings in the way described from old plants that seemed to be quite hopeless. Amateur cultivators who like to grow a good batch of plants for the supply of cut flowers at Christmas-time should now duly note how the varieties they have grown this season have succeeded. Then any failures experienced can be avoided another year. The following are

Splendid Varieties for the production of blooms late in December, at Christmas and during the first half of January: Mme. Oberthur, white; Helena Williams, a pale yellow sport from the latter; Mrs. David Syme, pure white, greenish centre; A. J. Balfour, a lovely pink, compact blooms; December Gold, mid-December; Mrs. H. Turner, velvety crimson (when the plants are pinched they branch freely); Mary Thorpe, soft pink, easy to grow as a bush, on which two dozen blooms may be grown; Niveus, a good white; Queen of the Exe, pale blush, the plant lifts well; Thorpe's Apricot, a lovely flower for table decoration; and Souvenir de Scalarandis, deep bronze, one of the best for planting out and lifting. A good companion to the variety A. J. Balfour is Thorpe's Christmas Rose, which is a deep rose pink in colour. William Turner, if grown as a bush, would come in early in December. For Christmas-time and a week or two later Western King, pure white; Nagoya, a deep golden yellow that keeps well; Baldock's Crimson; Mrs. Greenfield, golden yellow, reflexed blooms; Mrs. J. Thompson, pure white; and Embleme Poitevine, an incurved, pure yellow, should be grown. If two yellows and two whites only are required, then select Embleme Poitevine, Nagoya, Mrs. J. Thompson and Western King. It is important to commence with good sturdy cuttings that are produced from the base of the old plants, and to avoid stem cuttings.

AVON

THE WINTER SPRAYING OF FRUIT TREES.

THE practice of spraying is becoming much more common than formerly. Fruit-growers are realising the importance of the work when carried out properly. They find, when spraying is done systematically during the winter, spring and summer, that the trees give much better results. There is no doubt that if spraying and other preventive measures to check the spread of various insect pests and fungoid diseases were made compulsory by Government, all fruit-growers would benefit to a considerable extent.

Spraying while the trees are dormant is an excellent time for the inexperienced to make a start, as there is not the same risk as when the trees have made leaves, although there is not the slightest reason why an injury should be done to the most delicate tree if the instructions given are carefully carried out.

Several home-made sprays can be employed at this season with advantage, and as some prefer to prepare their own washes, I will give a few simple recipes for the removal of moss and lichen from the trees, also of such pests as eggs of the winter moth, woolly aphis, mussel scale, ova, Apple blossom weevil, oyster-shell bark lice, earwigs and the caterpillar of the Codlin moth in its cocoon.

Lime-Wash.—One of the most safe, efficacious and easily applied is quicklime. Not only does lime cleanse the trees of moss and other extraneous growth, but it is valuable as a stimulant to crops growing underneath the trees, as well as being beneficial to the trees themselves, especially where lime is deficient in the soil. In sandy soil, or in that with a gravel or clay subsoil, lime is largely employed by fruit-growers for the double purpose. The best hard-stone lime is necessary, as obtained from Buxton; not that which is soft, as is sometimes the case when made from some kinds of chalk. Eighty-six pounds of lime are sufficient for fifty gallons of water. This amount of lime should be put into a galvanised vessel, adding a small quantity of water to start the lime dissolving. As this proceeds add more water, constantly stirring the whole with a shovel, never allowing it to become quite dry nor making it too wet. Just keep it sufficiently thin to stir and become regularly dissolved. When this has taken place, strain the whole through a fine sieve into another vessel to remove any small portions that may tend to choke the pumps or spray nozzles. Add water sufficient for the quantity noted. There are various times when lime spraying can be done. Some begin in November and December, others not until the buds are bursting in spring. In my case I usually begin the second week in April. A large grower of Plums near here does not spray the trees until the blooms are fully developed, and although many persons would be afraid to do this so late, I can assure readers there is no danger in so doing. The kind of sprayer to use is purely a matter of choice. I prefer one with a pneumatic action, which leaves both hands at liberty to work the sprays. Various lengths of hose and lances are required, according to the height of the trees to be sprayed. Practice will soon teach a person how much liquid to use in coating the trees. It is surprising what a small quantity is required to cover a branch. The clusters of spurs and cankered portions—if any

should be carefully covered, as it is in such hiding-places that the insects lurk. A spraying syringe answers well where only a few trees have to be done.

Copper Sulphate makes a capital winter wash for Apple scab, which is one of the worst enemies the Apple-grower has to contend with. Dissolve 2lb. of copper sulphate in 50 gallons of soft water. This is a cheap wash, and will kill all fungus with which it comes in contact. In applying this wash, use a fine nozzle, making a thin spray and thoroughly forcing the liquid into any cankered parts.

Lime Soda and Salt Wash is easily made and applied, and prevents the hatching of the eggs of Apple sucker and Plum aphid, and also cleanses the trees of moss and lichen. The quantities are 1½cwt. of good hardstone lime, 35lb. of agricultural salt and 3lb. of common washing soda to 100 gallons of water. Slake and strain the lime through a fine sieve, dissolve the soda in hot and the salt in cold water, adding both to the strained lime. February is early enough to commence this spraying, continuing until the buds are ready to burst; then cease.

Woburn Wash.—What is known as the Woburn wash, and an effective one, is applied from November until the end of February. It is made as follows: Caustic soda, 1½lb.; copper sulphate, 1½lb.; lime, ½lb.; paraffin emulsion, 5 pints; water, 10 gallons. Dissolve the copper sulphate in 6 gallons of water and slake the lime in 3 gallons of water. The dissolved copper sulphate should be run through a fine sieve to remove any portions of a gritty character. Then add the paraffin emulsion and stir them together, adding the caustic soda previously dissolved and sufficient water to make 10 gallons. The paraffin emulsion requires careful preparation. Boil a gallon of skim milk gently, adding 2 gallons of paraffin by pouring it gently into the middle of the milk, but not in sufficient quantity to take the milk off the boil. Add 1½lb. of soft soap, gently whipping it up in the middle of the vessel. Keep it away from the side of the vessel, as it is so liable to burn.

Of prepared washes which I know to be effective and which are no trouble to prepare, Bentley's Concentrated Alkali Wash is most efficacious in cleansing the trees from moss and lichen, rendering the bark quite bright and imparting a dark colour to it. In using this mixture I would caution users not to drench the trees unnecessarily with it, especially standards, because the stems become too saturated with the wash running down, collecting as it does from the branches to the stem, and, of course, the older the tree the more numerous are the lodgments in the stem for the wash to collect. Simply moisten the whole of the branches with a fine spray that is sufficient for the purpose. Dissolve the contents of one tin in 15 gallons of slightly warm, soft water.

Bishop's Waltham, Hants. E. MOLYNEUX.

A BEAUTIFUL BARBERRY.

BERBERIS POLYANTHA.

THIS ornamental Barberry was introduced a few years ago from China by Mr. E. H. Wilson, who describes it as one of the best flowering shrubs in the whole of the Berberis family native of China. A deciduous species, *B. polyantha* grows 5 feet to 10 feet in height, forming a large, much-branched bush. The leaves grow in clusters, pleasing light green in colour, obovate, and about an inch long. The attractive golden yellow flowers are borne in fairly large panicles, which are 6 inches or more in length. These are followed by numerous

FRUITING SPRAYS OF THE NEW BERBERIS POLYANTHA. THIS IS ONE OF THE MOST BEAUTIFUL SPECIES OF ITS FAMILY.

rather small coral red fruits, which hang on the bushes into the New Year, long after the foliage has fallen. It thrives under similar conditions to other members of the family, and is readily raised from seeds. Mr. A. E. Pratt, who collected herbarium specimens in Western China during 1889 and 1890, appears to have been the first to discover the plant, though it was apparently left to Mr. E. H. Wilson to introduce the first plants to our gardens. He collected seeds at an altitude of 6,000 feet to 10,000 feet on the uplands of the Chino-Tibetan borderland.

COLOURED PLATE.

PLATE 1485.

RAISING TUBEROUS BEGONIAS FROM SEED.

TIME was when tuberous Begonias were largely increased by means of cuttings, but now the art of seed-saving has become such an exact science that the single varieties can be practically obtained true from seed. For the choicer double forms propagation by cuttings is still followed, but seed saved from a good collection will yield a large percentage of fine double flowers such as are invaluable for purposes of decoration, either indoors or out. Begonia seed may be sown any time during the first three or four months of the year; but where the plants are required to yield a good return of blossoms during the summer of the year in which they are sown, this operation must be carried out in January or February. The pots or pans must be perfectly clean and effectually drained to within 2 inches or 3 inches of the surface.

The Best Soil for Seed-Sowing.

—A suitable compost for the reception of the seeds may be formed of two parts of good friable loam to three parts of leaf-mould, with a liberal sprinkling of sand or equal parts of leaf-mould and loam and sand combined. This material must then be thoroughly rubbed through a sieve with a quarter of an inch mesh, the rougher portions being put on one side in order to place them immediately over the drainage material. The leaf-mould used must be of good quality, and, if possible, from such trees as Oak and Beech. It will be a very great advantage to thoroughly sterilise the soil before using. The prepared compost which has passed through the quarter of an inch mesh may then be put in its place to within half an inch of the rim of the pot. It must be pressed down moderately firm and made level, but not patted hard on the top, as is so often done. Next pass a little of the prepared soil through a sieve with an eighth of an inch mesh, and finish off the pots or pans with a layer of this finer material. The soil must then be thoroughly watered, which may be done by means of a very fine rose; but a better plan is to stand the

pots or pans in a vessel of water, which must be below the rims of the receptacles. In this way the water will slowly enter by the hole in the bottom and gradually soak through the whole of the soil. After the seed is sown, watering must be done in the same way, as by this means the minute seeds are not disturbed in the least.

Sowing the Seed.—The pots having been prepared and watered, the seed should be sown while the surface is still wet, and on this the tiny seeds will at once adhere. Great care must be

taken not to sow too thickly, to obviate which some cultivators mix a little very dry and fine silver sand with it, while others prefer to sow direct without this mixture. From its minute character the seed will not need covering, but a sheet of glass may be laid over the pot till germination takes place.

After-Treatment.—The pots must then be placed in a structure with a minimum night temperature of 65°, rising, of course, during the day. If the weather is genial, the soil may require no more watering till the young plants appear; but in any case, if watering is needed, it should be done as before directed.

The Seedlings.—As soon as the tiny plants are large enough to handle, they must be pricked off into other pots, pans or boxes. These should be prepared in much the same way as for the sowing of the seed. The operation of pricking off is an exceedingly delicate one, and is best accomplished by using two pointed sticks about the size of a pencil. In one a notch should be cut in the shape of a narrow V. This must be manipulated by the left hand, its use being to lift up the tiny plant and place it in a hole previously prepared by the pointed stick held in the right hand. This must also be used to press the soil around the roots. When a pot is finished, it must be watered as before and returned to the warm structure whence it has come. Shading from bright sunshine will, of course, be necessary, but particularly so till the roots take possession of the new soil.

The Young Plants.—As the young plants develop they must, when sufficiently advanced, be potted singly into 2½-inch or 3-inch pots, using much the same compost as before, but it need not be sifted so finely. They must not be allowed to get pot-bound, and for their next shift a larger proportion of loam may be added to the compost. Before bedding-out-time the plants should be gradually hardened off, at which period they will, if they have done well, be good, sturdy examples in 4-inch pots. From these pots those intended for bedding may be planted out; but where required for greenhouse decoration, they must be shifted into larger pots. If carefully attended to, they will flower throughout the summer and well on into the autumn. The principal pests that attack tuberous Begonias are aphides, the Begonia mite and eelworm. Aphides can be readily destroyed by fumigation or vaporising, while this latter, if persisted in, will keep the mite in check. This mite is a most insidious foe, as it often does irreparable damage before its presence is suspected. Badly affected plants should be dipped in some insecticide into whose composition nicotine enters largely. Eelworm, which has been a good deal in evidence within the last few years, is present in the soil and makes its way into the tissues of the plant. The potting soil should be sterilised in some way or other. A very simple method was given by Mr. C. F. Langdon of Bath in his paper read at a meeting of the Royal Horticultural Society last August, namely, to mix a 4-inch potful of newly slaked lime with every eight bushels

of soil, well mixing it a few days before using. He advised the use of a little more lime on suspected soils.

H. P.

[The plant from which our coloured plate was prepared was kindly furnished by Messrs. T. S. Ware, Limited, of Feltham.—ED.]

A LITTLE-KNOWN ORCHID.

PAPHINIA CRISTATA.

THE Orchid family contains many remarkable species and varieties. Many of them are of a very complex structure, and some are of surpassing beauty. The singular-looking species illustrated on this page may perhaps be considered more curious than beautiful. It is, however, of very striking appearance. The flowers on the outside are more or less white, but within they

SOME USEFUL PLANTS FOR THE ROCK GARDEN.

ERODIUMS OR HERON'S BILLS.

THE genus *Erodium* does not seem to be cultivated in the alpine garden so much as its beauty and decorative value justifies. While some species are inclined to be tender—or at least liable to vanish during our miserable winters—very many of them are by no means difficult to cultivate, provided we give them very gritty soil from which all surplus moisture readily drains away, and a position open to the sun all day. When visiting Geneva last summer I was much struck by the varied species of *Erodium* grown by M. Dallinges at

A RARE ORCHID (PAPHINIA CRISTATA). THE FLOWERS ARE BANDED AND STRIPED IN DEEP, CHOCOLATE PURPLE.

are interruptedly banded and striped with deep purple or chocolate maroon.

Moreover, the flowers are crested—hence the specific name *cristata*—and the heavily lined sepals and petals are from 3 inches to 4 inches long.

This plant has in recent times created a good deal of interest among lovers of rare Orchids, and last July it was granted an award of merit from the Royal Horticultural Society when shown by Messrs. Charlesworth and Co., Hayward's Heath. It is not, however, a new species, for it was introduced from Trinidad as long ago as 1834.

In common with many other orchidaceous plants, *Paphinia cristata* has the misfortune to possess many synonyms. In addition to its present name it has been placed under the genera *Maxillaria* and *Lycaste*, although the specific name *cristata* has been applied in all instances

Chêne-Bourg, a suburb of that beautiful city, and later I obtained a collection from him. For their reception I rebuilt a portion of my tiny garden, putting in, at a depth of 2 feet, a layer 6 inches thick of burnt ballast the size of chickens' eggs, and above this a compost of loam, sand, burnt ballast grit, and old mortar, in about equal proportions, in addition to a small quantity of leaf-mould.

Among the species which are thriving apace under these conditions are *Erodium chrysanthum*, *E. Guiccardi*, *E. daucoides* (the Carrot-leaved *Erodium*), *E. macradenum*, *E. sibthorpiatum*, *E. corsicum*, *E. supracanum*, together with its beautiful white form, and *E. trichomanetolium*. As will be seen from the illustration on page 34, the foliage of the last-named plant is very dwarf, compact, and somewhat glaucous; indeed, under certain conditions of lighting it is quite silvery. The

flowers are white, with five rosy purple veins on each of the five petals. The two upper petals display a silvery black blotch at their base, and upon these the veins are very pronounced. During the end of May, through June and July until August, the flowers were produced in quantities, while seed was formed from every blossom.

One very interesting feature in connection with many of the *Erodiums* is the way in which the angle of the flower-stalks varies after the embryo fruit is pollinated. As a rule, the flowers are produced in clusters of five upon short stalks, rising from the upper part of a rigid main stalk some 5 inches or 9 inches long; and when they open they are in the same plane as this main stalk, viz., pointing upwards. After the fruit is fertilised, the short footstalk bends from the point of juncture at a right angle (sometimes even more than 150°), while the fruit itself also alters its angle upon the

ROSE-GROWING IN TOWN GARDENS.

GOOD red Roses are still scarce in the Hybrid Tea section, despite the efforts of the principal raisers to fulfil our requirements. It would seem now, however, that we are within measurable distance of having our desires gratified in this respect. Readers of Mr. Molyneux's interesting "Notes on the Newer Roses" will have observed his unstinted praise of George Dickson. Everything seems to point to this variety becoming the most popular red for town as well as country, and I have heard nothing but praise of it yet. Of Edward Mawley great things were expected, but it has proved disappointing.

flowering. G. C. Waud, Leslie Holland and Château de Clos Vougeot are all beautiful Roses but cannot be recommended for towns. Grusen Teplitz should be grown as a free bush and left practically unpruned. Under favourable conditions it is then good, both early and late. Only those with ample space should plant it.

The Lyon Rose is one few gardeners would care to be without. It may not be all that a town Rose should be, but one can forgive its few faults for its numerous virtues. Betty is quite a good Rose to grow, as is also Earl of Warwick, which is especially good in autumn. These Roses of combined yellow and pink shades always commend themselves, particularly to ladies. Usually they are rather variable in colour, hot weather fading the yellow in them until it is hardly perceptible. Betty has few and long petals, while Earl of Warwick is full. Both can be exhibited. Pharis-

säer and Mme. Leon Pain are also rather alike in colour of the Chatenay type. Both are excellent town Roses, the last named being the better for the garden, of deeper colouring and more profuse in flowering, though Pharisäer produces rather larger blooms. Lady Ash-town, in many other respects ideal, is badly subject to mildew, but those who can cope with this should always grow it. Colour and shape are both exquisite.

Princess Marie Mertchersky is a satisfactory Rose that always seems to come well, and Mrs. Theodore Roosevelt is also of perfect shape. Both are good, but not comparable with Mme. Leon Pain, for instance, in point of freedom of flowering. Of light pinks, Augustine Guinoisseau is most satisfactory for bedding. Lady Ursula would be far more useful if it were not so reluctant to open its flowers, those on the smaller shoots being practically useless.

Those who grow for exhibition will find it necessary to supplement the kinds named, or as many of them as they may choose, with a number that are less satisfactory in growth or do not flower freely. Bessie Brown, Dean Hole, Mildred Grant, Florence Pemberton, William Shean, Oberhofgärtner Terks and Mrs. J. H. Welch are among those best suited for this purpose. Though they cannot be called town Roses, these will yield some magnificent blooms if tended carefully; but many of them will show signs of going back, and it is necessary to replace such plants frequently. Many people like to have a few large bushes from which quantities of bloom may be gathered. The Bourbon Roses and their hybrids are excellent for this, the best being Zephyrin Drouhin, Mme. Isaac Pereire and Mrs. Paul Rugosas, of which the best is Conrad F. Meyer, also do well in towns, but the blooms are not lasting. The last named is a strong and vigorous grower, that is well adapted for training over a high fence where a screen is needed. The principal Hybrid Perpetuals for town gardens will be discussed in the next article, which will appear in the issue dated January 31st.

P. L. GODDARD.

ERODIUM TRICHOMANÆFOLIUM, A DWARF HERON'S BILL WITH WHITE FLOWERS AND CURIOUS SEED-PODS.

footstalk in such a way as to still point directly upwards, though distant from the unopened flowers by the length of the short stalk (usually about an inch), this leaving ample room for the later flower to expand. I imagine this curious movement (which is very decided, and in no way connected with drooping from the increasing weight of the fruit) is to displace the very large, spear-like seed-pods as far from the buds as possible, thereby preventing the latter from hindering the opening or pollination of the former as far as possible.

Owing to the beautiful downy character of the foliage of many of the *Erodiums* and their intense dislike of moisture about their crowns, it is advisable to place a piece of glass a few inches above them during our sodden winters, especially if the district is subject to fogs, which often bring down much dirt upon the plants.

R. A. MALBY.

Richmond should be in every garden. It grows freely, if not very vigorously, and flowers as continuously as any Hybrid Tea, which is saying a good deal. Unfortunately, it is rather subject to mildew, and the second and succeeding crops of bloom are apt to be of poor quality unless the plants are well looked after in the matter of feeding. Like Mrs. W. J. Grant, this is a Rose that requires and deserves extra nourishment. General Macarthur, almost equally free-flowering, has a sturdier growth and better constitution, but the bloom is not nearly so shapely. Neither can be called an exhibition variety, though Richmond occasionally produces a flower good enough to show. Avoca is splendid in colour, size and shape, and makes tremendous growth; but, unfortunately, it blooms but once. Every exhibitor should have it. Laurent Carle shapes well, but does not open freely enough, nor can it be called free-

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER CLIMBING ROSES.

REALLY good climbers are the scarcest of all Roses, and the hybridist has plenty of scope in this section. The really perpetual climbers are few and far between, and any new Roses that appear under this heading are apparently limited to climbing sports of the Hybrid Teas and Teas. They have the not inconsiderable drawback that every now and then they refuse to climb and revert back to the dwarf plants or parents. The wichuraianas provide us with most of our new climbers, and they are, for the most part, only seasonal flowerers, giving us a great show of blossom, it is true, but only for a few weeks of the year. Perhaps it will be convenient to deal first of all with the new varieties of this section.

Aviateur Bleriot (Fauque et Fils, 1910).—This is an excellent colour in the bud and young flowers that are produced in small clusters; but it is not, so far, with me a very strong grower, and would seem to be best fitted for a pillar or wall rather than for an arch or pergola. The foliage is pretty and persistent, but the flowers are only medium size, of a good saffron yellow, with a fair number of petals. I think I prefer both Shower of Gold and Klondyke to this variety.

Coronation (Turner, 1912).—This is a fine glowing colour, but the crimson-scarlet flowers are streaked or splashed with white; a very vigorous habit of growth, and the large trusses of flowers are very effective as seen from a distance. This Rose improves on acquaintance.

Ethel (Turner, 1912).—A semi-double flower of flesh pink shade. Like Coronation, this can be described as a very vigorous grower. It did not flower very freely with me last year; but perhaps it had hardly got established.

Klondyke (Paul and Son, 1911).—Pale primrose yellow flowers; but I shall be forgiven, perhaps, if I state that the beauty of the plant lies in the foliage. It is well worth growing for its foliage alone, and I can very strongly recommend it to all table decorators. I had to place an embargo on it in my garden, or there would have been no plant left. It has been described as an improved *climber*, but with me, so far, shows no signs of that Rose's vigorous growth. But here again it is, perhaps, hardly fair to form an opinion on one year's experience. There is no doubt, however, at all about the beauty of the plant

Southampton.

HERBERT E. MOLYNEUX
(To be continued.)

A NOBLE BORDER PLANT.

EREMURUS HIMALAICUS.

OFT and again the Eremuri have been recommended for grouping, and surely no greater tribute to their worth in that direction could be adduced than that afforded by the illustration accompanying these notes, which is from a photograph taken in Colonel H. Moore's garden at Higher Woodcombe, Minehead, Somerset. Of still greater

SEEDLINGS OF EREMURUS HIMALAICUS, THREE YEARS AFTER PLANTING, IN A SOMERSET GARDEN.

value, from the gardening point of view, is the fact that the group shown in the picture is still a youthful one, seeing that it was planted only three years or so ago, the plants at the time being seedlings of comparatively small size. Hence the picture demonstrates not only the value of grouping, but equally that of planting such things in the early stages of their existence. Then, from the suggestive standpoint comes the

important gardening lesson of all, viz. that we should raise seedlings of these things if our gardens are to afford us the picture groups these noble plants are capable of giving. Too often to-day, it is to be feared, the amateur ignores the seeds, the original clump continuing to yield but a tithe of the flower-beauty that might have been, had a few generations of seedlings been raised and planted from time to time.

It is not that we require them everywhere in the garden, so that the eye meets them at every turn, but rather that they should play their part alone—albeit boldly and in proportion to their merits—in shrubbery or sheltering bay, on the confines of woodland or park, or, indeed, any place where there existed a foil capable of throwing into fullest relief their unique beauty. In arranging such groups an item of the utmost importance is that of shelter—shelter, not so much from the winter's intenser cold, as from the ill-effects of nipping frost or withering blast of spring. Hence protection from north and east becomes a sort of necessity because of the early appearing of their somewhat tender leafage. In every other respect the plants are absolutely hardy; their great crowns might even protrude from the soil and suffer no injury in times of severest frost, though we are prone to give them a protective covering at such a time. The presence of a suitable foil as a means of reflecting the fullest beauty of these plants has already been remarked upon, though of not less worth is the surrounding greenery to their leafless flower-stems. Occasionally one sees these Eremuri rather closely associated with dwarf shrubs about their bases, and the idea may easily be carried to excess, to the detriment of both. Radiating like the spokes of a cart wheel from a common centre and somewhat shallowly placed in the ground, interference with the shrubs may cause serious mutilation to the roots of these plants. For this same reason of superficial root spread I am of opinion that the ordinary herbageous border is not quite the place for these Eremuri, though one sees them not infrequently so placed as isolated specimens. Such plantings, however permissible a decade or two ago, should find no place in gardening with these plants to-day, when, with fuller knowledge of them, they are worthy of the best the garden or woodland affords. A

peculiarity of these plants, in common with Asphodel, Anthericum and the like, is that they form crown upon crown to such an extent as to presently lift themselves to the surface, strong growing subjects like the Eremuri, because of their great crowns and thong-like roots, soon revealing their positions by the uplifting of the soil alone. The only remedy for this state of thing is replanting, which should be done in October

From the foregoing remarks it will be noted probably that a greater superficial area of soil rather than a great depth is necessary for these plants, and the deduction would be fairly correct, though soil depth must not be ignored. In planting the Eremuri it is well to remember that in flowering they afford a succession for some weeks, the white-flowered kind so well portrayed in the illustration being one of the earliest, and Shelford, Warei (bronzy orange) and Bungei (yellow) appearing at the other end of the chain. In any attempt to raise seedlings, the important fact should be remembered that seeds soon lose their vitality; hence it would be prudent to sow the seeds a few weeks after maturing. It would be well, too, to make the sowing in a frame, and sufficiently thin that the seedlings may remain to their second year, always transplanting them in autumn when dormant.

E. H. JENKINS.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

(Continued from page 19.)

Propagation.—Many people are at sea regarding the propagation of hardy border flowers. The division of old plants and the raising of new stocks from seeds comprise the sum of their knowledge. Even such a simple operation as division has its variations. A spade, or two forks in the hands of the less clumsy, does not include all, for there are numbers of plants which give of their best only when divided carefully into very small portions. The better species of *Aconitum* should be annually divided into single crowns, the best selected and planted singly, according as they are wanted, in clumps, when 4 inches to 6 inches apart is a proper distance, or, if mixed with other plants, spaced to suit these. *Senecio tanguticus*, *Helianthus D. Dewar* and *H. Miss Mellich* should be treated in the same manner, allowing wider spaces, the first named at a foot apart being none too little. Similar treatment suits some of the fibrous-rooted section. Surely no plant is more ugly than the double *Rudbeckia laciniata* grown with many stems together and these tied to a stake, with the heads of its lovely golden flowers drooping as if ashamed of their plight. But plant these singly a few inches apart, and the need of support of any kind, as in the case of many other plants given a like treatment, is done away with, and its full beauty is displayed without any drawback.

The varieties of *Chrysanthemum maximum* afford examples of subjects which may be planted singly—just slips with one growth and a few roots to start them with, or larger pieces with several growths. These grow tall, and need support of some kind to keep them from sprawling over the border. The first named, on the other hand, are comparatively dwarf, need no stakes, and produce a broad mass of bloom of equal height. Nine inches apart is as wide as they should be arranged. *C. uliginosum* is best treated in much the same way, only the pieces must be set much closer. Several *Asters* succeed best from single growths planted close together, the *Novi-Belgii* section more particularly, also *puniceus* and *corymbosus*; but the varieties of *viminialis*, *ericoides*, *acris*, *Amellus* and *Linosyris* should have a few growths each and be planted a little wider apart. *Rudbeckia speciosa* should be annually

transplanted, but not in single growths, only the divided pieces when planted must be touching each other to afford the best effect.

Varieties of *Anthemis tinctoria* give much the best results when replanted annually, but, instead of rooted pieces, cuttings should be inserted in the autumn in a frame and transplanted in spring. These are quite as floriferous as old plants, but grow not nearly so tall, the one fault of the latter. *Erigeron* does best pulled into small pieces and planted close enough to meet when in flower; *E. mucronatus*, either from cuttings or seeds. *Nepeta Mussinii* is always best from cuttings in autumn, and so is *Pentstemon heterophyllus*, as a rule. *Phloxes* should not be over-propagated. New varieties are easily increased from root cuttings, and older ones from stem cuttings; but usually for decorative effect a plant with several stems, though the heads of bloom may be smaller, is to be preferred to the smaller ones.

Raising Plants from Seeds.—Quite a number of useful plants can be raised from seeds. Such

PROPAGATION OF HERBACEOUS PLANTS.

A—Slip of *Solidago*, *Aster*, &c., for planting close to form a mass. B—Root cutting of *Verbena venosa*. C—Root cutting of *Phlox*. D—Eye cutting of *Hollyhock*; many herbaceous plants are increased in this way. EE—Roots of *Aconitum*; plant 3 inches deep. The bars represent the soil level.

are *Delphiniums*, *Lupines* and *Agapanthus*, but the seedling *Agapanthus* must be grown on in pots till they have attained flowering size. *Heucheras*, *Dictamnus Fraxinella*, *Centranthus ruber*, *Hollyhocks*, *Isatis glauca*, *Dianthus* species, *Papaver rupifragum*, *P. pilosum*, *Gladioli*, *Sea Hollies*, *Tritomas* and *Scabiosa caucasica* constitute a selection. The double forms of *Hesperis matronalis* may be propagated either from pieces of the stems in summer or from the little root growths, which should be kept in a frame during the winter. These make the best plants. *Lychnis*, *Hollyhocks* and many other plants may also be increased from the stems, cut into short pieces. From pieces of the roots *Verbena venosa*, *Romneya Coulteri*, *Anemone japonica*, *Anchusa*, suffruticose *Phloxes* and *Oriental Poppies* are easy of increase. There is also a class of plants which, once established, may be left indefinitely without lifting and dividing. Examples of such are perennial *Statice*, *Spiraea Aruncus*, herbaceous *Pæonies*, *Tritomas*, *Helleborus niger* varieties, *Anemone japonica*, *A. angulosa*, *Dictamnus Fraxinella* and *Astilbe rivularis*. *Pinks*, *Sweet Williams*, and some of the *Mule Pinks* may be pulled to pieces in

September and the stems inserted in the ground, and all will make nice flowering plants the succeeding year.

Some perennials flower the same year if raised early and started in heat. Such are *Delphiniums*, *Lupinus polyphyllus* in variety, *Scabiosa caucasica*, *Cheiranthus*, *Pentstemons*, *Daisies*, *Chrysanthemums*, *Verbenas* and *Antirrhinum majus* varieties. These and others similarly produced are very valuable for autumnal effects, and, in a word, many plants may be increased from seeds with the greatest advantage. A few biennials are especially valuable. Such are *Campanula pyramidalis*, *Gilia coronopifolia*, *Foxgloves* (the white especially), *Canterbury Bells*, *Sweet Williams*, *Hesperis matronalis* (the single varieties), *East Lothian Stocks* in mauve, crimson, purple and white, *Lychnis Agrostemma* and *Columbines*. Some of these assume a perpetual character, but on the whole young plants are the more effective.

Of Annuals the number that may be used is very large, some hardy, others tender. The greater part of the last named I raise on beds of soil in cold frames, the seeds being sown early in April and afterwards pricked out into beds in reserve, to be transplanted in autumn to fill vacancies caused by the earlier plants which have done blooming. The best of these are *African Marigolds*, the doubles being separated from the singles when in flower and arranged in masses of a colour. Few autumnal flowers are more gloriously beautiful than these. The dwarf forms are usually planted in June where they are to flower, as also are *French Marigolds*, of which the deep browns, both dwarf and tall, are very effective. *China Asters* are treated in much the same manner, some being kept in reserve, others planted at once. *Dobbie's Quilled* and *Ostrich Plume* are the two sections I prefer. The old, tall *Ageratum mexicanum* gives good results if raised in heat annually. Other good annuals are *Lobel's Catchfly*, *Statice sinuata* (white and mauve especially) and *S. Suworowii* (finer than *S. spicata*). The tall form of *Alonsoa Warscewiczii* is very brilliant. *Love-lies-bleeding* and *Prince's Feather* should be sown either under glass or late in the open. The crimson-leaved form of *Atriplex hortensis* is indispensable, as also is *Kochia tricophylla*.

To these should be added *Stock-flowered* and *Emperor Larkspurs*, which are sown in boxes and germinated in heat to secure an early start, the seedlings being dibbled into their places when quite small or before the tap-roots have been formed; *Lavatera rosea* and *Clarkia elegans* (double) in various colours; *Brachycome iberidifolia*, of which white is the best; common *Marigolds*, *Anagallis grandiflora*, several *Chrysanthemums*, *Convolvulus tricolor*, *Dianthus Salmon Queen*, *Godetia Schaminnii flore pleno*, *Matricaria Golden Ball*, *Nemesia* in great variety, *Nigella Miss Jekyll*, *Saponaria calabrica*, *Scabious*, *Tropæolum aduncum*, *Xeranthemum annuum* and *Virginian Stock*. This is not an exhaustive list, but all those named possess much merit as border plants.

Prestonkirk, N.B.

R. P. BROTHERSTON.

(To be continued.)

LARKSPUR SEEDLING, SHOWING STAGE OF GROWTH TO PLANT.

THE TRAINING OF WALL FRUIT TREES.

CORDON fruit trees become increasingly popular each year, and the reason is not far to seek, for such trees are easily managed, while space is economised to the greatest extent.

The early training of the trees is usually carried out in the nursery, and when the cordons leave the nursery they should not only possess main stems as straight as gun-rods, but also be furnished almost to the ground-level with fruiting spurs. If good trees are procured from the nursery in the first place, it then requires only common-sense methods to retain those trees well trained in one's own garden. Speaking generally, cordons should be planted obliquely. The reason for planting them on the slope is that a greater extension can be given to the leaders, which should not be carried above the top of the wall. Vertical cordons should only be placed against high walls or pillars, and even then over-vigorous varieties should not be planted. A point worth noting in planting cordons is that the more pronounced the incline, the further apart should the trees be placed. Double cordons or U-shaped trees are sometimes preferred, and occasionally one sees a wall planted with triple cordons; but for all practical purposes the single cordon gives the best result. Horizontal cordons, with low branches about one foot from the soil and trained parallel to the ground, are favoured for forming edgings to borders. Growth, however, is so restricted that trees trained in this manner rarely live for very many years. Slow-growing Apples on Paradise stock are best suited for horizontal cordons. The horizontal trained tree, with branches arranged tier upon tier, is one of the best forms of trained trees for planting against walls. Should the branches on one side of the tree grow at the expense of those on the opposite side, the vigorous branches should be tied down temporarily. This will weaken them, while the weak branches may be strengthened by being raised. Much may also be said in favour of the fan-trained tree, particularly with such fruits as Morello Cherries, Peaches, Nectarines and Apricots. The illustration on this page depicts a fan-shaped Pear which, it should be noted, is splendidly furnished with fruiting spurs. The Pear, however, is one of the easiest trees to train, and will do equally well as a cordon, either single or double or horizontally trained. Another type of wall tree worthy of note is the trained standard fan. Obviously it is only suited to very high walls or buildings. On the Continent it is regarded as a lucrative way of covering the upper part of one's house.

Apples, Pears and Plums.—In pruning trained trees the object should be to make every branch a cordon, with fruit spurs along the entire length of the branch. "Once a fruit spur always a fruit spur" is an old saying among fruit-growers. In order to secure fruiting spurs it is necessary to prune hard the second season after planting, and the following season the resultant vigorous growth should be shortened to about one-third its length. Summer pruning is important. It is accomplished by pruning or pinching back lateral growths to the extent of about 4 inches in July. It should be annually followed by winter pruning, when the side growths are cut back to two or three eyes. The fruiting spurs should, of course,

never be pruned. With horizontal trained trees the leader should be cut back to within a foot of the top horizontal tier, and with cordons it may be shortened in proportion.

Peaches and Nectarines.—Unlike the Apple and Pear, these trees fruit upon the young wood, and not on fruiting spurs. The main shoots should be shortened about one foot in winter, and overcrowded growths thinned to the base. The young or fruiting wood should be retained and laid in on the upper side of the leaders only. This will ensure uniformity in fan-shaped trees and avoid the crossing of branches.

Gooseberries and Red Currants.—These fruits give capital results if trained as cordons. The terminal or leader should not be shortened except to keep the cordons within bounds. All side growths should be pinched back to three eyes in the summer.

Aspects for Fruit Trees.—Pears, Plums, cordon Apples and dessert Cherries may be given

trees against walls, the base of the trees should be brought about 10 inches forward away from the wall.

WHY SEEDS SOMETIMES FAIL.

OF course, bad seeds will not germinate under any treatment. Sometimes, however, good ones fail to do so, even when every convenience exists for their proper treatment. There are several causes for failure, namely, sowing too deeply, not deep enough, a too wet soil, and also a too dry one. Now, to be successful, the reader will at once think that the happy medium must be secured in each case. If it is, there will not be many failures; but with a certain amount of moisture we must also have heat. If seeds are sown in a very cold soil at this season, many may perish in it, especially if the soil be very wet. Seeds of the more tender kinds of plants require a warmer temperature than those of hardier kinds. Example: Cucumber seeds would decay

A WELL-TRAINED FAN-SHAPED PEAR TREE. NOTE THAT EACH ROD IS FURNISHED WITH FRUIT SPURS.

either easterly, westerly or intermediate positions. Morello Cherries and certain Pears do well from north to east, and the same aspect may be given to Gooseberries and Red and White Currants. Apricots, Figs, Nectarines and Peaches should be given a westerly to southerly position.

Planting.—The work of planting is best carried out in the autumn, but it may be successfully accomplished at any time when growth is dormant, providing, of course, that the weather is open and that the soil may be readily worked. It is a common mistake to over-manure the soil at the time of planting. Providing that the soil has been previously worked, very little, if any, manure need be applied, and even then only well-rotted manure should be incorporated with the soil. In cases where the soil is deficient in lime, the addition of a little lime rubble around the roots of each tree will prove highly beneficial; in fact, the value of lime rubble for fruit trees generally cannot be overrated. When planting trained

in the soil if given similar conditions to those of Broad Beans, but the latter would germinate quickly if treated the same as Cucumber seeds. In very hot weather—in summer-time—it is absolutely necessary to give seeds a moister soil than in January, February and March. Dust-like seeds—those of Begonias, for example—should be sown on a moist surface where coarse sand is plentiful. Celery seeds should have a quarter of an inch of fine soil evenly scattered on them; Cucumber seeds require nearly an inch of soil; Peas rather more; Broad Beans quite 2 inches; and so on. The soil must be maintained in an even state of moisture. Many cultivators cover the seed-vessels with glass and paper. If the covering is removed in good time, the young seedlings will not be damaged; but if left on too long—even a day in some cases—the seedlings are much weakened and often die afterwards. Never sow thickly, as crowded seedlings are always weakly.

SHAMROCK

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Peach Trees in late houses should be prepared for forcing with as little delay as possible. In pruning the trees all gross shoots that can be spared should be cut away, leaving the medium wood with a space of at least 4 inches between the shoots when tied, for it must be remembered that at least one young shoot will have to be tied into each space before the season is very far advanced. If the trees are infested with any insects, they must be carefully washed with a solution of some approved insecticide. The borders should be examined, and if the roots are near the surface, a sprinkling of bone-meal may be applied previous to a top-dressing of loam and old lime rubble. If the border is dry, water should be given in sufficient quantity to reach the extremities of the roots.

Late Vines.—Any Grapes that remain on the Vines should be cut and placed in the fruit-room, where they may be kept in good condition for several weeks. The ventilators should then be opened and the Vines pruned as soon as possible. Remove all loose bark without breaking the inner bark, and if mealy bug is present on the Vines, they should be carefully washed with Gishurst Compound and warm water. At the same time the interior of the vinery must be thoroughly cleaned. If any additions to the borders are contemplated, these should be made at once. It is better practice to make small additions to the border each season than to place a large quantity of soil in the house at one time, as this may become sour, and consequently the crop will be unsatisfactory.

Plants Under Glass.

Roses in pots should be pruned now and placed in a temperature of 45°. The crocks should be examined so that the water may pass freely from the pots, and, if necessary, a top-dressing of rich loam and lime rubble should be applied. If a constant supply of blooms is necessary, a few fresh plants should be introduced to heat every ten days. Good drainage and careful ventilation are of the greatest importance.

Cannas.—Old roots of Cannas may be shaken out and repotted in a compost of rich loam and thoroughly decayed cow-manure. They may be started into growth in a temperature of 60°. Seeds may be sown now in small pots for flowering the following season. These seeds are slow to germinate, and may be soaked in water with a temperature of 90° for twelve hours previous to sowing.

The Conservatory.—Various flowering shrubs should be in readiness now to take the place of Chrysanthemums. Many of these are easily forced, and may be had in quantity, providing a reserve plot is available to grow and prepare them during the summer.

The Flower Garden.

Taking Cuttings for Summer Bedding.—Such plants as Heliotrope, Verbena, Ageratum, Coleus, Lobelia, &c., may be increased to what is necessary by taking cuttings now, providing a hot-bed is available for the purpose.

East Lothian Stocks.—Now is the time to sow seeds of these lovely Stocks in order to have a display of flower in the early summer. These are frequently sown in March, when the plants do not flower till September. Cover the seeds lightly, place them in a temperature of 60°, and pot up the seedlings as soon as large enough to handle. By this means good, strong plants should be ready to put out in April.

The Hardy Fruit Garden.

The Pruning of Peach Trees.—Much of the work in this department will depend on the weather. While fine, the pruning of Peach trees should be persevered with, and while this work proceeds the whole of the branches should be detached from the wall and the old shreds burned, as they may contain the eggs of some troublesome insect. As the shoots are being replaced on the wall, a space of several inches should be allowed between them in order to admit of the laying in of next season's growth.

Raspberry Shoots may be thinned and tied to the wires at any time, providing the ground is not too wet. This is a surface-rooting plant, and requires a rich, open soil to grow it to perfection. If the soil is of an open nature, a top-dressing of manure may be applied as soon as tying is finished. If the ground is heavy, the top-dressing may be deferred till March, but the surface may be lightly broken up and exposed to the weather.

The Kitchen Garden.

Lettuce in cold pits should be freely ventilated when external conditions will permit. Stir the soil among the plants and remove all decaying foliage. Dampness is the worst enemy to all salad plants in winter. A sowing of Lettuce seed may be made in boxes, and the young plants pricked into a cold pit as soon as large enough to handle.

Early Broccoli in the open garden should be carefully protected from frost. As soon as the heads appear, the plants may be lifted with a good quantity of soil and placed in any cool structure with plenty of light.

French Beans.—A sowing of these may be made now in 7-inch pots and placed in a temperature of 60°. Pods should be ready to gather within seven weeks from the time of sowing.

Mustard and Cress should be sown weekly and placed in any forcing house or pit with a temperature of 50°.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Wood-Ashes.—Collect and burn all prunings and other garden rubbish and store in a dry shed; in fact, there should be little or nothing to cart away from any garden. Hedge-trimmings collected and burnt make an excellent top-dressing; indeed, one should always be on the look-out for all burnt refuse, as this is invaluable in preparing ground for Onions and Carrots.

Pea-Sticks.—In wet and frosty weather Pea-sticks should be gone over, sharpened and graded in different sizes. By no means destroy small branches of these, as they are very useful for supporting the smaller-growing herbaceous plants, besides being less unsightly than the ordinary garden stakes.

Early Carrots and Turnips.—Where early Carrots and Turnips are in demand, now is the time to make up hot-beds. For this purpose the best material is leaves and stable litter, about two loads of the former to one of the latter. When the bed has had time to settle, a small sowing may be made of Carrots, Turnips and Radishes. These are greatly appreciated even in a very young state.

Parsley.—As Parsley takes some little time to germinate, a sowing may be made now, so as to be ready for planting out about the end of March.

Early Potatoes.—A few early Potatoes may now be planted in slightly heated pits. I find Sutton's May Queen an excellent variety for this early work. Great care will be necessary to protect the young growths from late frosts, but at the same time avoid coddling.

Globe Artichokes.—These require to be carefully protected during this month, particularly against damp. I find the best material for this is engine ashes, not too new. Mound them up well round the crowns, and the possibilities are no other protection will be required.

The Flower Garden.

Alterations.—The weather during the late autumn and early winter was the mildest experienced for very many years, and, in consequence, those who had alterations to make on lawns or grass paths had an exceptional opportunity of forwarding that work. Should any, through stress of other duties, still have some turfing to do, no time should be lost in completing it. The present is a good time to attend to defective drains and all work that requires serious disturbance of the paths and lawn.

Rhododendrons that do not seem to be particularly happy in their surroundings will, in many instances, be greatly benefited by a good mulching of farmyard manure. Many recommend spent Hops and leaf-mould, which are doubtless good in their way; still, I have not seen anything to equal the manure. When the variety Pink Pearl was introduced, I planted a number in a cold district in the North. For a time they seemed only to exist, and, alarmed at the price paid and the consequences of failure, I sought the advice of an experienced grower. His advice was, "Try farmyard manure," which I did, and the result was beyond my utmost expectations.

Helleborus.—Where Christmas Roses are grown in quantity, a number of clumps should be protected by hand-lights, which will not only improve the flowers, but will draw out the stalks and make them more useful for decorative purposes. A few roots may be lifted, placed in cutting-boxes, and brought on in the propagating-pit.

Carnations.—During severe weather border Carnations should be protected against rabbits and voles, which are very destructive to Carnations. Even in walled gardens it is surprising how the pests find their way in. In most cases carelessness in leaving doors and gates open is responsible for their presence. To protect Carnations against such foes, a remedy I have found most effectual is to saturate string with Renardine and stretch it along the outside of the border about six inches from the ground. Support the string with small stakes, and paint it over from time to time with this mixture.

Hardy Fruit.

Gooseberry and Currant Cuttings.—Where it is intended to increase the stock of Gooseberries and Currants, suitable cuttings should be selected from the prunings. These should be straight and of a fair thickness. When the weather is such as to prevent work being done out of doors, these cuttings may be made, correctly named, tied into small bundles, and heeled in until they may be planted.

Protecting Fruit Trees.—Plantations of Apples and Pears (indeed, of all hardy fruit trees) should be guarded against rabbits and hares, especially in frosty weather. Quite recently I saw great destruction done during a storm, wall trees being barked up to 2 feet from the ground. The Renardine recommended for border Carnations will keep them at bay. In the case of fruit trees, string will not be necessary. I simply smear the foot of the stem with the mixture.

Fruits Under Glass.

Strawberries.—Early forced Strawberries will now be in flower. Go over them carefully with a rabbit's tail to ensure a good set. The atmosphere may be kept somewhat dry, but all possible means should be taken to keep down red spider, which soon makes its appearance on early forced plants.

Vineries.—Vines that were started about the New Year will be beginning to move, and the greatest precautions will have to be taken in admitting air at this stage. The sun may be shining brightly during the middle of the day, and yet the air outside be extremely cold. An increase of 5° in the temperature may be allowed. In starting Muscats I believe it is an excellent plan to top-dress the inside border with a little hot-bed material; this encourages the roots to start and has a tendency to keep them near the surface.

Melons.—Where Melons are required in May, a small batch should be sown now. Unless in very favoured districts, the early lot of Melons will cause a good deal of worry before they reach the ripening stage, chiefly through the lack of sunshine. They succeed best in a good, heavy loam mixed with a little lime rubble. Where one has any doubt of the suitability of the soil for this or other crops, he should have it analysed, which will prevent many failures.

Cucumbers.—If a sowing of Cucumbers has not been made, no time should be lost in making a start, as a few early Cucumbers are almost indispensable for the beginning of the salmon season.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)

Hoptoun Gardens, South Queensferry, N.B.

RENOVATING OLD GRAPE VINES.

A GOOD many gardeners seem to think that when once Vines begin to show a falling off in the size of bunch or berry, the only thing to do is to root them out, make a new border, and replant with young rods. This I consider an entirely wrong course to pursue, unless, indeed, the Vines are very far gone. From a fairly long experience I have learned that even quite aged Vines can be brought back to a state of usefulness if only the right method be adopted. When serving my apprenticeship—now a good many years ago—a large vinery in the gardens where I was employed got into an unsatisfactory state, and there was talk of having all the Vines rooted out and new ones put in their place. The head-gardener, however, saw that there must be a shortage of fruit for two or three years if this plan were adopted, so, instead of this drastic measure, proceeded to rejuvenate the old Vines, which must at that time have been thirty years old. This was done, and with the most gratifying results.

Some years later, on taking charge of a garden in the South of Scotland, I found two vineries in a deplorable state. For some unexplained reason my predecessor mulched the outside border each autumn with 6 inches to 9 inches of farmyard manure, and this was never removed. The result was some 9 inches of solid, rotten manure over the whole border. In wet weather to step on the border was like going on to a morass, and, as may be supposed, the sun's warmth never got near the roots. While the Vines were certainly planted inside, the great bulk of the roots had to go outside, the inside border being only 18 inches wide.

The Plan of Renovation.—During the winter I got together a large quantity of excellent fibrous turf, lime rubbish from old buildings, bone-meal and Thomson's Vine Manure. Early in February, the weather being suitable, I started to overhaul the whole border. First I removed the whole of the manure down to the soil, as it was worse than useless for my purpose. Then, starting at one end, I took out a trench 5 feet or 6 feet wide, and extending from the vinery right to the walk. Any roots found near the surface were mostly dead, so these were, of course, cut away. After going down about a foot or fifteen inches, a few live roots were found, and these were very carefully preserved. After going to this depth I could see that there was nothing wrong with the drainage, so concluded I had gone deep enough. I then spread a good layer of the turfy loam in the bottom of the trench, mixing with it a generous quantity of lime rubbish and bone-meal as it was wheeled in. (It saves time and labour to mix the ingredients as they are being used, and is quite as satisfactory in the end as mixing all together in a heap.) The roots were then laid out at full length on the new soil, and a notch made at every 9 inches to 12 inches on the under side of the large thongs. To induce the early formation of fibrous roots, a handful of fresh, light compost was placed round the roots where the notches were made. More fibrous loam, lime rubbish and bone-meal was laid over the roots, and well firmed by beating with a manure fork. A fair dressing of Thomson's Vine Manure was applied to the surface, and then 3 inches of the best of the

old soil from the second trench spread over all. This completed the first trench, and the whole of the border was treated in the same way.

Subsequent Treatment.—That season I kept back the starting of the Vines for three or four weeks, and brought them on very gradually. I also cropped rather lighter than usual, and even the first season saw considerable improvement. After the Grapes were thinned and swelling rapidly, the border got another light dressing of Thomson's Vine Manure, which was hoed in. In the autumn the border was mulched with 9 inches of fresh stable litter, and this was removed about the end of March. A fairly generous sprinkling of the artificial fertiliser already mentioned was again given and lightly forked in, while, after thinning, a rather lighter dose of the same was applied. These two dressings and the food washed from the mulching was all the feeding given, and the results were so gratifying that I would never hesitate to repeat the cure should unsatisfactory Vines come my way again. During three or four subsequent years I gave the same two dressings of artificial manure and the autumn mulch of stable litter, and the Grapes improved so much in that time that I was able to take first prize for Hamburgs at the Edinburgh Autumn Show. It may be of interest to state that these Vines, when I took them in hand, were at least forty years old.

Treatment of the Rods.—As may be supposed, most of the Vines carried very long, unsightly spurs, and, as far as I could see, the original rods had never been renewed. In a few cases I noticed buds low down on the stems; these, of course, were very carefully preserved. In due course the resulting shoots formed strong rods, which eventually took the place of the old ones. To ensure no loss of crop, I cut away only part of the old spurs on one side of the old rods to make room for the new growths, but in the end sawed away the old canes as low down as possible. The rods that failed to produce buds from the stem had to be worked by choosing a suitable shoot from the lowest spur, and these also turned out well. While February is a good time for this work, providing the Vines need not be "started" till March, very early houses should be attended to in October.

Preston House, Linlithgow.

C. BLAIR.

THE EDITOR'S TABLE.

Darwin Tulips for the New Year.—One of the most interesting contributions to our table that we have received for a long time consisted of three full-blown plants of Darwin Tulip Wm. Copeland, the colour of which is a charming shade of lavender mauve. These were sent on January 3 by Messrs. de Graaff Brothers, Limited, of Leiden, Holland, and were perfect plants. The following particulars were also kindly sent by Messrs. de Graaff: "To-day we have sent three plants of Darwin Tulip Wm. Copeland. The bulbs were brought in a temperate house on December 1, where the temperature never exceeds 70° Fahr., and we picked the first flowers on December 27. We are certain this variety can be brought into flower in any ordinary greenhouse from January 1 to 15 quite easily and without any extra care or trouble. We thought this might interest you, as we do not believe there is another Darwin Tulip that can be had in perfect condition at such an early date."

GARDENING ACROSTICS.

DOUBLE ACROSTIC No. 7.

I grow among the loose *débris* of British mountains.

Firsts.—My botanical name written thus:
A. rosea.

Lasts.—A kitchen garden herb, which I resemble.

1. Sometimes a ball, sometimes wine.
2. A Roman writer of the first century on horticulture.
3. A mite that loves dryness and hates damp.
4. The generic name of an old-fashioned garden or greenhouse annual once very popular. Its flowers are like small Camellias.
5. "Non rego, nisi regar." On what might this motto be appropriately placed?
6. Connected with Price.
7. "An ignorant conceit," as Bacon called it, for plants growing "worse" when planted together.

Solutions of the foregoing must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, January 24. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 5.

FORSYTHIA—SIEBOLDII.

* 1.	F	UCH	S
† 2.	O	LEARIA HAASTII	I
‡ 3.	R	OWAN TRE	E
§ 4.	S	U	B
5.	Y	ELLOW NELUMB	O
¶ 6.	T	REFOI	L
** 7.	H	YBRI	D
†† 8.	I	RIS KÆMPFER	I
‡‡ 9.	A		I

* Leonhard Fuchs, born 1501, was one of the fathers of German botany. He published his herbal, "De Historia Stirpium," in 1542. The illustrations in outline are beautifully executed.—See Arber's Herbs. † Olearia Haastii is an evergreen with small, Daisy-like flowers opening in autumn. It is hardy in most places in the open.—Nicholson's Dictionary of Gardening. ‡ One derivation of the Rowan-tree (*Pyrus Aucuparia* or Mountain Ash) is from the Scandinavian "Runa"—a charm.

"Roan-tree and red thread

Haud the witches a' in dread."

—Friend's "Flowers and Flower Lore."

§ "Sub," as a botanical prefix to words, signifies "nearly," "slightly" or "somewhat," e.g., subrotund means roundish. || The yellow-flowered Nelumbo is a sacred flower in China.—Friend's "Flowers and Flower Lore," page 459. ¶ The Trefoil or Shamrock, which in very remote times was considered to be a charm against witches. It was plucked by St. Patrick as a means of illustrating the doctrine of the Trinity. It is now the national emblem or symbol of Ireland. ** A hybrid is a cross between two distinct species of the same genus. It is very often wrongly used to denote a cross between two varieties of the same species. †† Gauntlets, in their large catalogue No. 93, designate Iris Kämpferi "The King of Irises." ‡‡ The letters A I are supposed to be visible on the petals of the Hyacinthus or Eastern Hyacinth, but to be wanting on our Wood

Hyacinth, *Hyacinthus non-scriptus*. — Friend's "Flowers and Flower Lore," pages 384-85.

RESULT OF ACROSTIC No. 5.

Eleven marks were possible in this acrostic, one for each correct "first" and "last," and one for each correct light. The following marks have been awarded:

Eleven marks.—"Hero."

Ten marks.—"Rusticus," "Westbank," "Jan," "Bow," "Ping" and "Rustic."

Nine marks.—"Nautilus," Ernest Ballard, M. Browne, "Penwarne," "White Lady" and "Elm."

Eight marks.—"Miller," "Tempus Fugit," "M. M.," "St. Kevin's," "Boatsvale," R. Chapman and "Scotia."

Seven marks.—"Brixtonian," G. D. King, "W. R. D.," "Johnny Crow," "Judith" and "W. J. W."

Six marks.—"Shamrock" and A. Henderson.

Four marks.—N. G. Hadden.

Three marks.—Wm. Slocombe.

Two marks.—A. D. Morris.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET WILLIAM RUST (S. W. H.).—Puccinia dianthi, the Sweet William rust, is attacking your plants. You are quite right in taking and burning the diseased ones, and it would be well to spray the others with a rose red solution of potassium permanganate as a means of checking the spread of the disease.

VIOLETS FOR MARKET (E. G. W.).—The best selling Violets are de Parme, La France, Princess of Wales and wellsiana, the first named having double flowers. La France and Princess of Wales are large-flowered, long-stemmed varieties, wellsiana being smaller, shorter-stemmed and more free. The correct method of increase is by unflowered cuttings, making a beginning in early autumn with the runners, usually plentiful at framing-time. By inserting these in sandy soil in shallow boxes, excellent plants for putting out in April would result. Any runner growths produced during the winter would also be serviceable as cuttings. Divided plants from stock plants that have flowered for months are valueless by comparison, though they are useful occasionally for producing cuttings when they have fully recovered.

LILIUM AURATUM (L.).—Your success with this somewhat fastidious plant is most encouraging, and instances of it becoming permanently established are by no means common. In these circumstances it is desirable to do the best possible for it, and as you have to move it, we suggest the work be performed now. You had better replant it outside, giving it conditions as nearly identical as possible to those in which it has been so great a success. The bulbs will now have many basal or main roots, i.e., those below the bulb, and these, being of vital importance, should be preserved intact, and in the replanting spread out thinly—not doubled up in a mass below the bulbs. The stem roots, those on the old flowering stem, having completed their life's work and being, like the flower-stem, of annual duration only, can be removed close to the bulbs, in which position a richer supply of food will be of assistance to the new roots formed in the present year. We think it right to warn you that this replanting of established clumps may mean a loss of stature—possibly also of flower-buds to some extent—in the first year, though the check, if the work be intelligently done, should not be half so great as if

performed in spring, when growth will be more forward. Potting them up would most likely mean failure, and is not to be advised.

PAVING STONES (R. G., Woking).—So far as we are aware, there is no artificial paving that comes cheaper than natural stone. The cost of a broken or "rustic" paving at your station would probably be about 26s. per ton, carriage paid. One ton would lay down about ten superficial yards. For paths in the kitchen garden or in out-of-the-way portions of the grounds, we have seen paths made of concrete, 1½ inches to 2 inches thick of coarse concrete covered with three-quarters of an inch to 1 inch of fine concrete. The surface is ruled with the same joints one would get with rectangular paving. The ruling is done with the point of a trowel and straight-edge. Brick paths are less expensive than paving, and if the joints are of earth, and fine grass allowed to grow, are really picturesque, especially when in conjunction with brick buildings. Grey granite chippings make an excellent path, providing a good foundation is made before they are put down. They can be kept rolled or raked, according to taste, and the cool grey is a desirable colour in the garden.

PLANTS FOR CLAY SOILS (E. P.).—The most effectual, and possibly also the cheapest way of improving such soils is winter trenching—throwing the soil high into rough ridges—and incorporating lime in considerable quantities at a depth of 18 inches as the work proceeds. The ridging exposes a greater superficial area to the action of fresh air and tends to drain the soil, while the lime, by coagulating the particles of the soil, precipitates the water to a lower level, thereby warming, aerating and draining it as by a single action. Unless you are prepared to improve the soil in some such way as this, we are afraid you will have to be content with a modified success. You would also find spring planting of assistance in the case of the doubtful ones. The best herbaceous perennials for heavy soils are Pæonies, Flag Irises, Michaelmas Daisies, Kniphofias, Trollius, Spiræa, Heleniums, Helianthus (Sunflower), Astilbe Davidii, Anchusa, Phlox (herbaceous kinds), tall-growing Achilleas, Campanulas, such as van Houtte, all the persicifolia varieties, latifolia, lactiflora and carpatia in variety; Aster Amellus, Delphiniums, Lupinus polyphyllus, L. albus, Galegas, Japanese Anemones in variety, Oriental Poppies, Hemerocallis or Day Lily, Double White Rocket (Hesperis matronalis flore pleno), Hollyhocks, Cimicifuga, Sedum spectabile (in opposition to the general belief), Potentillas, Lychnis chalcedonica, Solomon's Seal, Megasea cordifolia purpurea, Lenten Roses, Pinks and Aubrietias. Such Lilies as Liliun umbellatum, pyrenaicum, croceum, Martagon and chalcedonicum are usually a success. Pentstemons would do if planted annually in spring, and, while affording good colour, assist by their comparative dwarfness.

TREES AND SHRUBS.

TO GET RID OF ELDER TREES (Junius).—Give the roots of the trees a good soaking with weed-killer or double the usual strength. This will kill them.

EUGENIA BERRIES (S. S.).—The fruits of Eugenia Ugni are used for culinary purposes in their native country. The plant is referred to as follows in the "Treasury of Botany": "Its fruit is highly esteemed in Chile. Those grown in this country are glossy black when ripe, and have an agreeable flavour and perfume." Their best use in this country would probably be for making into jelly.

EVERGREEN SHRUBS FOR HEDGE (New Reader).—The common Holly is the best evergreen you can procure for the position mentioned. Another suitable shrub is Berberis stenophylla. This is a free-flowering evergreen, but it is inclined to grow rather wildly and requires more attention to keep it in good condition than the Holly. If you select Holly, you had better not plant the hedge before April.

TO PRUNE WEIGELAS (Burton).—The young Weigelas ought to have been pruned rather severely during the first two years of their life. Much pruning would have prevented them from becoming straggly. As it is, you had better wait until after they have flowered in May, and then cut them fairly hard back. If you do not mind losing the flowers, the pruning may be done in February or March. This would give a longer growing season.

WISTARIA CHINENSIS AND ITS SYNONYMS (C. S. J.).—The plant to which you direct attention is named, correctly, Wistaria chinensis, but, as is the case with many other plants, different botanists have at various times placed it in other genera, and it has at one time or another been known both as Glycine sinensis and Milletia chinensis, names which are still occasionally used. As mentioned above, the correct name is Wistaria chinensis, and as such it is generally known.

FLOWERING EVERGREENS FOR SMALL GARDENS (Lion).—The following shrubs are likely to suit your purpose: Laurustinus (Viburnum Tinus), white, winter and early spring; Berberis Darwinii, orange, April; B. stenophylla, orange, April; Choisya ternata, white, May; Escallonia langleyensis, pink, June to August, sub-evergreen; Cotoneaster microphylla, white, May; Rhododendrons in variety, Ericas in variety and Pernettya mucronata. If the soil does not contain much lime, Hypericum calycinum, yellow, summer; and Berberis Aquifolium, yellow, March.

CORONILLA (Miss E. A. M. D.).—We are not sure to what plant you refer by Coronilla Genista. In any case the plant should not be pruned now to any extent. Should the wall space permit, the better way would be to train the plant out fan shape against the wall, and thin out at

their bases those branches which cannot conveniently be laid in. Were you to adopt a general pruning now, the plant may be deterred from flowering till well into the summer of next year, even supposing the pruning did not militate against it passing the winter in safety. If you could send us a flowering spray or two, we might be able to name it for you and, with a fuller knowledge of the plant, assist you in more definite form.

FLOWERING AND FOLIAGE SHRUBS (T. H. H.).—The following are twelve of the most useful flowering shrubs: Ribes sanguineum atropurpureum, Forsythia suspensa, Spiræa arguta, Berberis stenophylla, Syringa persica, Diervilla Abel Carrière, Philadelphus Lemoinei erectus, P. coronarius, Cydonia Maulei superba, Viburnum tomentosum plicatum, Cytisus præcox and Escallonia langleyensis. Good coloured foliage shrubs are found in Cornus alba Spæthii, C. a. variegata, Sambucus racemosa plumosa aurea, Corylus maxima atropurpurea, Japanese Maples in variety, Acer Negundo variegata, A. N. californica aurea, Euonymus japonicus, golden and silver varieties; Hollies Golden Queen and Silver Queen, Prunus cerasifera atropurpurea, and gold and silver variegated Tree Ivies.

SHRUBS FOR A NEW GARDEN (Westmorland).—The following shrubs are likely to prove satisfactory if planted in your north border: Berberis stenophylla, evergreen, 5 feet to 8 feet, flowers yellow, April; Ribes sanguineum, 4 feet to 5 feet, red, April; Berberis Aquifolium, 2 feet to 3 feet, evergreen, yellow, March; Forsythia intermedia spectabilis, 4 feet, yellow, April; Cornus alba Spæthii, golden-variegated foliage, 4 feet; C. a. variegata, 4 feet, silver-variegated foliage; Tree Ivies in variety; and Hollies in variety. For the south border the following selection is suitable: Spiræa arguta, 4 feet to 5 feet, white, April; S. japonica Anthony Waterer, 2 feet, red, July and August; Diervilla Abel Carrière, 5 feet to 6 feet, rose, May; D. Eva Rathke, 3 feet to 4 feet, carmine, June and July; Cytisus præcox, 4 feet to 5 feet, cream, May; C. scoparius variety andreas, 4 feet to 5 feet, yellow and brown, May; Forsythia suspensa, 4 feet to 10 feet, yellow, April; Daphne Mezereum, 2 feet to 3 feet, red, February; Berberis Darwinii, 4 feet to 8 feet, evergreen, orange, April; Liliacs in variety; Philadelphus Lemoinei erectus, 3 feet, white, June; Viburnum lantana and V. tomentosum plicatum, white, 4 feet to 5 feet, June; also any of the subjects recommended for the other border. The following Roses will be likely to thrive with you: Hybrid Perpetuals—Ben Cant, Captain Hayward, Charles Lefebvre, Dupuy Jamain, Frau Karl Druschki, General Jacqueminot, Hugh Dickson, Mrs. John Laing, Sénateur Vaisse, Margaret Dickson and Ulrich Brunner. Hybrid Teas—Arthur R. Goodwin, Captain Christy, Caroline Testout, General Macarthur, His Majesty, J. B. Clark, John Ruskin, Kaiserin Augusta Victoria, La France, La Tosca, Lady Battersea, Liberty, Mme. A. Chateau, Mme. Jenny Gillemot, Mme. Pernet-Ducher, Mme. Ravary, Marquise Litta, Mrs. P. H. Coats, Queen of Spain, Richmond and White Killarney.

FRUIT GARDEN.

PEARS DOYENNE DU COMICE AND CALABASH, TO PLANT ALTERNATELY (Junius).—That will do very well. Doyenné du Comice is not the freest of setters, but it is self-fertilising, all the same. It will help it to set better if, when in bloom, you will inoculate its stigma (centre column of flower) with the pollen of some other sort in bloom at the same time.

STONES SPLITTING IN PEACHES (Sittingbourne).—Some varieties of Peaches and Nectarines, also Apricots, have split stones more than others. The varieties Peach Early Rivers and Nectarine Victoria are very liable to have split stones. Splitting of stones is always more prevalent when the roots of the trees are growing in a cold soil and when the soil is lacking in lime. The position should be a warm one, no check must be given to growth, and during the period when the stones are "hardening" in the fruits the soil must not be allowed to get very dry. If it does, and then gets saturated suddenly through heavy rains or watering by means of a watering-can, stone-splitting is worse than usual.

THE GREENHOUSE.

GLOXINIAS IN THE GREENHOUSE (Scotia).—These can be readily grown in a structure maintained at the temperature named; but in order to raise them from seed more heat is required. If you desire to grow Gloxinias, the better way will be to obtain one year old tubers; that is to say, the produce of seed sown early in 1913. During the dormant season these can be purchased at a comparatively cheap rate from dealers, and in this stage they can be sent by post at little cost. Good tubers should be about the size of a halfpenny to a penny. These should be potted, towards the end of February or early in March, in pots 3½ inches in diameter. A suitable compost may be made up of two parts loam to one of leaf-mould, with a sprinkling of sand. In potting, the tubers should be placed just below the surface of the soil, and watered lightly till the new growths make their appearance, when the soil must be kept moist. Keep in the warmest part of the greenhouse, and thus encourage growth. When the pots are well furnished with roots, the plants must be shifted into larger ones, 5 inches in diameter being a good size. The same compost may be used as in the first potting. During summer the plants will need to be shaded from the sunshine. As the plants develop, an occasional stimulant in the shape of liquid manure, or one of the many concentrated plant foods now available, will be beneficial.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Perpetual-Flowering Carnations.—The special society that exists for the promotion of the cultivation of these charming flowers, and known as the Perpetual Flowering Carnation Society, is a very live one. Its latest move is to offer affiliation to provincial horticultural societies, with a view to inducing them to include classes for this race of Carnations. This is a step in the right direction, and we wish it every success. The secretary, to whom all enquiries should be sent, is Mr. T. A. Weston, Floradale, Orpington, Kent.

The Forthcoming Chelsea Show.—We are pleased to learn that the spring show of the Royal Horticultural Society, to be held at the Royal Hospital Gardens, Chelsea, on May 19, 20 and 21, promises to be even better than the one held there last year. Two additional marquees, 300 feet long, are to be erected, and we hope that this means wider gangways, so that visitors can see the flowers with a greater degree of comfort. There were one or two other serious defects that ought also to receive the timely attention of the Council. In addition to these, the catering, suitable position for the band and facilities for Press photographers are items that someone with business acumen should be appointed to deal with.

Protecting Orchids at the Royal Horticultural Society's Hall.—All will agree that it is necessary to take every precaution against injury or theft, either of pollen or plants, of the valuable Orchids that are brought to the fortnightly meetings of the Royal Horticultural Society. We should have thought that the plants in question would have been sufficiently protected had someone been specially commissioned to guard them. To the great astonishment and disappointment of visitors, at the last meeting the special Orchids which had been judged for awards were placed behind an unsightly wire caging. It is to be hoped that the society will find a less offensive way of taking every reasonable care of choice Orchids, however rare and valuable they may be.

Natural Rock Gardens.—As a counter-scheme to the proposed "winter garden" at Edinburgh, a proposal has been put forward to convert the rocky pile that forms the foundation of Edinburgh Castle into a natural rock garden. Writing in *Country Life* last week, Miss Jekyll rightly points out that if this were done with proper regard to their wild and rugged character, beautiful effects could be obtained not only at Edinburgh, but at many other places where natural rocks exist. The sowing of seeds of such plants as Wallflowers, Red Valerian, the Harebell (*Campanula rotundifolia*), Pinks, Thrift and similar plants would be inexpensive, and the flowers would in no way detract from the natural effect of the rocks.

The Dutchman's Pipe (*Aristolochia Siphon*). In Southern Counties this makes an excellent

climber, either for the sunny side of a house or for clothing evergreen and other trees. Its popular name is taken from the resemblance of the flowers to the shape of the Dutchman's pipe. This plant is a native of North America, and so rapid is it in growth that it will readily ascend to a height of 25 feet or 30 feet.

The Japanese Roof Iris.—Writing from Japan in 1899, the late Mr. Peter Barr referred to *Iris tectorum* as growing freely on the thatched roofs of cottages in the country villages, and at the end of April and May producing masses of beautiful blue flowers, rising from rich green foliage. We should be glad to hear from readers if any attempts, successful or otherwise, have been made to grow this Iris under similar conditions in this country.

Violets in Pits or Frames.—These should be freely ventilated throughout the winter unless the weather is frosty. The plants may be grown in pits, from which the lights are removed whenever the weather is favourable. Water two or three times during the winter, when sufficient should be given to reach the extremities of the roots. Damping among Violets is the result of bad ventilation more frequently than from any other cause. Remove decaying foliage and stir the soil among the plants whenever it becomes necessary.

Sweet Corn as a Vegetable.—Those who wish to grow some of the better forms of Maize or Sweet Corn for the dining-table ought to sow the seeds during the next week or two, as it is essential to have strong plants for the open garden by the end of May. If sown singly in 3-inch pots in a warm house or frame, germination will not be very slow, and the seedlings should be potted on into larger pots as often as necessary, so that by the time all danger of frost is over, they will be sturdy plants nearly two feet in height and probably in pots 6 inches in diameter. Soil composed of loam two parts, decayed manure one part, and some coarse sand added to the whole answers well for potting. Several varieties suitable for this country are offered by the leading seedsmen.

A Beautiful Mezereon.—*Daphne Mezereum grandiflora* is one of a dozen or so shrubs which bloom during the darkest days of the year, and for that reason alone it is of considerable value. But its beauty is such that it would be awarded a conspicuous place in the garden even if it flowered during April and May, when the majority of flowering shrubs are at their best. It is a somewhat more vigorous plant than the common Mezereon, and its flowers are rather larger and deeper-coloured than those of the type. Unfortunately, it is not easily produced from seeds, and must be grafted upon roots of young plants of *D. Mezereum*. For this reason it is scarce and rather difficult to procure. It is sometimes called *autumnalis*, on account of some of the flowers opening during late autumn; but as a rule it is during late December and January that its flowers are seen to the greatest advantage.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The History of White Heather.—I should be greatly obliged if any reader could give me information as to when and how white Heather came to be regarded as the symbol of good fortune and luck. Is there any reference to it in this respect in any well-known book? Thanking you in anticipation,—R. O.

Primula pulverulenta Mrs. R. V. Berkeley.—Your contributor on page 22 of January 10 issue writes with regard to Primula Mrs. Berkeley that its flowers are of a soft rosy orange shade, with a deeply coloured eye. Apart from this, he says it comes true from seed. This is very interesting. When Messrs. Veitch and Sons of Chelsea first introduced the variety Mrs. R. V. Berkeley into commerce, I bought some plants. The firm came into possession of this Primula in rather an interesting manner. Among some

good deal of labour and oftentimes disappointment, as they are very subject to damping. Now that they may be relied upon to come true from seed, their popularity is increasing rapidly. The intermediate class is certainly the most useful for ordinary bedding purposes, although the tall varieties may be made use of in many ways. The dwarf or Tom Thumb section is not durable enough to be made use of in important schemes of bedding. A long, narrow border which was planted here last year contained both tall and intermediate sections, with their heights and colours judiciously mixed together. This proved to be most showy and effective, and called for general admiration all through the summer and autumn. It is often said that the Snapdragon will grow in any kind of soil, be it ever so poor; but I must warn those who wish to have a durable display of flowers till the end of the season that the plants must be grown well from beginning to end. For flowering this season the seed must be sown at once under glass. The varieties which find most

to cuttings removed from weakened plants. Heat and light for Perpetual-flowering Carnations must go hand-in-hand. If you have a light, airy greenhouse, you can have more heat than if you have an old-fashioned one with heavy rafters or one shaded in any way. The ideal Carnation house is one running from east to west and facing south, with an abundance of ventilation. Our Carnation houses cover a quarter of an acre each. In such a house the light and buoyancy of the atmosphere can be imagined, yet 50° at night is the average temperature. In a less favourably situated house 45° at night would be adequate to promote strong, natural growth. Many amateurs obtain really wonderful results from Carnations grown in cold greenhouses. The reason for this undoubtedly is that it is better to err on the cold rather than on the hot side in growing Perpetual-flowering Carnations.—MONTAGU C. ALLWOOD, *Hayward's Heath*.

A Beautiful Hardy Heath.—*Erica lusitanica* (codonodes) is now fully in flower in the open, and it is surprising to find how little one sees of it or how few garden-lovers even know there is such a glorious winter-flowering hardy plant. Having been cordially invited by Mr. Cox, the genial gardener to Lord Eustace Cecil, to view the grounds at Lytchett Heath, on a cold day (December 29) I embraced the opportunity of calling when staying in the district, and I can only say that a greater winter treat in the garden was never before presented to me. The great aim in this fine establishment is to allow Nature to perfect herself in the arrangement of all kinds of subjects; but it is to *Erica lusitanica* I should particularly like to draw your attention. The soil is of a good brown loam, somewhat on the sandy side, but not the poor, shallow moor ground that one would expect to find on the hillside, where common moor soil seems everywhere else but here. The plants, perhaps, cover altogether two and a-half to three acres, though spread about they really look to cover more. About thirty-five years ago a dozen or so plants were put in and allowed

ERICA LUSITANICA, NOW IN FLOWER IN THE HEATH GARDEN AT KEW.

seedlings raised from seed, sent from China by their collector, this white variety of pulverulenta first made its appearance. It had a cream white flower, with rich orange eye and mealy stem. The ones sent me corresponded in all details to their description. I seem to remember that some of the later flowers, when fully matured, showed a faint orange pink tinge. Further, my plants, so far, have failed to form seed, and on enquiry I find that those of Messrs. Veitch have behaved in the same way. Now, I should like to know if the variety Mrs. Berkeley spoken of by your contributor is the Mrs. R. V. Berkeley of Messrs. Veitch and Sons, and, if not, where his stock originated and where seeds can be obtained.—JOHN MACWATT, *Morelands, Duns*.

Antirrhinums as Bedding Plants.—It is doubtful if there is another race of plants more useful for bedding purposes than the Antirrhinum. A year or two back it was necessary to propagate the stock from cuttings in the autumn to ensure the plants coming true. This, of course, meant a

favour are Delicate Pink, Coral Red, Deep Crimson, Apricot, Orange King, Fire King, Carmine Pink, Yellow, and White.—E. HARRISS, *Lockinge Gardens, Wantage*.

Heat and Light for Perpetual-Flowering Carnations.—If I were asked what were the two greatest enemies of the Perpetual-flowering Carnation, I should certainly say improper manuring and excess of artificial heat. Few gardeners realise that it is impossible to cheat Nature. At least, if you do cheat her by forcing your plants one season, she retaliates the next. Hence if you give Perpetual-flowering Carnations an excess of artificial heat during the winter months, you force their growth and thus weaken it; and when once a Perpetual-flowering Carnation has been weakened through improper cultivation it is practically spoilt. Being perpetually growing, it has no dormant or resting period, like other plants, to recuperate its strength and become strong. This must be obvious to every thoughtful cultivator, and all too many failures can be traced

to do as they liked. As year by year went on, the annual seeding of the plant brought progeny after progeny, till there is now a perfect plantation of it. Nothing can withstand the onward march of this plant; Brambles, Gorse, and common Heather all have to give way to the advance of this Tree Heath, which appropriates the entire surface of the ground as time goes on. Plants are in flower in all sizes from 9 inches high to 14 feet, but the bulk of this forest of Tree Heath range in height from 7 feet to 10 feet. Standing up on the outside terrace walk and looking down at it from various standpoints, it looked like a whole hillside of deep green feathery Tamarisk, each top thickly terminating in a pyramidal spike of white Heather flowers, sometimes faintly tinted with pink, but with scarcely any variation. The soil has never been broken up, and between the plants, before they get matted together, the surface is covered with short moss and weakly grass. I am told by the head-gardener that it is rabbit-proof.—MAURICE PRICHARD, *Christchurch, Hants*.

The Christmas Bush.—Replying to an enquiry in your issue of the 3rd inst., you express your inability to recognise the Christmas Bush. This is *Metrosideros tomentosa*, or Ironwood Tree, or Downy Rata. Its Maori name is Pohutukawa, and in New Zealand it is often known as the Christmas Tree.—A. L. FORD.

Mistletoe Growing on Pear Trees.—*Re* the interesting article on "Some Peculiarities of Mistletoe" by "C. Q." in THE GARDEN for December 27, 1913, it looks as though your correspondent has inadvertently overstepped the mark of strict veracity by the emphatic statement that Mistletoe is never found growing on the Pear tree. If it is a fact that the occurrence has not yet been recorded, it may be an item of some interest to the numerous readers of THE GARDEN if you will kindly permit me to state that there is a Pear tree, some 40 feet high, growing in the gardens here which carries at the present time four healthy specimens of the parasite. They are dispersed at various heights in the tree on different branches. The largest plant is about two feet in diameter, and all are looking normally healthy. So also are all the parts of the host tree on which they are growing. The Pear tree is the variety Thompson's, and the parasitic plants are all naturally sown. Other instances of trees that I think are of rare occurrence as playing the successful part of host to this parasite are the Medlar and the Persian Plum. Both of these trees I have seen with large and healthy specimens of Mistletoe established thereon.—W. J. RENDALL, *Fern Lodge Gardens, Malvern Link.*

January Roses.—As instancing the abnormal season, I cut on January 11, from the open ground, sufficient Roses of the following varieties to make up two large vases for the table, mostly of very good colour and quality: Corallina, Lady Hillingdon, Safrano, Climbing Papa Gontier, Billiard et Barré, General Gallieni, Nita Weldon, Mme. Bruant, Mrs. A. Coxhead, Irish Elegance, General Macarthur, Grüss an Teplitz, Noella Nabonnand, Mme. A. Chatenay, Mme. A. Carrière, Comtesse du Cayla, Leonie Lamesch, Leontine Gervaise and Green Mantle. It will be noticed that most of these are either pure Teas or carry Tea blood, but the Chinas, Polyanthas and wichuraianas are represented, and even the Penzance Briars. Grown on high ground exposed to all weathers, these Roses lay under an inch of snow on December 28, and on New Year's Day there was skating in the neighbourhood. Until Christmas, Frau Karl Druschki, Caroline Testout and several other exhibition Hybrid Perpetual and Hybrid Tea plants gave blooms quite up to National Rose Society's Autumn Show form, but they are now proceeding comfortably with their belated winter sleep, whereas many of the Teas remain quite active. It is to be feared the result of such dissipation will show itself later. Since May 15, when Rosa sinica Anemone opened the ball, my table has not been without a vase of Roses cut from the open ground. What other flower can show such a record?—F. A. G., *Worcester.*

FORTHCOMING EVENTS.

January 27.—Royal Horticultural Society's Exhibition of Flowers, Plants, &c., 1—6. Lecture at 3 by Professor W. Somerville on "Some Aspects of American Forestry."

January 29.—Manchester and North of England Orchid Society's Meeting.

January 30.—Beckenham Horticultural Society's Meeting.

THE TREATMENT OF FROZEN PLANTS.

IN the extremely variable climate that is characteristic of the British Isles during the winter months it is not surprising to find that many amateurs, and some professional gardeners, suffer severe losses by frost. It is one of the curious and none the less vexatious ironies of gardening that the heating apparatus of greenhouses or frames, if it ever does fail at all, will do so just when the country is in the grip of frost, and the gardener under those circumstances finds, when he pays his morning visit, that many, if not all, of the contents of the houses and frames are frozen. In some instances he is, perhaps, to blame; but even in the best regulated gardens accidents of this kind will occur, and it is as well to know the best course to adopt under these or similar circumstances. Believing as we do that prevention is better than cure, it is advisable to remember that plants which are in a comparatively dry state suffer far less from frost than those of a similar kind whose tissues are turgid with moisture; hence the wise gardener will see to it that they have the lowest possible quantity of water during frosty weather, without, of course, allowing them to suffer in that direction. The reason is this: As every student of plant physiology is aware, a plant is made up of innumerable thin-walled cells, and that these are more or less filled with moisture. When this becomes frozen, it, under a natural law, expands and the delicate walls of the plant cells are ruptured. It is thus obvious that the more highly charged these cells are with moisture, the greater will be the damage to the cell walls; hence the advice to be sparing with water during frost.

But Nature, in her wisdom, has to some extent provided against damage by this rupture of the cell walls, and it is quite possible for the tissues to right themselves, providing the conditions for doing so are favourable; hence the gardener who is conversant with these conditions is well on the way to saving, it may be, a valuable lot of plants, some of which it might be exceedingly difficult, if not impossible, to replace. Briefly, the conditions favourable for recovery are very slow thawing. It is sudden thawing, brought about, it may be, by a burst of sunshine or correction of the heating apparatus, that is so disastrous to frozen plants. Knowing the cause of damage and the conditions best suited for minimising it, the cultivator will not be slow to bring about such conditions. First of all, the houses or frames should be shaded if there is danger of sunshine; then the whole of the frozen plants and woodwork be syringed with water that is as near freezing point as possible, keeping this up until satisfied that frost has departed. This will be an exceedingly cold and unpleasant task, but one that may mean the difference between saving and losing most of the plants. It will be necessary to keep them as cool as possible, without letting frost actually reach them, for a few days afterwards. This treatment applies to all forms of plant-life, whether hard-wooded, like the Rhododendrons and Camellias, or soft-wooded, like the Chrysanthemums or Primulas. The chief points to observe are to keep the water supply at the roots as low as possible, and, in the case of the plants being frozen to shade them for some hours, and to syringe them overhead with icy cold water. H.

DAFFODIL NOTES.

The Royal Horticultural Society's Daffodil Year Book.—I think it will be good, if to some rather old, news to learn that the 1913 edition has been sold out a good many weeks since, and that its reception has been such by Daffodil people that the President and Council have already determined upon a second one this year. They have honoured me by again appointing me editor or collector, and I have begun my work by trying to secure much more information about Australian and New Zealand doings than I was able to incorporate in No. 1. I believe the Daffodil to be a world's flower, and that there is a long future before it. For instance, I have recently learnt that they can grow their own bulbs in Sweden; and although I have heard two contradictory accounts of how they do for early pot work from a Swedish friend, I have had a present of some which I am growing in my own garden at Whitewell. To go back to the Year Book. It has occurred to me that it would be very interesting to have a chapter of *short notes* from as many observers as possible of anything that specially strikes them about the flowers or shows, or other matters connected with the Daffodil. Would anyone, *when* he has anything to record or say, *at once* jot it down and send it to Whitewell Rectory, Whitchurch, Salop, "lest he forgets."

Early Flowers.—In this abnormal season I expect many people will have instances of abnormal times of blooming to record. My abnormalities have been a seedling of *Narcissus Bulbocodium citrinum* in full flower in November, and a seedling Poetaz (*Chaucer* × *Soleil d'Or*) out on January 6. I have a nice little batch of this cross, and it will be interesting to see if the majority inherit the early flowering propensities of their parents.

Royal Horticultural Society's Awards to Daffodils.—Readers may remember that the new scheme of awards was published some time back in THE GARDEN. I have heard from several prominent members of the *Narcissus* committee, and they all express their approval and say that it is just what is wanted. The Midland Daffodil Society formally adopted it at its special general meeting last December. I take this opportunity of urging all societies, both at home and abroad, to "go and do likewise." If anything should tend to popularise the Daffodil, this scheme should, if enough use is made of it by Daffodil people generally and if the *Narcissus* committee administers it in a broad-minded and thoughtful way. The modern *Narcissus* is a ubiquitous race in the aggregate, but not so all its individual members. They develop preferences early in life. Like a wise parent who wishes his children to adopt the several callings which are most suitable for them, and who gives each the best training and "send off" he can with this object in view, the Royal Horticultural Society in these awards gives each variety its chance by pointing out the special purpose or purposes for which it is most fitted. There are a large number of splendid garden plants which should now have this distinction appended to them. I sincerely hope all these will be brought before the committee, and that each one will receive its due. I believe the Daffodil-buying public want to have a list of good, reliable garden plants, and not just the names of one or two of superexcellence. For these the first-class certificate might, and would, be reserved. I hope readers will favour me with their views. JOSEPH JACON.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

(Continued from page 36.)

Hardy versus Bedding Plants.—Long was the opinion cherished that hardy flower gardening as compared with the exclusive use of "bedding" plants was to lessen labour, worry and expense to a considerable extent, and there are probably some who to this day are not yet satisfied that such is not the case. Were the custom of planting borders and beds thinly with a collection of hardy plants, and leaving them for years practically to themselves, to be substituted for tender bedding plants, that might be true; but to secure an equally brilliant display of bloom, with the plants and their environment kept equally well, the hardy flower man has nothing in his favour in the above respects. If we take the round of the year and jot down the essentials that cannot be omitted without to some extent depreciating the beauty of floral schemes, and thereby lessening interest in the garden and losing the fruits of much thought and labour, it will be obvious that hardy flower gardening is no mere work that can be taken up at odd minutes, or left altogether should no odd minutes occur in the gardener's experience.

A—Plant prepared by root pruning for transplantation. B—Ball of same plant when lifted. Dotted line shows depth to replant.

Beginning in October or November, the final clearance of worked-out material must be undertaken, whether or no rearrangement or replanting is to be done. Anyhow, as previously noted, sections of the border must be recultivated and replanted, and the rest of it manured and dug, or, if digging is repugnant, then surface-dressed in a thorough manner. The less hardy material, *e.g.*, *Lobelias* of the cardinalis section and *Montbretias*, as a rule, must be safely stored till spring, when, as soon as the surface soil is dry enough, clods must be broken and a smooth surface produced. The planting of blanks left for the purpose of being filled with *Sweet Williams*, *Hollyhocks*, *Lychnis coronaria* varieties, *Carnations*, *Montbretias*, *Hyacinthus candicans* and *Tiger Lilies* must be proceeded with in detail. Early planting, as a rule, always gives the best results, and especially when the summer is dry and abnormally warm. Following these come *Gladioli* and, a little later, *Sweet Peas*; perennials raised under glass—*Delphiniums*, *Celsias*, *Lupinus polyphyllus* varieties and others, *Antirrhinums*, *Stocks* and *Larkspurs*, similarly produced, the time and labour incident to the production of these being also taken into account. Meanwhile, hoeing, if a hoe can be insinuated between the close-set plants, hand-weeding, removal of *Snowdrop* and *Winter Aconite* foliage as it decays, and, later, of that of other bulbous plants, must be attended to, and

quantities of *Chrysanthemums*, *Marigolds*, *Asters*, &c., for transplanting in August and September be put into a piece of reserve ground. Plants not usually found in herbaceous borders, such as *Francoa ramosa* and *Agapanthus umbellatus*, give character, and room for them may be found in prominent positions during the early summer.

Staking and Tying.—In May or early in June the question of supporting the plants comes up for consideration, and here much misspent time and labour occurs, a very large number of plants which need not be supported being usually held up by means of stakes, as well as others which, being strong enough to withstand unaided all kinds of weather, need no support whatever. Of the latter, mention may be made of *Senecio tanguticus*, *S. Clivorum*, *Liliums*, *Aconites*, *Chrysanthemum uliginosum*, *C. maximum* varieties (young plants), dwarf and medium tall *Phloxes*, many of the tall *Composites* and dwarf *Starworts*. There is another class which requires merely a band of string loosely arranged around the stems, and includes many of the *Starworts*, such as *Aster Linosyris*, *A. asteroides*, *A. Nancy*, *A. pulchellus pulcherrimus* and *A. Tradescanti*, the bands being removed when the plants are coming into flower in order that they spread out naturally. *Stenactis speciosa*, *Solidago* and *Eupatorium ageratoides* are others. Then, of those plants which must

have the support, of a stake or stakes, there is a section which needs, for the height of the plants, comparatively short ones; only, and this applies to all the means used for supporting plants, they must be staked at an early stage or before they have swayed in the least from the upright—*Larkspurs*, tall *Antirrhinums*, *Hollyhocks*, *Dahlias*, *Gladioli*, tall *Asters*, such as *John Wood*, the *Novæ-*

Angliæ section, *Climax*, very tall *Phloxes*, *Lupinus* and many more. The number of those requiring stakes almost their own height are very few, one of the best known being the *Carnation*, which is apt to be broken by tits unless protected in this way. There is a small section which may, when the plants are large, require more than one stake, examples of which are *Pyrethrums*, *Lupinus polyphyllus*, *Echinops Ritro*, *Galega officinalis alba*, *Geranium pratensis flore pleno*, *Pæonies* and *Achillea Millefolium rubra*. From three to six stakes for these are inserted at equal distances round the plants, and stout string attached to each keeps the plants from sagging, while at the same time the supports are not visible—an essential in good staking. There are other methods of supporting plants by means of short, stout *Spruce* branches (dead, of course), and an ingenious method, noted in a recent book, by means of wide-meshed wire-netting. For some things I occasionally stoop to pegging. To dwarfen *Dahlias* it is a capital expedient, and *Gypsophila paniculata*, an ugly thing when staked, if pegged down round the sides, is quite charming.

Another constant call for labour throughout the summer is that of keeping plants within due bounds. Neither in height nor laterally should any plant be allowed to transgress in these particulars. A plant or plants will often be found overtopping others behind them, and the

plan to pursue with these is to pinch or cut them back to a proper height. *Composites* of all kinds submit to this. Lateral growths should be carefully restricted without it being possible to see, unless searched for, that it has been done. The removal of decaying flowers and those which if left would produce seed is another item which claims unremitting attention. If plants which are properly attended to in this respect do not continue to produce flowers, as many do, most will at least retain their foliage fresh and green; but there will always be a few which must be cut down, and to fill the blanks, and all other blanks, one must fall back on the reserves planted in the early summer to meet surprises of this kind. I am aware that many gardeners have a dislike to undertake the filling of blanks, esteeming the extra labour uncalled for; but it takes merely a few hours now and again, and the time need not be taken while other more important work is waiting. The operations are very simple—merely to see that the holes for the plants are deep enough to let the ball be covered 1 inch or 2 inches deeper than it was previous to transportation, not to attempt to secure a larger mass of earth with the roots than will remain attached to them, to plant firmly, to stake if required at once, and to saturate with water very thoroughly the ball and the new surroundings, choosing dull weather or late in the afternoon for the work.

Watering.—The application of water in periods of drought and how best to manage it requires a few words. And it is to be remarked that it requires less water to moisten firm than loose soil, which also retains moisture longer. Pure water, again, is far less valuable than water strengthened with a fertiliser, the cheapest being superphosphate of lime, 1 oz. to every three or four gallons of liquid. Sulphate of ammonia may be substituted on occasion if growth hangs unduly, but I find the first named usually sufficient. Theoretically, we are told that manure-water should not be used on dry soil till it has been moistened with pure water. Practically, that is a mistake, and I never apply pure water to established plants under any conditions. Gardeners are averse to apply water even where the supply is unlimited; but in a season like the past it is impossible to have plants in satisfactory condition unless quite a number are watered at regular intervals. Close planting, though it would appear to be a means of exhausting the supply of moisture more rapidly, really conserves it. Even in the last season a large number of plants came through the drought without needing water. *Rudbeckias* are among the first to suffer. *Phloxes*, *Pentstemons*, *Gladioli* and *Stocks* are other common plants which are not drought-proof, and, of course, many, or most, others are all the better for regular applications during long periods of drought.

Prestonkirk, N.B.

R. P. BROTHERSTON.

(To be continued.)

SHRUBS IN FLOWER BORDERS.

WHERE ornamental shrubs are growing in the herbaceous or mixed border, it will be necessary to check their roots each winter otherwise they will rob the soil of much nourishment that ought to be available for the more legitimate occupants. The thrusting of a sharp spade well down into the soil all round the shrub, and nearly as far away from the main stem as the branches extend, is a rough but simple and effective method of attaining this end.

B. B.

WINTER - FLOWERING
SHRUBS.

THE WITCH HAZELS (HAMAMELIS).

THE Hamamelis are in the front rank of winter-flowering shrubs, the several representatives

THE NORTH AMERICAN WITCH HAZEL, HAMAMELIS VIRGINICA.
THIS USUALLY FLOWERS FROM OCTOBER TO DECEMBER.

of the genus blooming over a period of some six months, from October to March. Six species and one variety are in cultivation, all being deciduous shrubs or small trees. The Witch Hazels thrive best in a well-drained, rather light loam, in which it is worth while mixing some leaf-mould and peat. They are propagated from seeds, or by grafting, under glass in early spring, using the American Witch Hazel (*H. virginica*) as a stock. It is worth while taking a little pains to select good positions for the Hamamelis, for two reasons. In the first place, flowering in winter, severe frosts damage the open blossoms. Though the buds are uninjured and several degrees of frost do not appear to damage the open blooms, it is very desirable to plant the Witch Hazels in positions sheltered from the north and east, and even the south-east, to avoid the early morning sun reaching the flowers while they are frozen. A second desirable point is to have evergreens as a background, it may be a few yards away, to show up the flowers, the Hamamelis blooms appearing in advance of the leaves. A group of Witch Hazels in full flower in January or February, with the sun shining on them against a dark background of Yew or Holly, presents a charming

picture. Taken in the order in which they bloom, the first species to be briefly described is

H. virginica, the American Witch Hazel. The flowering season is from October to December, and although the individual flowers are not showy, during a fine late autumn and early winter large bushes laden with the starry brownish yellow blooms are very pretty and interesting. A native of the Eastern United States, *H. virginica* was the first species of Hamamelis introduced to British gardens, the year 1736 being given as the probable date.

H. mollis, the Chinese Witch Hazel, is the most beautiful and attractive member of the family. Flowering during December and January, words cannot adequately describe, or an illustration do justice to, a bush of this Witch Hazel. The narrow, rich yellow petals, about an inch long, are prettily curved at the tips. The flowers are deliciously, even powerfully fragrant. When we have larger bushes and more of them, the Chinese Witch Hazel will be in demand for cutting. Sprays last fully a fortnight in water when cut, the fragrance being very pleasing in a room. *H. mollis* is distinct from other species in summer, having much larger, broadly oval leaves, 6 inches long and

3 inches to 4 inches broad, and very hairy. It is readily propagated by grafting on stocks of *H. virginica*, young plants commencing to flower the second year after grafting when about 1 foot high. We are indebted to Charles Maries for this beautiful Witch Hazel, which he introduced from China when collecting on behalf of Messrs. J. Veitch and Sons from 1877 to 1879.

H. arborea.—A native of Japan, this species forms an upright-growing bush or small pyramid-shaped tree. The first flowers usually open during January. The narrow, golden yellow petals are curiously twisted, giving the flowers a starry appearance. It is free-flowering, and the sprays are useful for cutting. Introduced in 1862, the Japanese call the tree the

Mansak. With them it is a tree 20 feet or more in height.

H. japonica.—Another Japanese Witch Hazel, this species never attains anything approaching the height of the last named, being quite a bush up to 6 feet or rather more in height. The flowers are, if anything, a little paler than *H. arborea*, and as a rule they are rather later in opening. A variety of this species, *zuccariniana*, has very distinct and attractive citron yellow flowers. Next to *H. mollis* I should put it as the most showy and desirable to cultivate.

H. vernalis.—This species hails from America, and is a recent introduction to this country. It has been described as a spring-flowering *H. virginica*. Plants of this have flowered at Kew, but, as they are small, it is early yet to form an opinion of their value.

Another closely allied tree at present in flower is *Parrotia persica*, a native of Persia. Other members of the Natural Order Hamamelidaceæ grown in our gardens include several species of *Corylopsis*, *Fothergilla major* and the *Liquidambar*.
A. O.

SHRUBS FOR COLOUR
EFFECTS.

SOME shrubs are seen at their best when grown as isolated specimens in open positions; others can only be used with telling effect when planted together in groups. In the following notes I

THE NEW CHINESE WITCH HAZEL, HAMAMELIS MOLLIS,
WHICH FLOWERS IN JANUARY. NOTE THE SIZE OF THE
FLOWERS COMPARED WITH THOSE OF THE OTHER SPECIES.

intend to give six of the best shrubs for massing in large, bold beds. Foremost among such shrubs are the

Azaleas, or Swamp Honeysuckles, which produce an abundance of their fragrant blooms in warm tones of orange, pink, and red during May and in the early days of June. Although usually referred to as North American, the varieties of the Swamp Honeysuckle are mainly of hybrid origin, being derived from *A. nudiflora*, *A. viscosa* and other species. These shrubs require peaty soil and sheltered positions. The elements they resent most are lime and cold winds; but, given suitable conditions, there are no shrubs to excel them for colour schemes in beds or borders.

Viburnum plicatum, or Japanese Guelder Rose.—In the writer's opinion this is worthy of second place by virtue of the beautiful trusses of white flowers, so profusely borne as to almost hide the dark verdure of the leaves which form the background. It is one of the easiest shrubs to cultivate, for it is perfectly hardy and yields excellent results in a moderate soil. It is sometimes known as *Viburnum tomentosum plicatum*.

the surrounding landscape. It is as hardy as the Gorse, and will thrive in almost any soil.

Hydrangea paniculata grandiflora.—The list is concluded with one of the most delightful of all the late summer-flowering shrubs. This *Hydrangea* is noted for its massive plumes, often more than a foot in length, of pure white blooms. It needs a good soil and a heavy mulching in winter, and requires to be pruned hard at this season to keep the plants within bounds, for if left to grow unchecked it might easily attain a height of 20 feet or so.

C. Q.

JAPANESE LILIES FOR THE GREENHOUSE.

AS the finest bulbs of the different Lilies from Japan are now reaching this country, the present is a good time to take them in hand where they are required for potting up for the decoration of the greenhouse or conservatory. If delayed later, the bulbs are apt to deteriorate when removed from their coating of clay in which

markings thereof, as well as in the time of flowering and other particulars. Of the well-marked varieties that can be obtained true to name are *platyphyllum*, or *macranthum* as it is sometimes called. This has tall yet stout stems, clothed with very broad leaves, while the saucer-shaped blossoms are unusually large and of a thick, wax-like texture.

L. platyphyllum virginale is a counterpart of the preceding, except that the flowers have few, if any, spots, the only colouring being a yellow band down the centre of each petal. In *rubro-vittatum* the flowers are quite distinct from any other, the golden stripe down the centre of each segment being replaced by a bright crimson one. When first expanded this is most striking, but the crimson becomes somewhat dull a good while before the petals drop. This variety is less vigorous than either of the preceding, a remark which applies also to *Wittei* or *virginale*, an unspotted flower with a central band of yellow. The bulbs sent here from Japan of the two varieties *rubro-vittatum* and *Wittei* are smaller than those of the other forms; but, as far as my experience extends, they can be depended upon to flower well, and are less liable to die off in that unaccountable manner characteristic of *L. auratum* itself. An exceedingly valuable Lily for pot culture, as well as for the open ground, is

L. speciosum. The flowers have not the heavy perfume of *L. auratum*, while, when growing, the foliage is much less liable to be attacked by aphides than *L. longiflorum*. There is a considerable amount of variation in the different varieties of *L. speciosum* (*lancifolium*), the flowers ranging in colour from white to rich carmine or crimson. Of white varieties, the most generally met with is *Krätzeri*, of sturdy growth, with bright green leaves and stems. The flowers, which reflex very regularly, are of the purest white, with a greenish stripe down the centre of each petal. To the ground colour of the flower the dark chocolate anthers afford a direct contrast. In this variety the bulbs are of a distinct yellow tint. Much in the same way as the preceding, but with bright yellow anthers, is *album novum*, a very fine flower. It is a good deal

scarcer than *Krätzeri*. The coloured varieties that we receive from Japan differ considerably from each other, in some the flowers being of varying shades of rose, but usually of a deep tint. A well-established and popular variety is *Melpomene*, whose large blooms are of a rich carmine-crimson margined with white. The bulbs of this variety are very liable to break up into two or three or even more crowns, so that they are somewhat irregular in shape, and will push up several stems. The variety *Melpomene* varies somewhat in depth of colouring and other particulars. A superior form, known as *magnificum*, has come prominently forward within the last few years.

There are several other Japanese Lilies that may be grown in pots, but not many of them are so treated other than those named above. The magnificent bulbs of that variety of the Tiger Lily known as *Fortunei*, which we receive from Japan, grand though they are in the open border, do not

A LARGE LAWN BED PLANTED WITH ESCALLONIA PHILIPPIANA, A WHITE-FLOWERED HARDY SHRUB.

Viburnum Opulus sterile (Snowball Tree).—This is a variety of our native bush, the Guelder Rose. The variety sterile differs from the type, in that its white flower-heads are round and much larger. The individual flowers, although bright and showy, are in reality barren or sterile, and in consequence are devoid of berries. Like the foregoing, it is quite hardy and not in the least fastidious as to soil.

Escallonia philippiana.—It is hard to understand why this very graceful subject is not more often planted. It is one of the hardiest of all the species, and is certainly hardier than *E. macrantha*, which, as a rule, needs the protection of a wall. It produces small white flowers. It is neat, but extremely graceful, as may be judged from the illustration on this page.

Cytisus scoparius sulphureus, or the Moonlight Broom.—The sulphur yellow flowers of this Broom are produced in such profusion during May and June that they appear to illuminate

they are sent to this country, as exposed to air they soon shrivel.

Lilium longiflorum, which is so extensively used for pot culture, has been here for some time, as it ripens earlier than the others. Still, the later consignments contain very good bulbs, which can be thoroughly depended upon to yield perfectly satisfactory results. We get several forms of this Lily from Japan, chief among them being the large, bold-growing *giganteum*, which is so much appreciated by those who grow them for commercial purposes; *formosum*, a fine, early-flowering variety; *Takesima*, remarkable for its brown stems; and *Wilsonii*, a very large flower, while the habit of the plant is particularly sturdy. Next may be mentioned

L. auratum, a really magnificent Lily, variable in character and erratic in behaviour. Even among what may be regarded as the typical kind a wide range is to be found, as different individuals vary in stature, size of flower and the

do as well in pots as the variety splendens, which is grown by the Dutch.

Cultural Hints.—The Lilies enumerated here may be potted singly, while large masses or clumps may be made up by putting two or three or more together in a pot, or even in a tub. The soil should be of a fairly lasting nature, such as two-thirds loam to one-third peat, with a liberal sprinkling of sand. In potting, it is a good plan to place a little clean sand around the base of the bulb. After potting, a good place for them is a cold frame, where they are just protected from frost. Under these conditions they will root slowly but surely. Not much water will be required till the shoots make their appearance above the ground. It should be borne in mind that the foregoing are all stem-rooting Lilies; that is to say, they push out a quantity of roots from the base of the flower-stem. On this account space should, when potting, be left for a top-dressing of good soil when these roots make their appearance. These remarks apply to bulbs newly imported from Japan, and not to retarded ones, which need different treatment. H. P.

THE FRINGED HOUSELEEK.

(SEMPERVIVUM FIMBRIATUM.)

This beautiful Sempervivum will grow quite as happily over the surface of a rock as the Sengreen or common Houseleek will over the roof of an old tiled building. The very name Sempervivum is derived from *Semper vivo*, to live for ever, in allusion to the well-known tenacity of the species. Sempervivum fimbriatum is specially to be commended for the rock garden. It is a native of the Alps of Dauphiné, and is uncommonly attractive when in flower, usually in July or August. The inflorescences are from 6 inches to 10 inches above the rosette of foliage, and the individual flowers are bright rosy red in colour. The flowers, which are about an inch in diameter, are delicately fringed, and borne profusely in branching panicles. The leaves are usually green, with the outer ones turning red, but position, and possibly the rooting medium, affect the colouring of the rosettes considerably. It is very easy to establish between the chinks of rocks or on old ruins, where just a little soil may be placed at planting-time. Like most of its family, it may be increased by offsets, which are abundantly produced.

A BEAUTIFUL EARLY CROCUS.

CROCUS IMPERATII, a delightful Italian species, is one of the first to show colour. The interior of the sweetly scented flowers is lilac purple, while the outside of each segment has three dark purple lines. The pretty effect produced at this season when grown in quantity is not readily surpassed. It is a good Crocus for planting on lawns, but is seen to even better advantage on a sheltered slope of the rock garden. There are several varieties of C. Imperatii, including a white form as well as a double-flowered one.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER CLIMBING ROSES.

(Continued from page 35.)

Miss Hellyett (Fauque et Fils, 1910).—This is one of the largest-flowered of all the wichuraianas. The blooms are produced generally on single foot-stalks, and in the bud are very beautiful, not unlike Lady Waterlow. The open flower, however, resembles Mme. Antoine Mari. A very beautiful Rose and a very rampant grower; its only fault is that it is not particularly free-flowering with me. This may be due to its position in my garden, as it is facing almost due north.

THE FRINGED HOUSELEEK GROWING OVER A BOULDER IN THE ROCK GARDEN.

Mrs. M. H. Walsh (M. H. Walsh, 1913).—My plant of this has not flowered, but it was strongly recommended to me as by far the best white wichuraiana, and with our White Dorothy Perkins insisting on throwing pink flowers with the white, it should find a place. It flowers in clusters; the flowers are double and rather larger than White Dorothy.

Rowena (W. Paul and Son, 1912).—This is quite good. The colour is distinct and a pretty shade of carmine pink. The flowers are produced in fairly long clusters, though they are not too thickly placed on the panicle, which is, to my way of thinking, a distinct advantage.

Shower of Gold (Paul and Son, 1910).—This is one of the best of the yellows. The flowers are produced singly all over the plant. Here again the

foliage is very fine; not quite up to Klondyke, perhaps, but similar.

Source d'Or (Turbat and Co., 1913).—This is strongly recommended to me from the Continent as a large-flowered yellow, with very vigorous growth for a plant of that colour. The plant I have promises well, but I have not flowered it yet. To pass to other sections:

Adrian Riverschon (Lambert, 1910).—This is a single Rose, a rather thin-looking Leuchtstern, with considerably more white in the centre of the flower; a Polyantha.

Ariel (Paul and Son, 1910).—Another Polyantha, but sometimes called a hybrid wichuraiana. It is a pretty, single-flowered, bright pink, with coppery-coloured buds; a good grower; best described, perhaps, as a single Tea Rambler.

Florence H. Veitch (W. Paul and Son, 1911).—A fine, bright, almost scarlet, crimson flower, but only a semi-climber; best grown as an isolated bush, or would make a good dwarf pillar Rose. Sweet-smelling; flowers not very full, but lasting well.

Climbing Lady Ashtown (Bradley, 1910).—This has been good with me, and but for its liking for mildew could be highly recommended. It is quite free-flowering and continuous, but the first flowers are the best, both as to size and colour. The difficulty is to prevent the plant getting leggy at the base. For this reason it should be on a pergola, and then its legs can be trousered with another plant.

Climbing Richmond (Alex. Dickson and Son, Limited, 1912).—This has been excellent with me in 1913. Cut down to the ground in 1912, it spent the summer making wood which has bloomed freely, and I have now some nice shoots for this year on an arch; but it is not vigorous nor spreading enough to cover the same, and must have company. It is much to be preferred to Climbing Liberty, which has refused to climb here, although I have seen some very fine plants of it under glass.

Climbing Mme. Melanie Soupert (Burrell and Co.).—All lovers of this Rose will welcome its climbing form, which will be distributed this summer by Messrs. Burrell. I have a very fine plant that shows that there is no doubt about its climbing; but I have not yet flowered it, and am looking forward with a considerable amount of

pleasurable anticipation to doing so. It is a great addition to these climbing sports.

Climbing Souvenir de Pierre Notting (Frank Cant and Co., 1912).—I have already mentioned this in THE GARDEN. It is quite one of the best of the rather long list, and is still giving me flowers from the laterals of last year's growth. Strongly recommended, as it is a very vigorous grower, much more so than most of these climbing sports.

Moonlight (Rev. J. H. Pemberton, 1913).—As a bush or dwarf pillar, this is a very great addition to the perpetual semi-climbers. The flowers are produced from June to November in clusters, after the style of Trier, without any of the pink that shows in the buds of that variety. Its colour is lemon white and the flowers are semi-double.

Danae (Rev. J. H. Pemberton, 1913).—This is of similar growth and habit, but the flowers are much fuller and have more colour in them. The buds are deep yellow and the open flowers pale yellow, of the size of a florin. I think both these Roses of Mr. Pemberton's raising can be strongly recommended. We want perpetual-flowering Roses very badly.

Pink Pearl (Hobbies, 1912).—This has Irish Elegance for one of its parents, and it has retained some of the beauty of its parent. It is not quite single, but makes a very effective pillar when fully out.

Sheilagh Wilson, Hybrid Tea (Paul and Son, 1912).—This is a very lovely single; a semi-climber that flowers again in the autumn; but so far with me is neither very vigorous nor very free-flowering. But the plants are young yet, and may improve in both aspects.

The award was unanimous. The accompanying illustration will give some idea of the erect character of the stems and the graceful poise of the flowers. From the St. George's Nursery Company, Harlington, Middlesex.

NEW ORCHIDS.

Cypripedium Julian.—A flower of remarkably good form, with a broad, overarching dorsal. Parentage: Vandyke × Ædippe. The general colour is greenish brown, the dorsal being white suffused with rosy pink. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O. First-class certificate.

Awards of merit were given to the following: *Odontoglossum illustrissimum* The Dell Variety, sent by Baron Bruno Schröder; *Odontioda* Royal Gem Westonbirt Variety, from Lieutenant-Colonel

THE PERENNIAL STOCKS.

THE *Matthiolas* are interesting plants which belong to the Mediterranean regions; there are three or four dozen different kinds, half of them being annual or biennial. Of the perennial ones, the following are grown in alpine gardens:

Matthiola fenestralis, growing wild on the sea rocks of the island Cretica, and nowhere else. It seems to be a dwarf form of *M. incana* (one of the ancestors of the common Stock), with thick, undulate and spirally rolled leaves, deep carmine petals and very thick siliquæ. In Cretica the people grow this plant in pots in their windows; hence its name *fenestralis*. It is half-hardy with us (at *Floraire* we have to cover it through the winter), and wants a dry place in the full sun.

M. sinuata, well known by everybody who ever saw the Mediterranean coasts, and generally considered as a biennial, although it, in certain conditions, proves to be quite perennial. The plant, Mediterranean by its origin, grows wild at the ocean coast, and goes so far as England. It is a sweet-scented plant, the flowers of it being light lilac and expending a delicious fragrance, but only in the evening and in the night.

M. Aristis is a curious plant, rather rarely found, growing wild here and there in the South of France, in Spain and Portugal, in Sicily, in Greece and in North Africa. I found it once in my life in the very beautiful Gorges du Verdon in the Var. It grows there in the white and barren sandy loam at very sunny places, and is the only plant growing in it. Very cæspitose, of stoloniferous nature, with dark green, somewhat greyish, dentate leaves; flowers in large spikes, dull purple, and without any smell, so far as I know. At *Floraire* we grow it on the top of our wall, and it flourishes there and gives good seeds.

M. varia is near to it and is a child of Greece, where it grows near the sea-coasts. It is a stoloniferous kind, too, and has large light, purple flowers.

M. valesiaca* and *M. pedemontana are near to it, but very different in their requirements; they are really

wall plants, and the most stoloniferous of all. The first is the rare plant of the Simplon Road in Valais; it is found still in the very near valley of Binn, and, further to the East, near the Lago d'Garda, where I was very surprised last July to find my country plant, which I thought was a true Swiss child, growing between the rocks of Tremonie and near Riva. The plant is a delightful one, very creeping, its long and slender rootstock bearing its new rosettes everywhere. Sometimes *M. valesiaca* covers an area of several mètres in a rockery. It is a plant for the moraine, in the true sense of the word, or for the wall garden. The foliage of *M. valesiaca* is silvery grey, and the flowers of a reddish purple. *M. pedemontana* differs from it by its slenderer growth, its leaves narrower and thinner, and its flowers greenish brown, of a very rare and curious colour. It needs the same culture as *M. valesiaca*.

Floraire, Geneva.

H. CORREVON.

NEW CYCLAMEN MRS. L. M. GREAVES. THIS OBTAINED AN AWARD OF MERIT LAST WEEK.

Thelma (W. Spooner, 1912).—A very effective and bright colour, with delightful single flowers. The plant is vigorous and the flowers are large for a single. A Rose of much promise.

Southampton.

HERBERT E. MOLYNEUX.

NEW AND RARE PLANTS.

Cyclamen Mrs. L. M. Greaves.—Departing from its usual custom, the floral committee gave this distinct and good sort an award of merit as a named variety, thus stamping it as one of unusual excellence. The colour is rich and deep—cerise, with a suffusion of salmon—and unlike anything before known in the Cyclamen. The foliage is slightly marbled. All the plants shown were true to their kind, thus demonstrating that the variety comes practically true from seeds

Sir George Holford; *Odontoglossum* Canary and *Cymbidium* Schlegeleri punctatum, from Pantia Ralli, Esq.; and *Cymbidium* coningsbyanum, shown by Mr. G. Hamilton Smith.

NEW FRUIT.

Citrus japonica.—The value of this species is ornamental rather than useful. The fruits, which are about the size of Walnuts, are lemon colour and almost spherical. Several plants about two feet high, carrying heavy crops, were shown, and were evidence of their usefulness for decorative purposes. When quite ripe the fruits are pleasant to the palate. Exhibited by Messrs. James Veitch and Sons, Limited. Award of merit.

The foregoing plants were granted awards by the Royal Horticultural Society on January 13.

GARDENING FOR BEGINNERS.

HOW TO GROW EARLY TOMATOES.

WHERE there are suitable structures and plenty of artificial heat, very little difficulty need be experienced in the growing of very fine crops of Tomatoes.

This condition obtains, of course, where experienced cultivators are concerned. In ordinary circumstances the general cultivator

pulling it in pieces, and some half-decayed leaf-soil passed through an inch mesh sieve. Stack this compost in a cool shed, or, if in the open, cover the heap to keep off rain until required for use. The compost for the seeds should be of a similar quality, but much finer. Use pots or pans in which to sow the seeds. Always remember that Tomatoes thrive best in a very warm, sunny position. If such be available now, raise the seedlings in it.

How to Raise the Seedlings.—Fill pots or pans as shown in Fig. A at No. 1, which denotes drainage and coarse material such as leaves and rough, turfy compost; No. 2, a layer of finer compost; and No. 3, the seeds lightly covered. As stated above, place the seed-pots on a stage in a warm position and keep the soil in a moist state, but never very wet, else the seeds will decay and not germinate. All necessary moisture should be afforded by holding the pot in a vessel of tepid water until the surface of the soil becomes dark; then gently lift the pot. Probably only one watering will be needed, as the seeds germinate in a few days where there is enough heat and moisture. A sheet of glass may be placed on the pot to conserve moisture until the seedlings break through; then it must be removed, but it is not advisable to put brown paper or moss on the glass. The young plants must be brought on as steadily as possible. When the seedlings are at the stage shown at No. 4, lift and transplant them 3 inches apart each way in pans or boxes. At the stage shown at No. 5, transfer them to small pots, No. 6.

The Training of the Young Plants.—From this stage onwards side shoots will grow freely, but they must not be left on to attain to a length beyond an inch or so. On the young plant, No. 7, these side shoots are shown at Nos. 8, 8. From the 5-inch pots the plants must be shifted to those in which they are to fruit, or to the boxes or restricted beds, as it is good policy to restrict the roots to a given space, especially in the case of the earliest crop.

Positions in which to Fruit the Plants.—There is much available space in many green-houses and small structures that might be used if some staging of a temporary character were erected. No. 1 in Fig. B shows how the plants may be grown in a deep, heated pit. Other kinds of plants may be grown in the same structure if the Tomatoes are trained 3 feet apart. In many lean-to houses there is some wall space on the back wall above the stage, and quite a number of plants may be grown and trained there, as shown at Nos. 2 and 3. Of course, there is always that good position at the front of the house where there is generally room for a few plants on the stage, No. 4. Grow the plants in a rich, fibrous loam, made moderately firm. A sandy loam needs no sand, but a retentive one requires sand and leaf-soil. When two or three trusses of fruit have set and are swelling freely, top-dress the soil, as shown at No. 5, and feed the plants with liquid manures and approved chemicals.

CINDERS AND CEMENT FOR GARDEN PATHS.

It is always a pleasure to walk on a firm, dry path. One often sees new paths made by the laying down of a thin coating of rather rough gravel. A path of this kind is never satisfactory. If the

rough gravel is laid thick enough and then properly surfaced with finer gravel, the path will be improved as time passes; but so many lovers of gardens are not able to procure good gravel without going to considerable expense. I am now referring to gardens in town and suburban districts. In many of them cinders are plentiful, and both the cinders and cement can be obtained without much trouble or expense.

Mark out the space for the path and remove the soil to a depth of 5 inches; then put in the roughest cinders to a depth of 3 inches, and water them so that they can be easily firmed and provide a good base for the cinders and cement. Place some fine sifted cinders in a bucket, add pure cement to the extent of one-third the bulk (do not use any sand), and then pour in water, mixing the cement and cinders until the mixture is of the consistency of mortar. With the aid of a bricklayer's trowel spread out the mixture to a depth of 2 inches, leaving an even surface. On the latter sprinkle at once a few dry cinders, and gently press them in with the back of a garden spade. The surface will not then be slippery; the general appearance will be pleasing and the path lasting. No weeding of paths will be necessary. Do not use the cement in frosty weather.

SHAMROCK.

A

RAISING TOMATOES FROM SEEDS, AND SHOWING HOW TO POT THEM OFF.

can secure a medium crop. We, however, wish the beginner to succeed in growing a big crop. Usually, early in the season there is considerable loss through failing to get the first-formed trusses of fruits to set. It is quite time now to make a beginning by sowing seeds and preparing generally for the due potting or boxing of the resultant plants.

The Best Soil.—Some inexperienced cultivators believe that the wisest course to follow is to grow the plants in a poor soil. Now, if we were intending to grow them in a deep border in the open air, or even under glass, we would prefer a poor rooting medium to a rich one; but as the bulk of soil is comparatively small, confined as it will be in flower-pots or narrow, shallow boxes, it ought to be of very good quality. To this end prepare some very fibrous loam by

B

SHOWING POSITIONS IN WHICH THE PLANTS MAY BE GROWN

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Early Permanent Vines will now be in flower, and consequently less atmospheric moisture will be necessary. Shake the trellis several times during the early part of the day in order to distribute the pollen, and do not allow the foliage to come in contact with the glass, but direct the shoots gradually towards the trellis a little at a time. At this stage a night temperature of 70° may be allowed while the weather is mild; but if cold weather sets in, it is better to drop the temperature to 65° than to employ too much fire-heat to keep it up, and during bright days the temperature may be allowed to rise to 90° by sunheat. Ventilation must be given with great care and only at the top of the house, and this should never be applied with a view to lowering the temperature.

Early Peaches and Nectarines in Pots.—The mild weather has been all in favour of forcing, and the early trees will now have set their fruits. Do not attempt to thin the fruits much at present, but leave all on the upper side of the branches for another ten days. In disbudding, which should be done a little at a time, leave a well-placed shoot as near the base of the branch as possible, with one or two on the sides of the branches, which may afterwards be shortened back to two or three leaves, in order to form young spurs for another season's crop. Great care is necessary in watering these trees that the soil does not become sour, or many of the fruits will drop. A night temperature of 55° will be quite high enough for the present. Syringe the trees lightly on bright days, and keep a careful watch for green or black fly, which may be kept in check by the use of a little Quassia Extract while syringing the trees in the afternoon.

The Orchard-House.—The trees in this house must be started into growth with care. They should never be excited by much fire-heat until the flowering period is over, or weak flowers and an inferior set of fruit will be the result. If the trees are potted in suitable soil, no manure-water will be necessary until the fruits are set. Syringe the walls and floor of the house to promote a moist atmosphere. A temperature of 50° at night in mild weather is quite high enough.

Plants Under Glass.

Smilax.—In order to produce Smilax in quantity for decoration, seeds should be sown now in pans of fine sifted soil, covered lightly and placed on a hot-bed. When large enough to handle, the seedlings should be potted into 2½-inch pots and afterwards into 3-inch pots, growing them in a temperature of 70°. At Frogmore these plants are trained to green string on the back wall of a vinery or Peach-house, and planted in a compost of loam and leaf-soil with sufficient sand to keep the soil in a porous condition.

Asparagus Sprengeri may also be sown now and treated in the same way until the plants are finally placed in large baskets and hung in a warm Palm-house or conservatory. When well established in the baskets, the roots may be frequently soaked with weak liquid manure. The greatest danger to these plants is want of water at the roots.

The Flower Garden.

Cold Pits containing autumn-struck plants of Calceolarias, Pentstemons, &c., should be freely ventilated to keep the plants from becoming drawn. Pinch the tops out of Pentstemon plants to encourage side shoots, and when these have become prominent the plants may be potted into 4-inch pots and grown near the glass in the same pit. Calceolarias may be treated in a similar way; but if standard plants of *C. amplexicaulis* are required, they must be grown on single stems until they reach the necessary height, when the tops must be removed.

Marguerites and Heliotrope struck in September should be potted without delay and placed in gentle heat. If the plants have become drawn, they should be cut back and allowed to remain until side shoots appear before they are potted.

Lobelia cardinalis Victoria.—This beautiful perennial, with its dark metallic foliage and bright

scarlet flowers, may easily be increased by division of the roots now. These may be potted into 3-inch pots and grown on a bed of ashes in a cold pit, or seeds may be sown now and placed over a gentle bottom-heat. If potted up as soon as ready, they will make nice plants for bedding out in May, and should flower in the month of August.

The Hardy Fruit Garden.

Orchard Fruit Trees.—All new plantations should be finished as soon as possible. Each standard tree will require a strong stake as soon as planted, and if sharp frost or drying wind should prevail, a mulching of some kind should be placed over the roots. In exposed positions the stems may be protected by hay-bands to prevent evaporation.

The Kitchen Garden.

Large Onions.—If large Onions are required, the seeds should be sown about the end of January. Sow in boxes of fine soil and place them in a slightly heated pit. The soil may consist of good sandy loam and leaf-soil, and should be pressed tightly into the boxes. Sow the seeds thinly, and as soon as the plants appear they should be given sufficient air to keep them stocky.

Leeks may also be sown now and placed in the same pit for the time being.

Seakale.—Roots intended for forcing should be lifted at once and placed behind a north wall. These roots should be put in an upright position and covered with soil until required for forcing. As this work proceeds, sufficient clean thongs should be selected for the propagation of next season's plants. These cuttings may be placed in a horizontal position, quite close together, and covered with 4 inches of sandy soil. By April they will be ready for planting out.

Peas in Pots.—An occasional dish of Peas may be obtained by sowing in pots at frequent intervals from now until the end of February. Eight-inch pots are large enough, and the soil may consist of three parts rich loam and one part decayed manure. A well-ventilated house or pit is necessary.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Horse-Radish.—As a rule, Horse-radish is generally grown in the most out-of-the-way part of the garden, and perhaps for many reasons this is as it should be, as it is neither fastidious as to soil nor situation. At the same time, it will pay to give it a little more attention than it usually receives. Now is a good time to make a new plantation, and in doing so have the ground trenched two spits deep, adding some well-rotted manure. In planting, see that the crowns are placed at least 4 inches or 5 inches deep. If time permits, it is well to replant each year.

Broad Beans.—If a sowing of Broad Beans was not made in the late autumn, no time should be lost in putting in a few rows for an early supply. The seeds should be sown in a fairly moist part of the garden, as the plants will not stand drought. To guard against mice, rub the seeds over with red lead, or stand them for a few hours in paraffin before sowing.

Peas.—It is still too early to sow Peas out of doors, at least in the colder climate of the North, but a sowing might well be made now either in pots, cutting-boxes or strips of turf and placed in a cold frame. Some early dwarf variety, such as English Wonder, is best suited for this sowing.

Dwarf Beans.—A dish of Dwarf Beans is usually very much prized in the early spring. A sowing made now will, for ordinary purposes, be early enough. A number of pots may be sown and placed in a brisk heat; the seeds would, of course, do equally well in long, narrow boxes. Last season I grew this batch in ordinary Tomato boxes, with very good results. Water should be given very sparingly at first, otherwise the young growths turn yellow, which will spell failure.

Autumn-Planted Cabbage.—On an early border autumn-planted Cabbage will be all the better for a slight dressing of sulphate of ammonia between the drills if the weather is favourable. An open handful to every 3 yards is sufficient. Afterwards run the Dutch hoe between the rows.

Mushrooms.—These may be had almost all the year round, provided one possesses the necessary accommodation. Those, of course, who only possess a single house have to be content with a crop occasionally. Still, it is surprising what results one can get by making up a bed in odd corners, provided the place selected can be kept at an even temperature without the aid of fire-heat. Collect sufficient horse-manure as will make up a bed (not an easy matter in these days of motors), place in a dry, open shed, and turn every day for about a fortnight. When sufficiently dry, throw into a heap. For a number of years I have mixed a fair quantity of dry leaves with the manure before making up the bed, which, I think, tends to preserve the heat. In making up the bed, distribute the manure evenly over the surface and tread it firmly. The temperature will rise very rapidly, and the bed may be spawned when it has dropped below 90°.

The Flower Garden.

Sweet Peas.—Sow the main batch of Sweet Peas now either in boxes or pots and place them in a cold frame. This method of raising Sweet Peas is becoming more popular each year, and to my mind rightly so. It is a fact that with proper management they can be had in bloom as long from a sowing made now as they can from one made out of doors in March. It is a good plan to chip the seeds of very scarce varieties to ensure germination. Previous to placing them in the frame, give the surface a good dressing of soot, as slugs play great havoc just as the seedlings are pushing through the soil.

Delphinium Belladonna, if sown in mild heat now, will bloom in the late summer and early autumn. It is a lovely shade of blue, and is sure to give the greatest satisfaction to all who grow it. Last season I planted it with Sutton's Blue Nemesis, and it was greatly admired.

Spiraea ariæfolia.—One could scarcely imagine anything more handsome than a few plants of *Spiraea ariæfolia* dotted through the border. All these ought to be planted now, for if done later they do not start away so readily.

Plants Under Glass.

Crotons.—Cuttings may now be put in the propagating-case. Ring those plants that have grown rather tall.

Dracænas.—Those who wish to increase the stock of *Dracænas* may do so now by cutting up the stem into pieces about an inch long. Place them in shallow pans, and keep them where they will have the benefit of a brisk bottom-heat.

Gloxinias.—If a sowing of Gloxinias is made now, the young plants will bloom in the late summer, which will add a nice bit of colour, either for furnishing stands indoors or placing among the *Adiantums* in the fernery.

Carnations.—Soil should now be prepared for potting on the young Malmaisons layered in the autumn. It is always wise to have the soil prepared some little time beforehand, and in doing so add a 6-inch potful of hot lime to each barrow-load of soil, and turn frequently.

Cypripediums.—The present will be a suitable time to look over the *Cypripediums*, and any that show signs of going back may be shaken out and repotted in a mixture of good fibrous loam, peat and sphagnum moss. Others may only require top-dressing. In either case water very carefully at this stage.

Fruits Under Glass.

Vines.—Attend carefully to disbudding Vines that were started in late December. This work should be done very gradually and by an experienced person. In a number of cases two shoots should be left to the spur until one is able to see which is showing the better bunch. On fine days, and when much heat is used, keep a good deal of moisture about; but discontinue syringing the Vines.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON
SWEET PEAS.

FROM the present time and onwards the Sweet Pea enthusiast knows no idle moment. Each week, as it comes round, brings its own particular needs, and if fine exhibition blooms be the desired goal, then the grower must give careful attention to every detail in the cultivation of his plants.

Ordering Seed.—Long before these notes appear the real enthusiastic Sweet Pea grower will have procured his seed, and if he be a devotee to autumn sowing, his seedlings will be requiring attention. But procrastination always holds a firm grip on some people, and to them delay in purchasing seeds is deadly dangerous. For several years the seasons have been bad and the crops small; and although one may hope that the past season may be the last of these lean years, yet both buyer and seedsman must suffer, for the supply cannot equal the demand, and the buyer receives less seed for his money. However, so far as reports can be relied upon, the shortage of seed this year is slightly compensated by the excellent germinating quality of the seeds. Intending growers, therefore, should immediately peruse the advertisement columns of THE GARDEN, in which several reliable seedsmen are advertising, and, a choice having been made, an order should be despatched without further delay. In previous notes contained in the issues of THE GARDEN for December 20, 1913, and January 3, 1914, lists of varieties suited for exhibition and garden purposes respectively were given, and a reference to these will make a selection more easy. I would recommend that several extra varieties be named as substitutes, for in all probability many varieties will have been sold out because of the general shortage of seed, and especially that of the newer varieties.

Preparation of the Ground.—The ground should have been prepared in the autumn, but if circumstances have prevented this work being done, then as soon as possible it should be deeply and well cultivated, incorporating into it good decomposed manure. Allow the soil to settle down before planting, for loose soil is detrimental to successful growing of Sweet Peas.

Seed-Sowing.—This may be done any time from the present, just when the opportunity suits the particular grower. Plant either in pots or boxes in rows; in many instances, where the grower cannot give daily attention, the Sweet Peas thrive best in boxes, which have less chance of getting dry and thus checking regular growth. Sheets of paper or glass placed over the boxes or pots assist germination, and directly the seedlings appear these should be taken off and the plants well exposed to the light, encouraging throughout a slow, sturdy growth. For the seedlings from an autumn sowing a potting on will be beneficial, and they should be pinched (if not already done) to cause new growths from the base. "Potting on" may seem rather a tall order, but the increased vigour resultant from so doing fully compensates for the labour it necessitates. After repotting, if the plants are in frames, it is advisable to keep them fairly close for a few days, and, of course, protect them by coverings on frosty nights.

Labels.—Where these are used (and most growers are kind to their novice friends by labelling

their Sweet Peas) it will be well to utilise any odd moments in preparing them, for little time can be spared later on in the spring for this important work. Referring to names and their multiplicity, one of the pleasing features in many catalogues received is the attempt to obviate this difficulty by carefully arranged lists of best varieties. The catalogue of Hallams, Moseley, Birmingham, is excellent in this respect, and forms a most useful guide, especially for amateurs, who are generally the chief sufferers, often buying the same variety under various names. That of Robert Sydenham, Limited, Tenby Street, Birmingham, is also good, having a well-arranged alphabetical list of the best sorts, from which a selection can easily be made; while their presentation coloured plate of Sweet Peas Barbara, Princess Mary, Zarina Spencer and Edith Taylor well illustrates these good varieties. Dobbie and Co., Edinburgh, the well-known Sweet Pea firm, give excellent and full cultural notes in their catalogue, a delightful production replete with useful information on all matters connected with the garden, and well on a par with other specialities sent out by this noted firm. Space prevents more than a mere mentioning of the catalogues of Unwin, Dipnall, Bide, and Deal, each full of interest, and I close these notes with congratulations to those seedsmen who have endeavoured to meet and overcome the difficulties that have hindered the progress of the Sweet Pea, and wish them success in the coming season.

S. M. CROW.

A FINE APPLE ORCHARD.

NOW that more interest is being taken in Apple-growing in this country, it is just as well to look about and note the most approved methods of cultivation before embarking on the subject, either for profit or home consumption; and as the old-fashioned orchard on grass has still many adherents, I will briefly describe the result of high-class cultivation as practised at Aldenham House, Elstree. I perhaps know more about the gardens at Aldenham than the majority of visitors, as it has been my pleasure during the last twenty-five years to pay at least an annual visit of some days and, naturally, I note what my good friend, Mr. Beckett, does in the way of extending these princely gardens in obedience to the wish of his enthusiastic employer, the Hon. Vicary Gibbs.

As the season for planting Apple trees is still with us, I thought these notes would help intending planters. The orchard in question occupies some ten acres and is all on grass; originally it was but half the size. The trees are wholly of the standard or half-standard type. Half the trees were planted thirty-seven years ago, but were not a success, and as the subsoil naturally at Aldenham is clay, it was suspected that the rooting conditions were unfavourable. It was decided to replant the trees and add more land to the orchard. Thus, in the year 1886 the work of renovation was begun, this being completed the following year. The land was thoroughly drained and entirely trenched from 3 feet to 4 feet deep, adding any lightening material available, such as burnt earth, to render the soil porous and naturally warmer. The trees were replanted, allowing abundant space between them and as much as 50 feet between the rows. The trees were annually and carefully pruned with a view to obtaining as large an area as possible, at the same time keeping the

branches thin and allowing plenty of light in the centre of the trees. The trees were carefully attended to in regard to insect pests, lichen and so forth. Singular to say, the latter is not very troublesome, owing, no doubt, to the favourable rooting conditions and perfect drainage. In many orchards the excessive crops of moss and lichen present are traceable to the unsuitable subsoil, which is, in some cases, so impervious that water from excessive rains cannot quickly get away, thus causing stagnation of the roots.

Below I give the names of some of the larger trees, with their spread of branch and approximate crops of fruit last season. Nowhere have I seen Wellington succeed better than here. The trees grow freely and crop annually, giving handsome, clean fruits, which keep remarkably well, thus displaying this valuable Apple at its best. Cox's Orange Pippin is a fine tree, in spite of the assertion of some writers that this Apple as a standard is not a success, although last year it did not carry a large crop. Hambledon Deux Ans, Small's Admirable, Lord Derby and a special form of Blenheim Pippin are a special success. New varieties are added as they appear.

Variety of Fruit.	Circumference of Branches. Feet.	Quantity of Fruit. Bushels.
Blenheim Pippin	102	18
Bramley's Seedling	87	12
Fearn's Pippin	86	16
Cox's Orange Pippin	78	8
Golden Noble	81	12
Gascoyne's Seedling	97	8
Hambledon Deux Ans	103	8
King of Tompkins' County	90	6
Lord Derby	94	27
Small's Admirable	87	20
Mère du Ménage	66	18
Tower of Glamis	84	12

GARDENING ACROSTICS.

DOUBLE ACROSTIC No. 8.

- Firsts.—A celebrated Dutch florist of the eighteenth century (his surname).
Lasts.—The flower which he improved.
1. A horticultural distinction.
2. Found in compound words, denoting sharp or acid.
3. A tribute of Regel to a Russian brother botanist.
4. A good early Plum.
5. Sunflowers.
6. An Auricula man of a century ago (surname).
7. A retarding influence.
8. I look like what I am popularly called, but not like what I am.

Solutions of the foregoing must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C, not later than the first post on Saturday, January 31. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF
ACROSTIC No. 6.

CONRAD—GESNER.

- * 1. C ORN-FLA G
- † 2. O VUL E
- ‡ 3. N EPHROLEPI S
- § 4. R AMPIO N
- || 5. A PPL E
- ¶ 6. D EODA R

Conrad Gesner, born in 1516 at Zurich, has been called the Pliny of his time. He published a

"Historia Animalium," and at the time of his death he had collected 1,500 drawings for a history of plants. He died of the plague in his forty-ninth year.—Arber's "Herbals," pages 90 to 93. * Corn-flag is given in all gardening books as the English name for the *Gladiolus*. † The ovule after fertilisation develops into the seed. ‡ Nephros, of which *Nephrolepis* is compounded, is the Greek word for kidney. The coverings of the sori are more or less kidney-shaped. § *Campanula Rapunculus*. Rapa is a small Turnip. Prior gives the derivation of Rampion from the French "raiponce," to which "m" has been added for the sake of euphony.—Prior's "Popular Names of British Plants." || See Richard Folkard's "Plant Lore." No fruit, he says, is so famous in fable and history as the Apple. In Britain it gave its name to the "Isle of the Blest" (= Avalon), and in Saxon times one of the Coronation prayers was "that this land may be filled with Apples." ¶ *Cedrus Deodara*, or the Indian Cedar, a native of the Himalaya, is frequently mentioned in old Indian hymns and poems. On account of its graceful habit it is a favourite tree for ornamental planting. We speak of it as the Deodar.

RESULT OF ACROSTIC No. 6.

In this acrostic it was possible to obtain eight marks, one for each correct "first" and "last," and one for each correct light. The following have been awarded:

Eight marks.—R. Chapman, M. Browne, "Jan," "Tempus Fugit," N. E. Hadden, W. J. Wigston, "Shamrock," G. D. King, "Brixtonian," "Penwarne," "Bow," "Rusticus," "St. Kevins," "Ping," "Elm," "Nautilus," W. Bond, "Johnny Crow," L. Biggwith, "Miller," "Hero," Ernest Ballard and "W. R. D."

Seven marks.—"Westbank," "Bees-Wing," Wm. Slocombe, "Rustic," "White Lady," "M. M.," "Boarsvale," "Scotia" and A. Henderson.

Six marks.—Miss G. H. Jeffreys and H. J. Giblett.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

WATER LILY POOLS (H. F. M.).—It is quite natural for the leaves of your Water Lilies to die in the winter. The opportunity should be taken to clean out the tanks while the plants are at rest. Remove all mud and give new soil if necessary. Scrub the sides of the tanks and make everything as clean as possible. You will doubtless obtain flowers next summer. In the event of the green scum growing next summer, add copper sulphate to the water at the rate of one part of the chemical to 1,000,000 parts of water. If you calculate the cubic capacity of the tanks and then assume that each cubic foot of water weighs 62½ lb., you can easily ascertain the correct amount of copper sulphate to use. Tie the

copper sulphate in canvas, and draw it about in the water until dissolved. Two or more applications may be necessary during the summer.

SMALL VIOLETS (C. E. F. M.).—There is nothing about the flowers sent to account for their small size. Perhaps the plants are fed too well with nitrogenous food, or kept a little too dry, or belong to a poor strain. But there may be something wrong with the plants. The material sent is too scrappy to enable us to say.

HERBACEOUS LOBELIAS (P. H. J.).—The nearest approach to crimson in these is in the variety *Queen Victoria*, which is more scarlet than crimson. *Cardinalis* and *Firefly* also have brilliantly coloured flowers. If the pots were of reasonable size, say, 6 inches to 9 inches across, the plants would do quite well plunged in the bog-bed as you suggest, though we should expect to find them quite hardy if planted out in your district. The plunging in pots, however, is not essential, as the plants move quite safely if lifted with a small ball of earth. Even if a few were lost, they are easily reproduced by means of seeds, and these, if sown in January, make flowering plants in the same year if given liberal treatment. Hardy Orchids suitable for the bog-bed should include *Cypripedium spectabile*, *C. pubescens*, *C. parviflorum*, *C. montanum* and *C. Calceolus*. To these should be added *Orchis foliosa*, *O. latifolia*, *O. maculata*, *O. Mascula* and *O. purpurea*, all of which are interesting and beautiful.

TREES AND SHRUBS.

MYRTUS UGNI AND RED BERRIES (S. S.).—The shrubs sent are correctly named *Myrtus communis* and *M. Ugni*. The latter plant is also referred to as *Eugenia Ugni* perhaps more frequently than *M. Ugni*. The red berries are quite correct for this species. Black fruits are borne by a closely allied species which is sometimes confused with *M. Ugni*.

SHRUBS TO COVER FENCE (J. H.).—The following plants are suitable for your purpose: *Escallonia langleyensis*, *Solanum jasminoides*, *Ceanothus veitchianus*, *Jasminum nudiflorum*, *Rubus bambusarum*, *Solanum crispum*, *Berberidopsis corallina*, *Rosa bracteata* and *Vitis Cignetiae*. The first named should be given a prominent position, for it is evergreen and very showy. All are, however, of first-rate worth. Those which are not strictly climbing plants will answer very well for your purpose. The majority are evergreen.

EUONYMUS LEAVES COVERED WITH WHITE SPOTS (Lady B.).—Your plants of *Euonymus* are evidently infested with the *Euonymus* mildew, a fungus known to scientists as *Oidium Euonymi japonicae*. This disease is very prevalent in the South of England and in some parts of Southern Europe. When a few leaves only are affected, it is a good plan to remove and burn the infested shoots. When, however, the trouble is deeply rooted, the plants should be cut well back, taking care to burn the prunings immediately, and they should then be dusted over with flowers of sulphur when the leaves are moist with dew. The dusting may be necessary on two or three occasions. The plants may also be sponged with Bordeaux mixture during the spring, or at the time when the young leaves are emerging from the bud stage. This will have the effect of killing the resting spores which have been dormant during the winter.

PLANTING SHRUBS (Bicknoller).—If you have room, you would do better to form a shrubbery to block out the adjoining garden, rather than plant a hedge for the purpose. Such shrubs as *Lilacs*, *Viburnum Opulus* sterile, *Philadelphus coronarius*, *P. grandiflora*, *Berberis stenophylla*, *B. Darwinii*, *Hollies*, *Pyrus floribunda* and *Deutzia crenata*, with a few standard flowering trees, such as *Double Scarlet Thorn*, *Pyrus spectabilis*, *Laburnum alpinum*, *Prunus Avium flore pleno* and *P. serrulata*, would grow up quickly and provide an effective screen. If, however, a fence is necessary, you can do as you say, build one of split Pine poles, then cover it with *Escallonia langleyensis*. This plant will eventually cover a fence 8 feet high, and will provide as dense a hedge as you desire. Moreover, it blossoms freely during the summer. It would be more satisfactory to cover the fence with one plant rather than with a variety, as you would then obtain a more uniform screen. The quickest-growing hedge you could plant would be common Oval-leaved Privet, but it is a most uninteresting shrub, and you would doubtless tire of it in a short time.

THE GREENHOUSE.

PLANTS FOR WINDOW CASE (Gerard).—If the weather is very severe, it will be a good plan to protect your case with a covering of some kind; if of a woolly texture, so much the better. This, of course, will only be necessary in the event of severe frost. Provided you have ample means of ventilation, the various summer-flowering subjects may well be grown in such a structure. *Petunias* would do well therein, and also *Fuchsias*, while perhaps the most desirable things of all for the purpose would be tuberous-rooted *Begonias*.

TREATMENT OF HYDRANGEAS, KENTIAS AND CYRTOMIUMS (L.).—We should not advise you to cut back your plants of *Hydrangea* *Mme. Moulière* now, as the prominent terminal buds will contain the future flowers in embryo. Any cutting back required should be done as soon as the flowers are over, and, directly new shoots are pushed out, the plants must be repotted if they require it. When the pots are full of roots, an occasional stimulant will be beneficial. If the cuttings of last spring had been in an ordinary frame, they should have lost their leaves, so we presume that you have kept them rather

warmer. *Hydrangeas* only need to be just protected from the frost. Your *Kentias* and *Cyrtomiums* have very probably been allowed to get too dry, while, on the other hand, the trouble may be owing to an excess of moisture. If the roots are in good condition, an occasional dose of one of the many concentrated plant foods now on the market should restore them to their normal colour.

ROSE GARDEN.

ROSES AND SAWFLY (A Constant Reader).—You may safely apply some manure now, but we should advise you to have this lightly forked beneath the soil. The lime may be scattered about and also worked into the soil. You can spray with the insecticide as usual, but we would advise some applications of nicotine wash or Hellebore wash, as this is the best remedy for the sawfly. Be careful to spray beneath the foliage during April, May and June. This sawfly, which so badly disfigures the foliage of our Roses and is known as Rose slugworm, may readily be overcome if careful and persistent spraying with the washes named is carried out.

FLOWERING PERIOD OF VARIOUS RAMBLERS (Enquirers).—The varieties marked with an asterisk would last in bloom about three weeks, the others from four to five weeks. Those marked "again in autumn" would give a few blooms at that season of the year. June 10—**Alberic Barbier* (again in autumn). June 15—**Euphrosyne*, **Goldfinch*, **René André*, *Trier* (Perpetual). **Paul Transon* (again in autumn), **Tausendschön*, **Tea Rambler* and *Flower of Fairfield* (Perpetual). June 25—**Veilchenblau*, *Aviateur Blériot* and *Juliet* (again in autumn). July 1—**Crimson Rambler*, **Félicité Perpétue*, **Blush Rambler* and **Starlight*. July 10—**American Pillar*. July 20—*Dorothy Perkins* (again in autumn), *White Dorothy* (again in autumn), *Coquina*, *Excelsa* (again in autumn) and *Hiawatha* (again in autumn).

ARCHES OF ROSES TO BLOOM CONTINUOUSLY (E. T. M.).—You could plant an early and a late blooming Rose together. This is often done; for instance, *Carmine Pillar* to bloom early, and *Aimée Vibert* late. If you plant *wichuraiana* Roses, you will find the date of flowering given in some lists. *Jersey Beauty* would flower early, and *Excelsa* late. By keeping the growths of each well reduced, there would be no overcrowding. Certainly you could plant *Wistaria* as you suggest, and the effect would be very pleasing. There are other subjects, such as *Clematises*, *Loniceras*, *Laburnums*, &c., that will all help to make a pergola most interesting; in fact, one may have something nearly always in bloom by judicious selection. *Berberis Darwinii* makes a fine hedge, and it grows freely. *Veronica Traversii* is rather slow. You would find *Osmanthus ilicifolius* a quicker grower than *Holly* and not so expensive. *Rose American Pillar* makes a delightful hedge plant, and it is almost evergreen. By putting down a few posts and wires you would soon have a good 7-feet to 8-feet hedge, or taller if desired.

FRUIT GARDEN.

PEACH TREES (S. R. B.).—Glass protectors to Peach walls should be placed in position before the trees come into bloom (say, the end of this month), and allowed to remain on till the fruit is set and danger of frost is passed.

GRAFTED TREES: APPLE KING OF THE PIPPINS (C. W. B.).—(1) Three scions in each graft would be quite sufficient to leave, selecting those best placed for future growth. (2) Roses potted up in December would be better planted in their quarters about the second week in February.

ABOUT PLANTING VINES (R. W. R.).—It is a pity to take out the variety *Alicante*, as it is one of the best to grow, crops heavily and keeps well generally. If the roots are well fed and the Vines are not overcropped, the berries will not shank. All late varieties should be ripe by October 1 to keep well. If ripened much later, they neither colour well nor ripen. The following are five good varieties to grow, although for general use *Black Hamburg* is not excelled by any other: *Foster's Seedling*, free cropping, easy to manage, keeps well; *Madresfield Court*, heavy cropper, *Muscat flavour*; *Appley Towers*, a grand late sort; *Gros Colman*, large berries and bunches, free cropping, hangs on Vines late; and *Lady Hutt*, a late white, free cropper, sets berries well, strong growing, and keeps until the new year. No white excels the *Muscat of Alexandria*, but it is best grown in a house by itself and given special treatment. Messrs. J. R. Pearson and Sons of Lowdham, Notts, make a speciality of Vines in pots.

MISCELLANEOUS.

GRUBS OF THE SWIFT MOTH (F. M. C.).—The grubs are those of the swift moth, which is a troublesome pest of a large number of plants, devouring any fleshy roots almost indiscriminately. It would be well to turn up any ground near by roughly, so that birds can get at the grubs, for starlings and some other birds are very fond of them. Vaporite or some other soil fumigant may, perhaps, help to drive them away.

LIME AND MANURE (Kent).—No harm should follow the treatment you adopted in liming the new soil and subsequently mixing well-manured earth with it; quite the contrary. Loss of ammonia follows mixing lime and manure before they are put into the earth, but not after, for the soil will absorb any ammonia liberated. Your treatment of the soil appears to have been admirable for the purpose of growing shrubs, and the only addition we can suggest is that of basic slag at the rate of about four ounces to the square yard.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

To Our Readers.—We shall be glad if any reader who experiences difficulty in obtaining **THE GARDEN** from newsagents will send us particulars.

Starting Fuchsias.—Plants that have been stored for the winter may now be gone over and pruned, and before placing them in any of the houses, examine them carefully for mealy bug. Where some of the older plants have become unsightly, it is a good plan to cut them back almost to the pot, when they will break and make good furnishing plants.

Flowers Visited by Humming-Birds.—The bright red flowers of *Erythrina Crista-galli* are inverted, the wings are nearly aborted, and the keel forms at its base a honey sac. This curious structure has led to the supposition that the flowers are visited by humming-birds. *Brugmansia Knightii* is another favourite in cultivation with inverted flowers that is said to be visited by humming-birds, but such instances are very uncommon.

A Beautiful Early Crocus.—In some sheltered spots the flowers of the charming *Crocus Sieberi* are already showing, and, given a few sunny days, will soon be fully open, and so reveal the beauty of the orange-coloured stigmata. This colour makes a fine contrast to the soft lilac hue of the petals, which, it must be admitted, are rather easily damaged by bad weather. However, it is a *Crocus* that we would not like to be without, coming as it does in the wake of the *Snowdrops* and *Winter Aconites*.

Improving Lawns.—Tennis lawns and golf putting greens that, from pressure of work, were not top-dressed in the autumn should now receive attention. If moss is present, scarify the ground with a sharp-toothed rake, give a good dressing of ground lime or powdered charcoal, and afterwards apply some sand and sifted soil, distributing it evenly over the surface with a broom or the back of a rake. It will, however, be too early to apply artificial manure; this had better be deferred till March.

The Winter Heliotrope.—*Petasites fragrans*, commonly known as *Winter Heliotrope*, although so often looked upon as a weed, is worthy of more notice than it sometimes receives. The scent is very pronounced, somewhat similar to the well-known *Cherry Pie* (*Heliotropium peruvianum*), and if grown in pots and placed in the greenhouse or sitting-room when in flower, very few plants that we are acquainted with afford so rich a perfume, although perhaps the peculiar Almond-like scent may not be agreeable to all. Although highly valued for the fragrance of its blossoms produced now, at what might be termed a dreary period of the year, precautions should be taken when introducing it into the flower border. A good plan is to enclose the roots in a large flower

pot or pan, and plunge this in the ground, otherwise the roots spread rapidly.

Alterations in the Rock Garden.—Any alterations intended to be made in this department should be accomplished as soon as possible, so that planting may take place before the season is too far advanced. When sharp frost is over, it may be found necessary to reduce some of the stronger-growing plants to make room for choicer subjects, such as hardy *Primulas*, which are not grown so much as one might expect, considering their hardy constitution. They will live through a severe winter, provided they have good drainage. Their habit of raising themselves above the surface of the soil renders it necessary to apply a top-dressing of good soil in the autumn.

The Cilician Winter Aconite.—This plant, *Eranthis cilicicus*, has but little to distinguish it from our older one, *E. hyemalis*, the ordinary *Winter Aconite*. Both flower very early, and both have yellow flowers surrounded with the pretty Elizabethan ruff of green, which increases their beauty so much. The flowers of *E. cilicicus* may be slightly larger and possibly more finely cut, though this serration varies in different lots, and the shade of green may be slightly deeper or more bronzy; but for all garden purposes there is little to choose between the two. A moist soil suits the *Winter Aconite*, and, though common, it is a flower we cannot well dispense with if we wish to have a glint of gold very early in the year.

Help for Aged and Infirm Gardeners.—On another page will be found a report of the annual election of pensioners on the funds of the Gardeners' Royal Benevolent Institution. We take this opportunity of appealing to our readers to subscribe to this admirable charitable Institution, which exists for the purpose of granting pensions to old or infirm gardeners, or the widows of gardeners. It is extremely sad to think that many thoroughly deserving persons cannot be relieved of unmerited distress, owing to the lack of funds. The Institution is conducted by a strong committee, the members of which are held in the highest esteem in the world of gardening, and as all expenses, which are really very low considering the amount of work done, are met by the interest on investments, every penny subscribed is used for actual relief. We therefore hope that our readers, in enjoying the many beautiful flowers in their gardens, will give more than a passing thought to these poor old people, many of whom in the past have contributed their quota of industry in bringing these flowers into being, and who, through no fault of their own, have fallen on evil times. The secretary is Mr. G. Ingram, 92, Victoria Street, Westminster, and he will be pleased to furnish anyone with full particulars concerning the work of the Institution.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Briquettes from Coal-dust.—Is it possible to concoct "home-made" briquettes (for burning on a coal fire, open or closed) from an accumulation of coal-dust? If so, what should be mixed with the coal, and what is the method for making and shaping the briquettes?—Clossy, *Hants.*

Mossy Saxifrages in Winter.—I can fully endorse all that is said about Mossy Saxifrages (issue January 10, page 17) and the dense carpet of vivid green in winter. In frosty weather, however, the contrast with the sombre hue of the surrounding rocks is even greater, as may be judged from the accompanying photograph, taken on January 24 last, when vegetation generally was clothed in a mantle of hoar-frost.—C. Q.

Primula pulverulenta Mrs. R. V. Berkeley.—I am grateful to Dr. Macwatt for having corrected my description of this Primula, which appeared in your issue of January 10, page 22. There can be no doubt that the variety figured is the same as Dr. Macwatt's, for both were obtained from the same source. As for the seeding of this variety, I have since learnt that so far it has not produced seed in this country, although it was originally raised from seed sent home by Messrs. James Veitch and Sons' collector from China.—A. D. M.

The Gold Mohur Tree.—In your issue of January 17 I note that Mr. T. Tillard has answered "G. D.'s" enquiry about the Gold Mohur Tree. Mr. Tillard is right in saying that it is a variety of Poinciana—it is Poinciana regia, of, I think, the Acacia family. It flourishes considerably in Lower Burma and the Straits Settlements. It grows beautifully in Maulmain, Tenasserim, where it was first known by the Burmese as "Yondawbyar," meaning "The Coming Back from Court Flower," as a tree had been planted near the Court House, and the young clerks used to stick a flower of it in their hair and take it home to their sweethearts or wives.—BURMA.

A Fine Plant of Euphorbia jacquiniæflora.—Some time back, when looking round an old garden in this North London district, I made note of a very good specimen of the above plant, which was growing in a border of a warm greenhouse. I was unable to gather any actual data as to its age, but it had evidently been there a good number of years. It was about three feet in height and rather more in width, while some of the stems were of considerable thickness, which fact would strengthen the idea of age. It has not been my good fortune to grow or see grown such an excellent plant as the foregoing. The usual practice, as is well known to plantmen, is to grow them in pots either singly or in threes, and, however well

done, the occasions are rare, I venture to affirm, when they approach anywhere near the above dimensions. Apparently the border method of growing this Euphorbia is most satisfactory, at least where large plants are valued, together with the possibility of their living several years. After once the cuttings are struck (a difficult matter at times), I do not think the secret of doing this plant well rests with the tremendous heat, as some growers advise, but rather with a well-drained and warm rooting medium and more air than is usually given.—C. T., *Highgate, N.*

Late-Flowering Roses.—The Rev. David R. Williamson writes us from Kirkmaiden Manse on January 24: "It may interest your Rose-

have only to add that Viscountess Folkestone, one of the most fragrant and fascinating of all Roses, and the beautiful Bouquet d'Or are also flowering still."

— So much has been written about late-blooming Roses that it may seem ridiculous to mention that on January 9, when visiting the nurseries of Messrs. Allwood Brothers, near Hayward's Heath, I found a batch of Roses in their garden blooming quite freely. Several hundred bushes in the open nursery were practically bare of leaf, but in the garden, sheltered by a tall hedge, the bushes were full of foliage, while really fine flowers of Richmond, Lady Ursula, Mrs. W. Christie Miller and many others were to be seen on every hand. On pointing out the value of all flowers at the present time, one of the men was told to cut the blooms, for many of the Richmonds were equal to those making 5s. per dozen in the market.—T. A. W.

Ranunculus Matthewsii and Varieties.—Readers of THE GARDEN, and especially lovers of rare alpine, owe a debt of gratitude to Mr. W. Wilcox of New Zealand for the photograph of that little-known plant R. Matthewsii, an illustration of which appeared on page 2 in the issue of January 3, and for bringing to the notice of the flower-loving public one of the finest sub-alpines of the Antipodes. To let his note and illustration pass unnoticed not only damps the ardour of the warmest enthusiast, but discourages him from sending further notes which might prove helpful and interesting. Writing in answer to a note of mine which appeared in THE GARDEN about three years ago, your esteemed correspondent "S. A." thought the species difficult to cultivate and establish in this country. But at the great International Show, 1912, Messrs. Backhouse of York seemed to have dominated those difficulties. As reported in THE GARDEN, May 25, 1912, page 256, we read that this enterprising firm had exhibited in their rock garden "the rarely

A WINTER SCENE IN THE ROCK GARDEN. MOSSY SAXIFRAGES COVERED WITH HOAR-FROST.

loving readers to learn that I have had several highly attractive varieties in flower in my garden within the past week. Among these were an abnormally tall plant of Margaret Dickson, which, after climbing through an exceptionally high Hawthorn hedge for fully five years, now blooms at least three times in the year at a height of not less than 21 feet. Another specimen of the same heroic and highly attractive Hybrid Perpetual (which should rather be regarded as a Hybrid Tea, as Lady Mary Fitzwilliam has imparted to it many of her best attributes), which is also at present in flower, overtops an Apple tree in the centre of the garden at an almost equally proud elevation. Its world-renowned raiser, Mr. Alexander Dickson of Newtownards, is naturally much gratified by its achievements in my garden. I

seen Ranunculus Lyalli (of which Matthewsii is a variety), with its handsome flowers of glistening white above the setting of glossy peltate leaves. This is perhaps one of the rarest plants in the exhibition, one to look for and admire." In THE GARDEN for July 30, 1910, an excellent illustration is given of R. Lyalli, from a photograph sent by a New Zealand reader, Mrs. Izard of Whanaka, which gives a good idea of the beauty of this plant growing in its native habitat. Mr. Wilcox informs me that he has still another rare thing in store, and is looking forward to it flowering this year. This is R. Lyalli variety Traversii, which he collected four years ago.—J. E. DAVIES, *The Gardens, Talygarn, Pontyclun, Glamorganshire.*

A NEW SCABIOUS:

Scabiosa caucasica magnifica.

Eceremocarpus scaber.—How is it that this handsome climbing plant is to a great extent neglected? True, it is not, strictly speaking, hardy, but one sometimes finds plants of this so-called half-hardy perennial which have become thoroughly established and produce an annual display of their trumpet-shaped, orange flowers. The writer last autumn saw a splendid example of this plant in Essex. This particular specimen receives no protection during the winter, and has been growing for several years in its present position. Plants can be raised from seed, but if sown in the ordinary way, viz., covered over with soil, the results are anything but satisfactory. Seed which falls to the ground will often germinate freely. This fact gives one the correct method to adopt when sowing. Seed sown in shallow trays containing a thin layer of moist soil and not covered will almost invariably germinate. The trays may be placed in a frame or cold house and given a shady position. Do not allow the soil to become dry.—C. R., *Saffron Walden*.

A Good Plant for a North or East Wall.—White-flowering plants suitable for planting against walls having a north or eastern aspect are not too plentiful. There are several species of Clematis which thrive in these positions, also Spiræas. The subject of this note, *Deutzia crenata*, or, as it is sometimes called, *D. scabra*, is not so often seen as it should be. Although often met with in shrubberies, where it is frequently a sadly neglected plant, its qualities as a climber are not fully appreciated. The principal reason is that the proper method of pruning is seldom followed. This is one of the many *Deutzias* which require severe pruning immediately after flowering. The flowers are produced on the young shoots of the previous season's growth, and the stronger these shoots are, the better the flowers. Young growths 5 feet or 6 feet in length are produced by this treatment. These should be secured to the wall about eight inches apart. A good loamy soil suits the plant, and moisture is essential during the season of growth.—COLIN RUSE, *Sulhamstead*.

A New Race of Winter or Early Flowering Sweet Peas.—More than eighteen months ago I was told by Mr. Arthur Yates of Sydney, Australia, that a very precocious sport had recently appeared there among some ordinary Spencers. The seed had been saved, and a wonderfully early flowering strain had resulted. This is known in Australia as the Yarrowa Spencer, and has been a decided acquisition in such warm climates as that of Sydney, for if seed be sown in late summer or early autumn, the plants will begin to bloom in two months from the time of sowing, and continue in flower for some two or three months longer; in fact, until the hot weather begins. This strain has now been crossed with the older winter-flowering varieties, with the result that a large and vigorous race has been obtained, which is further distinguished by well-formed blooms of much substance. The name "Concord Hybrids" has been given to it, and it is said by the raiser to be superior to the Algerian one of Arkwright, the American of Zvolanek, or the British of Engelmann. I am going to try these Australian seeds this spring, and I hope to send an account of them later on in the year. It seems to me that a public trial of these various early flowering strains that are now before the public would be most useful. Why should not the Royal Horticultural Society be asked to find room for a small representative collection of each of them, and grow some in pots under glass and some in the open? I find these

early Sweet Peas so very useful, and I would like to know which is the best.—JOSEPH JACOB.

Ceanothus Gloire de Versailles as a Pot Plant.—Having given this shrub a trial as a pot plant, I have been agreeably surprised to find how readily it responds to such treatment. One is so accustomed to see it making a glorious display on a wall, herbaceous border, or in a shrubbery, that it is rather difficult to picture so much at home in a pot. To those, however, who have not grown it in this way I would suggest doing so, for the result will afford ample compensation. A strong point in favour of this treatment is the advantage of being able to hasten or retard the flowering period. Quite nice bushy plants may be obtained in 6-inch or 7-inch pots. While any kind of forcing should be avoided, the *Ceanothus* may safely be placed in a warm greenhouse to hasten its growth a little in early spring, a light, airy position being chosen. In order to be retarded, the plants should be plunged in a bed of ashes under a north wall, and pruning delayed as long as possible. After the flowering period an outside position in full sunlight ripens the wood and ensures another successful display the following season. The plants should be wintered outside, with the pots plunged to protect them from frost. When pruned, the young wood should be cut hard back to one or two good "eyes."—H. TURNER, *Serlby Gardens, Bawtry*.

An Interesting Shrub.—Though by no means a brightly coloured flowering shrub, the Bladder Senna (*Colutea arborescens*) has its own particular beauty, which is quite sufficient to justify its inclusion in even a limited collection of shrubs. The *Coluteas* belong to the Order Leguminosæ, and are easily grown shrubs, thriving in poor soil and in exposed situations. *C. arborescens* is said to be one of the few plants that grow on or near the crater of Mount Vesuvius. The flowers are borne in great profusion in short sprays, and are yellow in colour. These are followed by the seeds, which invariably set with great freedom, and are contained in highly inflated pods. These latter are the chief attraction, and a good-sized shrub covered with these peculiar-looking pods always attracts attention. There is a variety, *media*, which is even more prolific than *arborescens* and not quite so large in the size of the bush. The colour of the flowers is also different, being more of an orange shade. This variety was very fine last autumn in Mr. Brough's interesting garden at Ochilview, near Perth, where it was greatly admired by numerous visitors. Among the many choice shrubs grown there it was the outstanding feature during August and September. *Coluteas* are easily increased either by seeds or cuttings, the latter taken off with a heel and inserted in sandy soil in autumn either in a cold frame or in a sheltered corner outside.—W. L., *South Ayrshire*.

FORTHCOMING EVENTS.

February 9.—United Horticultural Benefit and Provident Society's Committee Meeting.

ROSE-GROWING IN TOWN GARDENS.

HYBRID PERPETUALS, although among the hardiest Roses, are by no means best for town gardens. For the most part they are more fastidious as regards soil than the Hybrid Teas, and are only really satisfactory where the staple is of a heavy nature. All are more or less addicted to mildew, and, speaking generally, they are strong growers which do not give results in proportion to the space they occupy. However, we must still look to the Hybrid Perpetuals for some of the best dark reds, and although they are mostly inferior to the Hybrid Teas in regard to shape and freedom of flowering, almost all are very sweetly scented.

The Best Hybrid Perpetuals.—The two that no Rose-grower can afford to be without are Frau Karl Druschki and Hugh Dickson. Both are known and grown everywhere, and there can be hardly a Rose garden in which they find no place. If the garden be very small—and unfortunately there are many such in towns—it is best to limit the choice in Hybrid Perpetuals to these two varieties, relying on the Hybrid Teas for the rest. In this case they can be grown as standards on the lawn, for which both are eminently suitable, and they will make good companion trees. The red and white form a very effective contrast, and this arrangement has the advantage of separating them from the Hybrid Tea and Tea Roses. Both are rather difficult to accommodate as dwarfs, on account of their unwillingness to behave as such. Frau Karl Druschki has an especially awkward habit of breaking with tremendous vigour from the topmost eye, which must be fully taken into consideration at pruning-time, or plants become unshapely. Both are suitable for pegging down.

Those with sufficient room to devote one or more beds to this section will find a number do quite well in towns where the soil is suitable. Ulrich Brunner is a fine, sturdy grower, free-flowering and very sweetly scented, though not always satisfactory in the quality of the blooms it gives, and its very light green foliage seems to have an extra attraction for all insect pests. Mrs. John Laing is another fragrant and good all-round variety, though it seems hardly necessary to go to the Hybrid Perpetuals for pink Roses. Gloire de Chedane Guinoisseau is a promising variety of fine shape and colour that seems likely to become a recognised town Rose. Captain Hayward is a fine Rose of a dazzling shade and free-flowering, but not good in a hot season, and even more insistent than most Hybrid Perpetuals in demanding a clay soil. Those who would have dark crimson kinds should include in their selection Fisher Holmes, Charles Lefebvre and Commandant Felix Faure. In the case of many of the old Hybrid Perpetuals, half a century or more of artificial propagation seems to have robbed them of some of their original characteristics. Of Prince Camille de Rohan, what is practically a non-flowering strain seems to be pretty widely distributed. Marie Baumann is another which seems to have deteriorated, and many nurserymen are giving it up. Margaret Dickson and Mrs. Sharman Crawford should not be grown in town gardens, both being too prone to mildew, while Horace Vernet is of little use except on the maiden plants.

Rambling Roses and their use in town gardens will be dealt with on February 14. P. L. GODDARD.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER POMPONS (POLYANTHAS).

FROM climbers and semi-climbers one passes to the other extreme, namely, the Pompon or Miniature Roses; and one would like to emphasise the fact that a very great deal of pleasure is missed by the Rose-grower who omits to have a fair selection of these delightful Roses in his garden. One of the first as a class to flower—by reason of the fact that no pruning is required, only a removal of the flower-stems of the previous season; these carry no dormant buds, but are bare of all possibility of further growth—they go on flowering, so much so that if a Rose is ever to be found on a plant in every month in the twelve, it is on these Pompons that I should expect to find it. At the present time (January 20) Mme. E. A. Nolté, one of the stronger-growing varieties, is carrying flowers and buds in profusion, and that same bush had flowers on it in April last year, so that is ten months out of the twelve. Some of them, of course, drop their foliage, and with the foliage goes the flower; but others seem to retain it until the new growth literally pushes off the old. There have been quite a number of additions to this class during recent years, but I have not attempted to keep pace with them in my own garden, only getting the best of those I have seen growing elsewhere. Among those I have seen in this way are the following:

Backfisch (Peter Lambert, 1910).—This is rather a cruel sort of name for a pretty Rose; pink blossom, not very large, but of distinctly good shape. No doubt there is a reason for the label, but these things ought to be translated for us. The plant is free-flowering.

Cyclope (Dubreuil, 1910).—This was described as an improved Jessie; but I prefer Jessie. It is a dark crimson, with a distinct white stripe, and is possibly as free-flowering.

Daphne (Rev. J. H. Pemberton, 1913).—This is, I see, classed with the Pompons, but is really a Hybrid Musk, one of those Roses possibly that it was hoped would climb; but it has refused to do so. At any rate, it is perpetual flowering, and is vigorous for this class. Semi-double, pretty rose pink flowers, fading to flesh.

Erna Teschendorff (Teschendorff, 1911).—Another "improved Jessie," and this time with possibly somewhat more title to that distinction. It is a good dark crimson that does not fade; said to be a sport from Mme. Norbert Levavasseur. Let us hope it will never revert back to its parent. What an appalling colour Mme. Norbert Levavasseur can be, and generally is!

Ellen Poulsen (Poulsen, 1912).—A good deep pink, nicely scented. All these Roses are free-flowering and perpetual, so I shall leave out these two remarks in dealing with the remainder. The flowers are rather larger than the usual run of Pompons.

George Elger (E. Turbat and Co., 1912).—This is quite one of the best of these new introductions:

a good bright, clear yellow, deeper, of course, in the bud. Flowers medium size, and making a nice-shaped plant.

Jenny Soupert (Soupert et Notting, 1912).—This is a good-shaped white, flushed pink in the early stages. Nice large clusters of flowers; likely to be useful.

Jessie (Merryweather, 1909).—This well-known Pompon is only mentioned here to draw attention to the fact that it makes a really excellent half-

Orleans Rose (Levavasseur, 1910).—A deeper coloured Mrs. Cutbush, and by some said to be preferred of the two, as it is, if anything, the freer flowering, especially in the autumn. It flowered here right up to Christmas. It is quite good.

Pompon de Lyon (Dubreuil, 1913).—Another deep pink, but distinct enough. Not so strong a grower as some. One would call it medium for this class; that is, about 12 inches or 15 inches.

Queen of the Musks (Paul and Son, 1912).—This is a delightful Rose; Hybrid Musk I suppose we should call it. Very free, and making an excellent bedding Rose. Flesh white flowers, with deeper-coloured buds. Recommended.

Yvonne Rabier (E. Turbat and Co., 1911).—The companion to Maman Turbat at the Chelsea International Exhibition. This is a fine white; flowers large and produced in beautiful panicles. A most effective bedding Rose. Recommended.

Six good varieties of the older sorts in distinct colours would be found in the following: Leonie Lamesch (very tall), Mme. E. A. Nolté, Philippine Lambert, Perle d'Or, Cecile Brunner and Eugénie Lamesch (very dwarf).

Southampton. HERBERT E. MOLYNEUX.

FRASERA SPECIOSA, A LITTLE-KNOWN PLANT WITH CREAMY-WHITE FLOWERS.

standard, and, so used, has a quaint effect as isolated or dot plants.

Maman Turbat (E. Turbat and Co., 1911).—First seen at the Chelsea International Exhibition, where it was much admired. As seen out of doors, it is even finer. It makes fine growth, and produces its flowers in very large trusses. Colour, pleasing China Rose. Recommended.

CANKER IN FRUIT TREES.

[In Answer to a Correspondent.]

OF all the troubles of fruit-growers, canker is one of the most general and the most easily recognised. Most of us are too familiar with the large, unsightly gaps it makes in the bark of Apple trees, gradually spreading round the branch until it has completely girdled it and the branch dies. Canker has been attributed to a very large number of causes, and there are undoubtedly several different forms on Apples in various parts of the world, and probably more than one in this country, but the commonest is that associated with the fungus *Nectria ditissima*, the bright red fruits of which are being produced now on canker spots on the affected trees. Like many other disease-producing fungi, this can only attack trees through open wounds. The spores applied to the healthy, unwounded bark have no power of penetrating it; but should they, in early spring or in summer, when the spores are liberated in myriads, be carried by wind or insects on to an open wound, they will germinate, and in all probability make their way into the cambium and quickly destroy it. Thenceforth there is a constant struggle between the affected

plant and the fungus for supremacy. The plant during its more active periods will strive, by making a wound-healing callus, to cover up the wound, and may, if it be in thoroughly good health, succeed in doing so and in getting the better of the fungus; but generally, as soon as growth is checked by seasonal changes, the fungus grows ahead and destroys the tissues newly made. This kind of thing will go on year after year,

sometimes for many years if the diseased branch be a large one, the wound in the bark becoming more and more open, and allowing bacteria and so on to reach and cause the decay of the wood.

One of the first effects of the attack—the destruction of the bark over some considerable area—causes the flow of food made in the foliage down the stem to be interfered with. A greater quantity of food is thus kept in the stem above the wound, and, at the same time, there is a lessening of the water sent up the wood, since the death of the cambium has caused a cessation in its formation. This increase of stored food and decrease in water supply has the usual result of increasing fruitfulness, though the fruits produced will probably remain small. The last state quickly comes, however, growth gradually or rapidly ceases, and death supervenes.

Two things, thus, are necessary for the spread of the disease—the fungus, and the wound by which it may enter. It is impossible to exterminate the fungus, for, although great care would destroy it in orchards, there still remain Crab Apples, and, in addition, several other native trees are liable to attack. Wounds difficult to heal can be avoided to a large extent, however, by taking care that all cuts made are clean and large ones; after smoothing over with a knife, protect by painting with lead paint or tar (not smearing with earth, as is so often done). Wounds made by insects, frost cracks, dead shoots breaking off, careless climbing about in trees, gunshots, and the like are also a menace. Of insects, none is worse than the woolly aphis or American blight. The soft tissue produced as a result of its attack is very liable to act as a nursery for the fungus while it is young, and from this spot it spreads and does serious damage. Frost cracks and dead shoots resulting from frost in spring are always more common in wet and low-lying localities than in places where there is a free circulation of air and thorough soil drainage. The bottom of a valley is one of the worst spots for late frosts as a rule; higher up the slope the trees are far less liable to suffer. These frost wounds are mostly at the base of a bud, or in the angle between stem and branch. The other causes of wounds can be avoided with care, and, where they occur, every care should be taken to protect the wounds made.

Certain varieties are more subject to canker than others, probably because they are more liable to wounding. Ribston Pippin, Cox's Orange Pippin, and Wellington (or Dumelow's Seedling) are notoriously liable to canker, and where heavy soil or places liable to sharp late frosts have to be dealt with, it is wiser to select the hardiest varieties of Apple.

Cutting out and burning the diseased patches is the only method of dealing with the disease when once the tree is attacked, and, at the same time, care should be taken to paint over wounds thus made. The knife used should be dipped in carbolic acid or in methylated spirit after each cut is made.

It should be remembered that the bright red fruits already referred to are not the only source of infection. The fungus produces another type

of spore by which it is spread, this time taking the form of whitish patches on the canker spots and occurring during the warmer parts of the year, so that immediate attention to any wound is best.

SCIENTIST.

FRASERA SPECIOSA.

THE little-known genus *Frasera* contains about seven species of North-West American hardy perennials belonging to the Natural Order Gentianaceæ. One of the most showy species is *F. speciosa*, which sends up a straight and strong flower-spike from 3 feet to 4 feet in height. The general appearance of this plant resembles that of a *Veratrum* or False Hellebore, which, however, belongs to quite another Natural Order, viz., Liliaceæ. The flowers of *F. speciosa* are creamy white, and are borne in June and July. It thrives in a fairly moist situation, and forms a suitable subject for planting in a low bay in the rock garden.

plantation—this Saxifrage grows in such abundance that its deep green leaves and rosy purple (ranging to pale pink) flowers can be seen from a considerable distance. It seems hardly credible that the plant could find sufficient nourishment in such a waste of stone to thrive so luxuriantly; but no doubt the constant decay of the older leaves provides some amount of humus, and the patches of growth are sure to arrest any finer particles which may come down the mountain-side.

REGINALD A. MALBY.

ORCHID NOTES.

THE CALANTHES.

THESE are terrestrial Orchids which may be divided into two sections—the evergreen and deciduous—and it is with the latter that I shall deal. They are very popular plants, and are largely grown in gardens where there is no

SAXIFRAGA OPPOSITIFOLIA GROWING AMONG STONES ON A MOUNTAIN SIDE.

The genus *Frasera* is named after John Fraser (1750–1811), a collector of North American plants.

SAXIFRAGA OPPOSITIFOLIA IN ITS NATIVE HABITAT.

THIS Saxifrage, a large scale illustration of which appeared in THE GARDEN of November 30, 1912, has its principal habitat among the rugged rock-falls of the higher passes, where its minute growths make vast cascades of verdure, mantling the rocky ground. The accompanying illustration shows forcibly the kind of position in which it makes its home. Here, forming an enormous buttress against the steep western face of the Schwarzhorn, in the Valais, lie the shattered remnants of that portion of the mountain upon which the elements have made such an onslaught. Many of these blocks, which lie about in all directions, weigh several tons, and in the interstices of these huge lumps—probably where some small amount of wind-blown detritus had accumulated to start the

attempt made to cultivate other Orchids. This can be easily understood when we take into consideration their free-flowering qualities, and the fact that the long spikes are produced from December till March.

Repotting.—After the flower-stems are removed, the pseudo-bulbs take a short rest in a temperature of 50° to 55° Fahr., and when growth and root action commence, the repotting must be done. Some growers place one bulb in a pot, but where the bulbs are plentiful several may be included, so that a nice specimen that will come in very useful for decoration in the dwelling-house is secured. The largest bulbs may be planted singly in 5-inch pots, and about four of the smaller ones in a 7-inch or 8-inch pan. Each receptacle should have one-fourth of its depth filled with drainage, over which is laid a thin layer of fibrous loam. If not already done, the bulbs must have all the old soil shaken away, and the roots cut back to an inch or so of their base, the object being to leave a little tuft

to keep the bulbs firm in the fresh compost. This consists of the best fibrous loam one-half, peat one-fourth, the other part being made up of sphagnum moss, small crocks or charcoal, and a little manure from the old spent Mushroom-bed or a sprinkling of bone-meal. The whole should be broken up into pieces about the size of a Walnut, and when thoroughly mixed it will be ready for use. Press the soil fairly firm, and when the operation is completed, the surface ought to be just below the rim, as *Calanthes* enjoy plenty of water when thoroughly established.

Subsequent Treatment.—A light position in the plant stove, Cucumber-house or warm Orchid-house should be selected, and water ought not to be given frequently until the roots take possession of the compost. As growth advances and the new bulb forms, they must never be dry at the base till after the flowering period. A moist atmosphere must be maintained, and a little top and bottom

kind is required, *Regnieri* should be chosen; it blooms at a time when all fear of fog is passed.

T. W. BRISCOE

TWO INTERESTING SHRUBS.

THE WINTER SWEET.

(*CHIMONANTHUS FRAGRANS*.)

IT is no small wonder that the fragrant flowers of the Winter Sweet are so much appreciated, for they are borne in the depth of winter, however bleak and cold it may be. Moreover, the sprays are so useful for cutting, the flowers lasting for weeks in a room and yielding their precious fragrance the whole time. This shrub was introduced from Japan nearly a century and a-half ago, and it is bound to remain

at home on a wall of any aspect, at least in Southern gardens. A deep, rich sandy soil suits it best, and it should be kept trained neatly to the wall or building against which it is planted.

A BEAUTIFUL ROCK ROSE.

CISTUS CORBARIENSIS

ALTHOUGH not often cultivated, this is unquestionably one of the most delightful of all the Rock Roses. In June it is literally smothered with small white, satin-like flowers that resemble single Roses. It is of low-spreading habit, not exceeding 2 feet in height. Like other Rock Roses, it is well adapted for a warm bank or a sunny position in the rock garden, and it seems to show preference for a stony soil. *C. corbariensis* is sometimes regarded as a variety of *C. salvifolius*, but it is probably a hybrid between that species and *C. populifolius*.

In very hard winters it is not unusual for some of the Rock Roses to be severely damaged, or even killed outright, by frost. This, however, may be guarded against by covering up the compact shrubs either with dry litter or mats. One of the hardiest species is *C. laurifolius*, which does quite well even in Scottish gardens, while *C. purpureus* and *C. ladaniferus* are two other beautiful species that as a rule withstand frosts satisfactorily. Like the Sun Roses (*Helianthemums*), to which they are related, the Rock Roses are delightful subjects for growing on sunny banks or in positions facing south in the rock garden.

CISTUS CORBARIENSIS, A BEAUTIFUL ROCK ROSE SUITABLE FOR CLOTHING A WARM BANK.

THE CAUCASIAN SCABIOUS AND ITS VARIETIES.

COLOURED PLATE 1486.

IF I were asked to give the names of a dozen first-class herbaceous plants, I should certainly include the Caucasian Scabious, despite the knowledge that there are those who, gardening with hardy plants alone, say they are unable to cultivate it. That condition of things is, I fear, due to the belief that it is only necessary to plant it in ordinary

ventilation be given during hot weather. *Calanthes* do not require so much shade as the majority of Orchids, but some slight protection from the strong rays of the sun is necessary during the hottest part of the year. When the bulbs are near completion, the foliage will begin to decay at the tips, and the spikes appear near the bottom of the pseudo-bulb. To keep the plants tidy, the leaves may be trimmed with a pair of scissors, but this is not necessary, only for the sake of appearance.

The Best *Calanthes*.—Hybrids play an important part, and the most popular of all is the rosy pink *C. Veitchii*. Then we have the pure white *Harrisii*, *Oakwood Ruby*, *Baron Schröder* and others, while the principal species are *rubens*, *rosea*, and *vestita* with its numerous varieties, the best being *luteo-oculata*, *Regnieri*, *rubro-oculata* and *Turneri*. Where a late-flowering

a favourite, for those who have once had it in their gardens look for the fragrant flowers in midwinter as eagerly as others look for the opening of the first Snowdrop in spring. Occasionally one hears of complaints about the paucity of flowers. This may be due to very youthful plants or improper pruning. Obviously it would be a mistake to prune in autumn, for this would mean the removal of flowering wood. The correct time to prune is after flowering, and just as the young leaves are about to develop. The flowering wood may then be cut away, or at least very much reduced, to make room for new growth, the flowers being borne on the wood made the previous season.

The variety *grandiflora* is an improvement on the species, the flowers being larger and more open, but it is scarcely as hardy. It does well on a south or west wall, whereas the species appears quite

garden soils and expect the finest results. That is a mistake at the outset. As a matter of fact, this particular species would appear to abhor heavy retentive soils, though quite at home in some of the stronger loams where these are of a sandy nature and well drained. At the same time, an even greater measure of success follows its cultivation in light and warm soils, and it offers no objection to those largely composed of vegetable matter, or others of a peaty nature. In a word, therefore, the plant may be said to flourish in light, well-drained soils in preference to all others. If such as these are at planting-time enriched by the addition of a good layer of cow-manure a few inches below the base of the plants, so much the better.

In such circumstances the seedling plant will make fine tufts in the course of a season, and in turn yield in the following year a rich harvest

of flowers of which any hardy plant grower would feel justly proud. In point of colour beauty and refinement the Caucasian Scabious is one of the indispensables, one that no good garden should be without; hence it is suggested that the soil be made to suit the plant. The delicate lavender blue of its flowers is quite a rarity in the garden at any season, and few are more highly prized in the cut state. The florist-decorator thinks well of it, and it is alike as valuable to the exhibitor of hardy flowers as for the decoration of the border at home. So much, then, in justification of my opening statement, and a plant possessing the good attributes named merits not merely good cultivation, but specialisation, should occasion

Raising from Seeds.—Apart from the important question of soil, that of raising the plant periodically from seeds merits close attention, for more than one reason. On light and warm soils this handsome Scabious is usually a good perennial. On heavy soils it is not so. Then, again, because of its abundant and profuse flowering, the stools become exhausted; hence the need for replacing them with others of a more youthful and vigorous nature. Happily, seeds are abundant and cheap, and, vegetating quickly and with comparative certainty, afford the readiest means of propagation to amateur and professional alike. The seeds should be sown preferably during the autumn or winter months, so that, vegetating in the earliest days of spring, there is still a full season ahead for the plants to make good growth. These would be best in a cold frame. Seeds sown in February or later should be given greenhouse treatment, a temperature of about 50° being ample. In either case the seedlings should be potted off singly when large enough to handle and grown without a check from the start, so as to be ready for their permanent quarters in the open ground early in May.

Varieties.—Though variations naturally occur when raising plants from seeds, the species has not been prolific of good or distinct forms, though such names as *superba*, *atrocærulea*, *perfecta* and others have been catalogued. A good white variety received an award of merit so long ago as 1895, an honour never granted to the typical kind. The white is not pure, however, and there is abundant room for another of more glistening purity. The most recent addition—it is an acquisition as well as a novelty—is that depicted in the coloured plate presented with this issue. This originated with Messrs. James Cocker and Sons, Aberdeen, and when exhibited by them in August last as *Scabiosa caucasica magnifica* (Cocker's Variety) gained an award of merit from the Royal Horticultural Society. It is the finest I have seen, the flowers larger and of a

deeper lavender blue than the original. The stock at present is limited, and as in common with such plants the seedlings do not come absolutely true, propagation has to be effected by division—a rather slow method.

E. H. JENKINS.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

Arrangement of Plants.—I wonder if there ever has been a border so perfectly arranged as to give complete satisfaction! The spotty

perfection, it is best to assure ourselves that in the production of herbaceous borders it is a thing unattainable. Were we to hit on an arrangement perfect in every respect, there are so many vicissitudes in front, from the young gardener's clumsy boot to the changeableness of our climate, that we can never hope to travel an undeviating road to success. Personally, I do not like any of the styles here noted. Nor do I care to stereotype any arrangement, but, on the contrary, like to vary the planting and, to some extent, the plants every year. It is true that the same flowers never tire the lover of flowers; but fashion must be consulted, and fashion is largely a gradation of changes. At the same time, I deprecate copying the planting of herbaceous borders, so largely the custom of to-day. No one can have a fresh garden whose schemes are the outcome of what has already been produced in other gardens, and it is to be preferred to retain the individuality of one's own garden, though at the expense of perhaps a short-lived brilliance, rather than have it a bad second to another. The person who thinks out schemes for himself is the one who sooner or later will be among the copied.

In Even a Narrow Border it is not essential to have comparative uniformity of height and evenness of slope. In a wide border it is important that these should not occur. Not only should the best plants be selected, but they should also be arranged so as to provide the best effects they are capable of giving. Thus we would mass certain plants, *e.g.*, *Rudbeckia speciosa*, *Phloxes*, *Eupatorium Fraseri*, *Pentstemon Southgate Gem* and others, *Polygonum affine* and certain of the *Asters*. Some we would mass and also employ singly or in close clumps. Such are *Hollyhocks*, *Liliums tigrinum*, *candidum*, *Martagon*, &c., *Gladioli*, *Aconitum autumnale*, *A. Wilsonii*, *Montbretias* and *Anemone japonica*, and there are a number which perhaps always should be graded singly—*Agapanthus umbellatus*, *Statice latifolia*, *Eryngiums* generally, *Francoa ramosa*, *Astilbes* and *Delphiniums*. Very important, too, are the parts of the border to which the various plants are

A SPRAY OF THE WINTER SWEET (*CHIMONANTHUS FRAGRANS GRANDIFLORA*), A HARDY SHRUB THAT FLOWERS IN MIDWINTER.

border, consisting of single plants disposed according to relative heights and colour; the triplet border, in which all, or nearly all, of the plants are arranged in threes; the chess border, with its divisions severely four-sided, with one kind of plant in each division; and the higgledy-piggledy one so prominent in published schemes of planting, with its impossible corners protruding into other equally impossible divisions, the prevailing objective being a striking dissimilarity of form and filled with plants as dissimilar as possible. Each and every one of these has its faults. And, really, though we may struggle to attain

apportioned. A handsome-habited plant should never, or hardly ever, be put where any part of it is hidden by another and less attractive plant. Hence in the front of the border should be found *Liliums*, *Carnations*, *Agapanthus* and such like *Hollyhocks*, as a rule, look best against a background, but care must be taken that the plants in front are not so tall as to obscure the charm of their individuality. *Galtonia candicans* is usually best placed behind plants tall enough to cover the foliage, which towards autumn becomes unsightly, the spikes only being seen. To me it is a serious drawback to gloriously coloured

arrangements that this important feature of form is so little, if at all, considered, the mere general height of plants being enough to decide what part of the border they shall occupy. Those who may cherish fears as to the general effect of a border not by any means homogeneous in height may dismiss them, because a border fairly apportioned with tall plants towards the back gives quite as good an effect, even though broken in several places by dwarfier plants, as one in which a similarity of height is maintained throughout. And that border affords great scope for particular effects. Thus there may be a bold mass of Hollyhocks well to the back, on one side supported with tall plants, while, on the other, groupings of low-growing plants from front to back afford a clear view of these stately flowers, and there is the added interest of variety in height and form to the good. The advantage of

A Wide Border is chiefly on account of the variety in arrangement of this kind, of which there is practically no end, because, reverting to the above instance, there may be an assortment of plants of various height, such as Campanula

decline to break away from hard lines and equi-distances, and every new hand has to be carefully broken in before the slightly natural way of arranging is acquired. It is usually along the front edge that the outcome of the mathematically minded planter is most evidenced, though the varying by a few inches makes all the difference. Another evil to be avoided in planting is the setting of front plants too far

there is no occasion to be so particular. To conclude this instalment, it may be noted that many

Early Flowering Bulbous Plants besides the well-known Scillas, Winter Aconites, Iris reticulata, &c., which grow through low carpets of vegetation, may be arranged all over the borders without being very particular whether or no they may be under some deciduous fibrous-rooted plant. Tulips are rather diffident of so close relations, but Narcissi, Fritillarias and English Irises do not mind a bit. In like manner Colchicums grow through other plants in autumn, and even the fragile-looking Crocuses, of which the common *C. speciosus* is perhaps the most engaging, do likewise. Individual taste must, of course, be considered in these, and, indeed, in all arrangements.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

(To be concluded.)

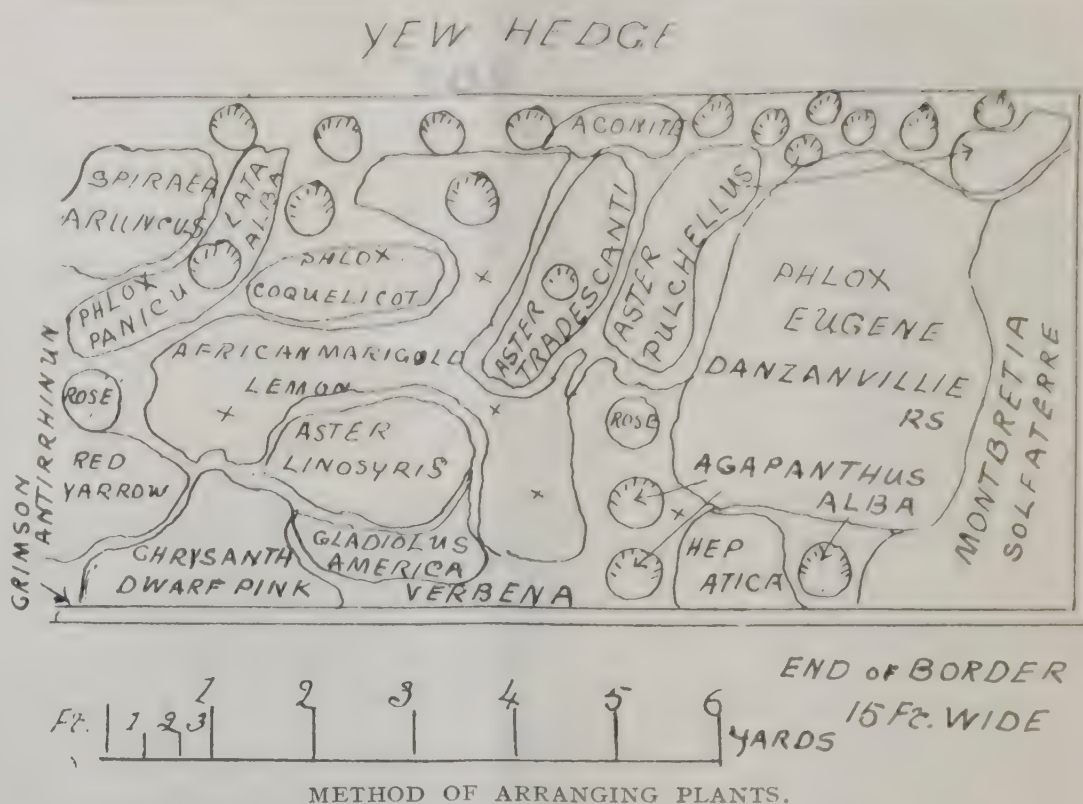

EDGE

AN EFFECTIVE WAY TO GROUP GLADIOLI, USING A CARPETING PLANT TO COVER BARE SPACES.

pyramidalis widely spaced, with dwarfier plants carpeting the ground. The illustration shows how to arrange Gladioli near the edge or front of a border with carpeting vegetation among them, such as Viola, Cornflower, or other suitable plant. Nor need there be too close adherence to the well-trod path of clumps of one species or variety of plants, a very nice by-path to loiter in occasionally being a mixed planting in carefully selected parts. It is perfectly wonderful, notwithstanding the many well-considered notes we have all read on colour grouping—good, bad, and indifferent—how plants themselves possessed of very inappropriate colours yet combine to give a happy whole. One of my own

Colour Combinations of the past year commenced with sulphur Montbretia and lilac Phlox, and passed on to a broad groundwork of Verbena, dwarf pink Chrysanthemum, lemon African Marigold, with taller plants dotted among them of Gladiolus America, Francoa ramosa, Phlox paniculata alba, P. Coquelicot, a few Asters and single Hollyhocks, and in front Agapanthus, white and blue. Here in the space of a few yards run is quite a constellation of floral stars, ranged apart from all the rest of the border, though forming at the same time an integral part of it. One of the most difficult things in the arrangement of plants is the planting. Workmen invariably

back. Whatever the edging to the border may be, the front plant should touch it. This, of course, with some things entails the pruning of encroaching shoots, &c.; but that is infinitely to be preferred to the bare and ugly soil that is the concomitant of a space left between the verge and the plants. Similarly, when a very tall plant is arranged behind a dwarf one, the former should be planted so that the two touch, and it is always a good rule in planting to set close those parts that would appear bare, though further back and unexposed to view

METHOD OF ARRANGING PLANTS.

The circles are pink and cream Hollyhocks, and the crosses Francoa ramosa.

GARDENING FOR BEGINNERS.

TREES AND SHRUBS FOR WIND SCREENS.

SHELTER in a garden is one of the secrets of success with many plants. Almost the first thing to do when making a garden in a windy or exposed place is to plant trees and shrubs to shelter it.

The best evergreen tree for bleak positions is the Austrian Pine (*Pinus Laricio austriaca*). To make a screen at once, plant 6 feet apart now, and then, when the trees touch, every alternate one must be cut out, leaving them 12 feet apart. Sometimes it is necessary to plant two or three rows. These may be all Austrian Pines; a fast-growing Poplar may be used, or Spruce and Larch. The Poplar is one of the quickest-growing and one of the most valuable screen trees, thriving well in the smoky atmosphere of our towns and suburbs.

The Canadian Poplar (*Populus canadensis*) is very fast-growing, but, being rather spreading in habit, can only be planted where ample space exists, though it will stand a little pruning. When a screen is required quickly, and one which will not shade the surrounding ground too much with its branches, there is nothing to equal one of the fastigate growing Poplars, *Populus alba pyramidalis* (*P. bolleana*) or the Lombardy Poplar (*P. nigra pyramidalis*), the former for preference. The illustration depicts a row of *P. bolleana* planted three years ago as a screen. The average height of the trees was then 8 feet. With one or two exceptions they are now 18 feet to 20 feet high, a good illustration of the rapid growth of this attractive and desirable tree. It is readily propagated from cuttings; those from which the trees in the accompanying illustration were grown were inserted six years ago last November. The distance apart for planting varies; 10 feet from tree to tree is a suitable distance, but an immediate effect may be secured by planting at half this distance, this amounting at once to practically a hedge. The Poplar is one of the easiest trees to transplant successfully; trees 10 feet or 12 feet high move with seldom a failure. The Aucuba, Laurel, *Berberis stenophylla* and *B. Darwinii* are useful evergreen shrubs to plant for shelter. Equal to these, or even better when the soil is suitable, is the common purple *Rhododendron* (*R. ponticum*). Screens of trees in

Town and Suburban Gardens are very valuable. One of the drawbacks and evils of building houses so closely is that the gardens are so much overlooked, making secluded nooks few and far between. This robs a garden of half of its pleasure. In some gardens old trees were left standing when the houses were built; in others, young trees have grown up since. One almost invariably finds the shade and shelter of trees very much appreciated and valued by the owners. Sometimes there is one disadvantage, and that is, when the tree or trees are in such a position, while they seclude portions of the garden from the surrounding houses, they also render a part of it useless for flowers. When planting trees, especially in small gardens, this point must be considered. For this reason one or other of the fastigate Poplars should receive consideration, as while they form a splendid screen, only a comparatively small light space is occupied by them. As already stated, they grow quickly,

and will thrive in almost any kind of soil, and in an atmosphere that would be fatal to many kinds of evergreen trees.

A. O.

THE CULTIVATION OF FIGS.

THE Fig as a tree is easily grown. In many instances, however, the inexperienced cultivator fails to secure a crop of fruits on the trees. Although very small trees usually possess many roots, a fair proportion being fibrous, such specimens will not mature fruit until the new soil has become thoroughly permeated with roots, and, moreover, it is essential to success that the rooting medium be a very firm one.

Unlimited rooting space means much growth and few fruits. Amateurs and others who possess

done while the fruits are swelling. Admit air freely in fine weather.

Trees in the Open Air.—Confine the roots to a small space—in a brick pit 18 inches wide, 15 inches deep and 3 feet long. This space will suffice for a tree for many years. Use a similar compost to that before advised, and do not over-prune. Black Ischia and Brown Turkey are two fine varieties.

SHAMROCK.

WHAT TO DO WITH GARDEN REFUSE.

THE very best method of turning garden refuse to account is to burn it and apply the resultant ashes to the soil as manure. Experiments conducted for fourteen consecutive years

YOUNG, ERECT-GROWING POPLARS PLANTED AS A WIND SCREEN. THESE WERE RAISED FROM CUTTINGS PLANTED SIX YEARS AGO.

small glasshouses may grow Figs in pots as well as in the garden. The trees would only remain in the house a few months to yield fruits before those in the open air matured theirs; then they must be placed outside, but be carefully attended to. If slightly forced in the first instance, two crops may be grown on the same trees in one year.

Young Trees in Pots.—I will very briefly describe how these should be treated. Repot them in pots large enough to contain their roots and about as large a bulk of soil. Have clean pots and crocks to ensure good drainage; the compost must consist of fibrous loam three parts, and one part brick and mortar rubble. To a bushel of the combined parts add a 5-inch potful of bone-meal. Trees that have been so potted for one year at least and become established in the pots should be subjected to a forcing temperature; not recently potted ones. Manure is not necessary in the compost as all feeding should be

at the Worcestershire Experimental Gardens, Droitwich, have proved that burnt garden refuse is a very valuable manure, so much so that the latest report says "That decayed and burned refuse of the garden when *used alone* on the same ground for fourteen consecutive years is a valuable source of plant food which gives good results about equal to those obtained from an application of stable manure at the rate of 16 tons per acre to the same crops under equal conditions in all other respects."

The above extract shows that the gardener who takes care of his refuse is to some extent independent of stable manure. By burning, old stalks, prunings and similar refuse can be turned into a good fertiliser, and burning, it should be remembered, is definitely destructive of whatever garden pests may chance to be met with upon and about the refuse. A corner of the garden, screened by a rustic fence with climbers up it, will generally provide a hiding-place for the refuse heap. J. F. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Melons.—It is better practice to plant the first batch of Melons directly from the small pots in which they were raised than to pot them into larger pots and plant at a later date; therefore a hot-bed should be made up and the soil placed in position a few days before the plants are ready to put out, for if once they are allowed to become stunted, the prospect of a successful crop will be much reduced. Melons succeed best in rich, turfy loam, into which a small quantity of old lime rubble may be mixed. The depth of soil should not be less than 10 inches, and must be made firm by ramming after it has become warmed through. Another sowing should be made directly each batch of plants is put out if an unbroken supply is desired, and at least two varieties be planted in each house with a view to succession. Eminence and Hero of Lockinge are well worth growing.

The Propagation of Vines.—This is an easy matter, providing a warm pit or house is available for the purpose. The Vine eyes should be inserted in small pots of sandy loam and placed over a gentle hot-bed. They will soon start, and when two or three leaves are formed they should be carefully potted into 5-inch pots. The most suitable soil is turfy loam, a small quantity of old lime rubble, and a little bone-meal. After potting, the plants may be placed over a gentle hot-bed until well rooted, when they must be potted and kept growing in a warm, moist atmosphere. The compost for the final potting should be of a rougher nature, and must be made moderately firm. The temperature of the house may range from 70° at night to 85° by day with sun-heat.

Plants Under Glass.

The Fernery.—Now that the majority of Ferns are at rest, it is advisable to pot the plants as soon as possible. The compost may consist of turfy loam and peat in equal parts, with sufficient sand and fine broken crocks to keep it in a porous condition.

The Bougainvillea.—This plant succeeds better on the roof of an intermediate house than in a warm stove. Here at Frogmore it is trained to the rafters of a cool show house, and given ample space for the development of its drooping flowering sprays. It produces a grand effect throughout the season. The Bougainvillea does not require a long period of rest, and may be pruned back to the leading stems as soon as possible, leaving sufficient well-ripened shoots to cover the wires or extend the plant. Plants in pots may also be pruned and placed in an intermediate house until growth commences, when they may be carefully potted and placed in a temperature of 65°, where the syringe may be freely used during bright weather.

Cyclamens.—The most forward plants may now receive a light top-dressing of Clay's Fertilizer about once a week. Keep them near the roof glass in a temperature of 55° until they are well in flower. Seedlings raised in September and wintered in pans may now be potted in small, clean pots, and placed on a bed of ashes quite near the glass. Syringe them twice daily, and keep a sharp look-out for green fly, which will soon cripple the plants if not destroyed. Seeds may also be sown now to produce plants for flowering next season.

The Flower Garden.

Dahlias.—Now is the time to place Dahlia tubers in gentle heat for the purpose of increasing the stock of any particular variety. A pit with a temperature of 60° will suit them well. When the young shoots begin to grow, they should be fully exposed to the light to promote sturdy growth. When they are about four inches long, they should be removed from the tubers with a sharp knife, and inserted in small, clean pots of sandy soil which has been passed through a fine sieve. The pots may then be plunged in a bottom-heat of 80° and kept close until roots are produced, after which they should be gradually exposed to light and air, and potted into 5-inch pots as soon as ready. Dahlias may also be raised from seed

which should be sown in February. If potted up as soon as ready, they should produce an abundance of flowers from July onward.

Sweet Peas.—Some of the best varieties should be sown in small pots at once for flowering in June. Only a few seeds should be placed in each pot. It is advisable to germinate the seeds in gentle heat, but as soon as the seedlings are through the surface they should be kept quite close to the roof glass, and nothing more than protection from frost attempted. The ground should be trenched, and a liberal supply of good farmyard manure mixed with the soil.

The Kitchen Garden.

Peas.—A sowing of round-seeded Peas may be made now without fear of the weather injuring either seeds or plants, providing a sheltered position is chosen for the purpose. A warm south border, which has been trenched and manured in the autumn, will suit them well. The Pilot is one of the best for this purpose, being very hardy and the quality first class.

Parsnips.—The ground for this crop should be got ready as soon as possible. When dry enough to crumble under the foot, the drills should be drawn 18 inches apart and the seed sown carefully, selecting a quiet morning for the purpose.

Carrots.—A small sowing of Early Gem Carrots may be made on a warm border as soon as the soil is in a fit condition. Protection from frost may be afforded by a light sprinkling of dry Fern, if necessary.

Shallots may now be planted in shallow drills 1 foot apart.

Jerusalem Artichokes.—If not already done, this crop should be lifted as soon as possible. The largest tubers may be placed in a stove, and the medium-sized ones selected for planting. This work may also be done at once.

Cabbage, Brussels Sprouts, Lettuce and Cauliflowers should be sown as soon as possible. If only a small supply is necessary, the seeds may be sown in boxes and placed in a slightly heated pit, or they may be sown in a cold pit, providing the soil is placed in the pit for the purpose.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes may now be planted in most places, provided the ground is at all suitable. In a great many gardens this crop receives but scant attention, and, like the herb border, anywhere seems good enough for the plants. Yet what a difference there is when they are well cultivated. If the ground has not been previously prepared, planting may be done as the digging proceeds. It will be better to defer planting the Chinese variety, *Stachys tuberifera*, till some time in March. To grow it well in the North, it requires to be planted in light soil on a warm border.

Parsnips may now be sown where one can get the soil into working order, but defer sowing should the soil be at all wet. It is a good plan to fork over the soil in the morning and sow in the afternoon. Where Parsnips are required for exhibition purposes, the sowing may be done any time, provided the soil has been prepared beforehand for filling up the holes. Should severe weather set in after sowing, the seed may be protected by small pieces of slate.

Broccoli, in very cold districts, will require some protection. There are a great many ways of doing this, and all more or less good. The method I find most effectual is to use dry leaves placed along the rows, as it is the stalk that suffers from damp and cold.

Celery will also require protecting at this season; and for those who do not have a supply of boards, a very good substitute will be found in ordinary stable litter.

Lettuces.—A small sowing of Lettuces, such as Sutton's Nonsuch, may be made for growing on in frames. They will be greatly relished in spring, when salads are so scarce.

Radishes.—Continue to make a small sowing of Radishes, as, like Lettuces, they are more appreciated in the spring than when one has a surfeit of them.

Winter Spinach.—This Spinach will be greatly assisted by running the hoe between the rows frequently and giving a slight dressing of sulphate of ammonia.

The Flower Garden.

Lobelias.—Where it is intended to raise Lobelias from seed, no time should be lost in sowing, and, as it usually germinates like grass, sow sparingly. Plants that have been wintered in a cool house and are intended for stock purposes should be introduced into heat, so that cuttings may be secured as soon as possible.

Heliotrope.—Where large quantities of this useful bedding plant are required, propagation should start forthwith, so that the earlier-rooted cuttings can be topped and struck later.

Alyssum.—The variegated form of Alyssum is again coming into favour, and as it does not root as readily as one would wish, no time should be lost in getting the stock plants into congenial quarters.

Box Edging.—Where it is intended to make up blanks or replant Box edges, the present is a very suitable time for this work. Preserve all the trimmings that would be suitable for cuttings, and make up a few lines for future use.

Epilobium rosmarinifolium is a charming plant for a marshy spot in the flower garden. It grows about two and a-half feet high, is compact in habit, and does not ramble so much as *E. angustifolium*.

Senecio wilsonianus, with its Eremurus-like flowers, is also a grand acquisition for such places.

Polygonum oxyphyllum, with its snow white plumes of fragrant flowers, should also be included. No collection of bog plants should be without these three.

Gilia coronopifolia.—Many gardeners fail to flower this handsome annual by being too late in sowing. To have it in flower in late summer, the seed should be sown at once.

Calceolarias.—Continue to exercise the greatest precaution in admitting air to Calceolarias after a spell of hard frost. I have seen hundreds go off suddenly through carelessness in opening the lights too freely, and thus giving the young plants a severe check.

Hardy Fruit.

Apricots.—All pruning and tying should now be completed, as in sheltered spots they will soon show flower. If they have not been protected by netting or other material, this should be done at once. A good herring-net, doubled, is as good a protection as any, and this may be kept off the trees with forked sticks placed at intervals along the wall.

Gooseberries.—These may be syringed now with a good winter wash or Quassia Extract. This will go a long way towards keeping them clean and, acting as a preventive of caterpillar. Indeed, where the plantation is not over-large, it will pay to go over them frequently, using an Abol syringe.

Plants Under Glass.

Gloxinias that have been stored during winter may now be gone over and carefully examined for rot. Turn them out of their pots, and place the bulbs in boxes among some leaf-mould. Put them in a warm house, potting them as growth advances.

Caladiums.—Almost the same treatment applies to Caladiums, only they will require a little more liberal treatment.

Malmaison Carnations in 3-inch pots will now be ready for potting in 6-inch pots, provided the soil has been prepared as advised last week. Pot fairly firmly and water sparingly; indeed, they should not require water for some days. Cuttings of the Perpetual varieties, rooted about the New Year, should now be ready for potting on singly. They ought to be handled very carefully and placed on a shelf near the glass. Those rooted earlier may now be pinched well back, which will lay the foundation for a good sturdy plant.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N B

IS THE DAFFODIL A FLORIST'S FLOWER?

"YES" AND "NO."

SOMERSET," in his very interesting articles on "What is a Florist's Flower?" in THE GARDEN for September 13 and 20, 1913, did "Daffodils" and its author well. I sincerely thank him. It is pleasant to feel that my effort has met with a Daffodil-lover's approval, for such I feel my unknown friend must be. As I said in my recent notes, my reply has been simmering. So much is in the pan that if it were all poured out it would fill a whole number of THE GARDEN. A good job it did not, for I must confess I am a florist. In one way we all are. "Somerst" himself is one, else why does he relegate that most charming Santa Maria to the world of poor things. More than once, too, after having heard Mr. Reginald Farrer discourse, as only he can do, on the jollinesses and the good formnesses of some Saxifrage or other alpine, have I chimed in, "Yes, all right; you are getting on. Fancy not being contented with what Nature first gave you. You really are, after all, a florist in disguise." Some time ago I was an onlooker at a scientific committee meeting of the Royal Horticultural Society, when I heard Sir Harry Veitch explain how John Heal had first made a new race of winter-flowering Begonias and then improved it. "Floristy" again. I often think the larger half of mankind are Jesuits at heart, but they do not like to be told so. I feel certain three-quarters of the gardeners of the world, if not seven-eighths, are florists in the sense that they attach great importance to form, size and substance, and almost invariably like a well-filled-up flower to one more scantily endowed. Maximus is preferred to Santa Maria by "Somerst." Probably any jury of twelve would give as their verdict, "So say all of us." A florist, then, in his childhood state is one who is not content with all that Nature has given him. He wishes to change and improve, he will tell you, the vegetable kingdom. He would like to make fruit more luscious and sweet, and flowers more attractive, and if the true spirit is in him, this would be one of his works of maturer years. In our own Daffodil world, what else have Engleheart, the Williamses, Crosfield, Wilson, Brodie of Brodie, Gore-Booth and the whole company of hybridisers been trying to do but to improve the flower? Gentlemen, we are all florists. If so, is not our flower a florist's flower?

One day last summer I was about to be taken over an interesting garden in Kent by its owner and a friend. By way of letting me down lightly and so that I might not be disappointed with the show, one of them said, "Oh, I know you are an arch-florist." I took it as a compliment, for the most arch-florist I ever knew was old James Douglas, and a more charming and gentler-mannered man I have never met. One of the red-letter days of my florist's life is May 5, 1909, the day I spent with him at Great Bookham in the midst of his Auriculas. One of my most cherished books is his "Hardy Florists' Flowers," which he gave me as a memento of the day. No one who has read Horner's touching preface to this little book can ever belittle them again: "A touching history if it could be written would be the nurture and ministry of florist flowers. They have been the delight of many a

man in whom the love of Nature was inborn and inextinguishable, but whose means were very spare, whose leisure time was very scant, and whose advantages in pure air and light and garden space were very poor and cramped. . . . Yet did the Spring smile on him in his Polyanthus and Auriculas and Pansies, and Summer visit him in the bloom of his Tulips, Pinks, Ranunculuses, Carnations and Picotees. In one or more of these, his love of Nature found expression, and enough to live upon." The foregoing are words pregnant with meaning. The Daffodil has had a different upbringing. It has not had to go through the struggling times of the Auricula or the Pink. It has never been a flower of the little back garden or small hired plot; but, nevertheless, there is in the Daffodil-grower the same spirit and the same human nature as in the more humble cultivator of the Pink and the Pansy, and I feel confident that the one great stimulus that has encouraged and still encourages them all in their work is the stimulus of the show. It is the far-off ideal which must never become a reality which lures them on. I quite recognise the possibility of that ideal being a wrong one, but I do say there must be one, otherwise why is not Mme. Plomp the equal of Duke of Bedford, and Duchess of Brabant of Evangeline, and ornatus of Tennyson? Otherwise, why not pick up any Dick, Tom or Harry to judge? Why was I paid to go all the way to Barnstaple last spring to judge the Devon exhibits? Why did not the committee save a big railway fare and get some neighbouring head-gardener to award the prizes? Why? Because the Daffodil is a florist's flower; because, already young as it is, there have grown up certain standards of excellence which I as an expert know and recognise, and according to which I feel bound to judge, and which the ordinary non-specialist will not know. I do not think "Somerst" and I are very far off when we have each of us scratched the other deep enough. One question to him to clinch my argument and to end Part I. Would he prefer the head-gardener at the nearest big place to where he lives to judge a collection of his at a show, or, let us say, Mr. P. D. Williams? JOSEPH JACOB.

(To be continued.)

GARDENING ACROSTICS.

SOLUTION AND NOTES OF ACROSTIC No. 7.

C. CRISPA—PARSLEY.

* 1.	C	OWSLI	P
† 2.	C	OLUMELL	A
‡ 3.	R	ED SPIDE	R
§ 4.	I	MPATIEN	S
5.	S	UN DIA	I
¶ 6.	P	ICTURESQU	E
** 7.	A	NTIPATH	Y

Cryptogramme crispa (syn. Allosorus crispus) is the well-known Parsley Fern which grows among *débris* on many British mountains. It gets its popular name from its resemblance to the familiar Parsley of our kitchen gardens.—See Druery's "British Ferns." * Cowslip balls and Cowslip wine are both made from the Cowslip of our meadows. † Columella, who lived about A.D. 50, wrote upon agriculture and gardening. He wrote twelve books, "De re rustica," and one upon trees, "De arboribus." ‡ The red spider revels in a dry atmosphere and dislikes damp. § The generic name of the garden

Balsam is Impatiens. A popular strain is called the Camellia-flowered. || "I do not rule unless I am ruled" is the motto upon a sundial in Uppingham. ¶ Sir Uvedale Price, who died in 1829, had great taste in laying out gardens. He wrote a celebrated essay on the "Picturesque" in 1794. ** See Bacon's "Sylva Sylvarum" under Century V. In the fifth edition, page 101, sympathy and antipathy in plants are discussed.

RESULT OF ACROSTIC No. 7.

In this acrostic it was possible to get nine marks, one for each correct "first" and "last," and one for each correct light. The following marks have been awarded:

Nine marks.—"Rustic," Wm. Bond, "Bow," "Westbank," "Boarsvale," "Miller" and "Hero."

Eight marks.—"Ping," "Jan," "M. M.," G. D. King, "White Lady," "Elm," "St. Kevins" and "Nautilus."

Seven marks.—R. Chapman, M. Browne, "Penwarne," "Shamrock," Wm. Slocombe and Ernest Ballard.

Six marks.—"W. J. W.," "Brixtonian" and "Rusticus."

Five marks.—"Tempus Fugit."

Four marks.—N. G. Hadden.

Two marks.—"Bees Wing."

ANSWERS

TO CORRESPONDENTS.

FLOWER GARDEN.

PLANTS FOR JAPANESE GARDEN (M. H.).—Frequently where the garden is small, it is not confined to Japanese plants entirely, but a variety of hardy Heaths and Azaleas are made use of as carpeters for Lilies and other plants. In this way Azalea mollis in variety is freely used, also Ledum palustre, Kalmias and the like. Of hardy Heaths you might use the best varieties of Erica cinerea atropurpurea, coccinea, rosea and astrosanguinea. E. carnea (Winter Heath), E. codonodes and E. mediterranea hybrida would be worth growing, too, as they are among the most valuable. Any of the varieties of Lillium speciosum, L. longiflorum, L. elegans and L. tigrinum could be associated with these plants, while Primulas japonica and pulverulenta would be quite at home in wet or damp places. In addition, Iris laevigata should be made much of; there are endless varieties, and no such garden would be complete without them. Japanese Maples and small-growing Bamboos are among other good things. Just what should be planted, and where, depends very much on the size of the garden and how it is laid out.

CHRISTMAS ROSES NOT FLOWERING (A. V. P.).—If after flowering last spring you really did cover the plants with manure, you have probably poisoned them for the time being, and it will take them some time to recover. The entire absence of new leafage during 1913 shows that there is something radically wrong with them; as during that time they would be in a state of decline. This leaflessness, whatever the cause, is doubtless responsible for all shortcomings, the plants having suffered a loss of root fibres in equal proportion. The soil cannot be blamed, seeing the plants have succeeded so well hitherto. All you can do now is to place a handlight over the clumps to encourage the development of the flowers, and, these over, lightly fork about the plants and work into the soil a dressing of lime, which will assist to neutralise the effects of the manure. In all probability there will be but a meagre leaf development this year, as a direct result of the debilitated condition of the plants, and, if so, your remedy will be lifting, dividing and replanting in August next.

TREES AND SHRUBS.

FLOWERING SHRUBS FOR EFFECT (C. T.).—The following shrubs are suitable for your purpose. Back row: Lilac de Louis Spæth, L. Marie Legraye, Berberis stenophylla, Ribes sanguineum atrosanguineum, Laurus tinus, Viburnum Opulus sterile, Forsythia suspensa, Cotoneaster Simonsii, Diervilla Abel Carrière and Philadelphus coronarius. The other row may consist of Daphne Mezereum, Spiraea arguta, S. Anthony Waterer, Diervilla Eva Rathke, Cotoneaster horizontalis, Philadelphus Lemoinel erectus, Hypericum patulum Henryi, Prunus japonica flore pleno, Kerria japonica flore pleno, Berberis walliebiana, B. Aquifolium, and silver and golden variegated Tree Ivies. Do not place the plants very close together, for they will grow quickly. Should the ground appear bare the first season, a few annuals may be planted in the more open spaces.

THE GREENHOUSE.

ADVICE CONCERNING VARIOUS PLANTS (*A Reader*).

(1) In order to grow the very large heads of Hydrangeas, cuttings should be taken in July of the strongest terminal shoots, such as you may feel sure will flower the following season. When rooted, they should be shifted into 4-inch pots and grown in a frame. The original leaves should drop off in the course of the winter. In the month of February the plants should be shifted into their flowering pots, 5 inches or 6 inches in diameter, according to their vigour. A good compost, mainly consisting of loam and thoroughly decayed manure with a little sand, will suit them well. If there is no manure available, leaf-mould may be substituted, giving the plants stimulants later on. After potting, the plants must have a good position in the greenhouse. The small buds are of little account, and may be taken off or left on as you think fit. (2) As you require your *Maréchal Niel* Rose in early spring, we should not prune it in any way now except to remove any weak and exhausted shoots. Under the conditions named, any pruning required had, we think, best be done after flowering. (3) It is very probable that the reason of the non-flowering of your *Passion Flower* is that the roots have an unlimited run, hence the strong growth, while at the same time they are very likely in an unsuitable soil. The plant should certainly be kept free from suckers. We should certainly advise you not to prune the plant now, but to wait until the end of the season, as it may possibly flower during the coming summer. The white markings on the leaves we do not understand, but if you send us a few leaves we can, perhaps, help you in the matter. (4) Good plants of the two species of *Asparagus* named by you can be obtained from seed in about eighteen months, provided (and this is an important item) the conditions are favourable for their quick development. In their earlier stages they are far better suited in a stove temperature than in a greenhouse. If the plants of *A. plumosus* referred to by you are the result of seed sown last year, the pots—5-inch and 6-inch—are much too large for them at present. (5) All the pruning *Lapagerias* need is to cut out any weak and exhausted shoots, if necessary, to prevent overcrowding. The strong shoots pushed up from the base must not be interfered with in any way, except to secure them as they lengthen, in order that no harm comes to the succulent point.

MISCELLANEOUS.

GRUBS IN MANURE (*P. M. H.*).—The grubs and beetles are those common in manure, on parts of which they feed. They are not likely to be harmful to plants.

CHARCOAL AS MANURE (*W. R. F.*).—Charcoal is of slight value as a manure. Its main use in the garden is to mix with the potting soil for plants which have to stay long in their pots, in order to keep the soil open and to absorb vegetable acids, which would tend to make the soil sour. Just as one charrs wood posts to check decay, so charcoal decays but slowly, and parts with equal slowness with any mineral salts that would be of value to the soil.

SOOT AS MANURE (*Anxiety*).—You may use soot direct from the chimney for making soot-water. In buying soot it should be remembered that the lighter it is in bulk, the better, for that is an indication of purity. Its composition varies, but the average value of the nitrogen in it (the only important constituent) is 6d. a bushel. One should expect four bushels to weigh a hundredweight, and at that rate the soot would be of somewhat greater value.

VARIOUS QUESTIONS (*W. S. D.*).—It is possible that Rose Dorothy Perkins would suit your purpose as well as any. All Roses, however, like a fair amount of sun, and you would be best advised to give it as light a position as possible. *Jasminum nudiflorum* may be planted at once, but you had better not plant *Crataegus Pyracantha* until April. You ought also to be careful to procure the latter shrub established in a pot, as it usually transplants rather indifferently from the open ground. *Jasminum nudiflorum* flowers during midwinter, and *Crataegus Pyracantha* blossoms about the end of May. Both plants may be procured from any of the firms of general nurserymen who advertise in *THE GARDEN*. The address of Mr. D. B. Crane is 479, Archway Road, Highgate, London, N.

VARIOUS QUESTIONS (*Trent*).—There is not much to choose between the merits of various kinds of climbing Roses which may be grown as specimen weeping plants; but perhaps for general usefulness Dorothy Perkins takes the lead. *Hiawatha* is also very beautiful when grown as a weeping plant. Most people are guided in their choice by the colour of the flowers. Nothing can be done to your *Ampelopsis* to cause it to retain its leaves later in autumn. The leaves of the large-leaved forms usually fall more quickly than those of kinds which have small foliage. It is usual for the leaves to increase in size and alter in shape as the plants advance in age. Some difference also occurs when shoots from old plants have been used for propagation, as they are likely to form large leaves earlier in life than others which have been raised from plants with small leaves. Plants placed in very rich soil also have a tendency to form large leaves early in life, and it is usual for those growing in poor soil to colour more brilliantly than others which are in good soil. Gooseberry and Currant trees are often planted between Apple trees, with good results, although the crop of fruit may not be up to the standard of that grown on trees occupying more open positions. It would be as well to confine the bushes to the more open parts of the border. In some of the market gardens about London it is usual to plant Lily of the Valley, Christmas Roses, Wallflowers and Narcissi beneath the shade of Apple and Plum orchards.

COAL-ASHES FOR THE GARDEN (*H. S. W.*).—We do not think the use of coal-ashes in the garden, except for the purpose of lightening the soil or for making cinder paths, is to be recommended. Their manurial value is very slight, and they are apt to contain substances poisonous to crops unless they have been exposed to washing by rain for some time. It would be better to weed the lawn, top-dress it with some good soil, and, when growth begins in spring, manure it with some sulphate of ammonia at the rate of half an ounce to the square yard, not more. From what you say with regard to the pests your garden suffers from, we should imagine the soil to be sour and in need of a dressing of lime. When the Carrots are through the soil and the fly which is the parent of the maggot is about, sprinkle along the rows with paraffin-moistened sand, and take care that the earth about the Carrots is not loosened so that the fly can make its way in. The cigar ash, used sparingly, would possibly be beneficial.

WEEDS ON LAWNS (*Learner*).—You can do little good by covering your croquet and tennis lawns with sulphate of ammonia or lawn sand and then resowing them. A better plan will be to have as many of the coarse weeds as possible pulled up by the roots at the present time. The "Champion" Daisy Lifter is a good tool for the purpose. Then in March, in mild weather, proceed to prick the surface of each lawn over with a fork, and then sow it with good seed, afterwards providing a light covering of good soil which is free from weed seeds. A light rolling, when the surface is moderately dry, will complete the work. As the old turf is doubtless full of weed seeds, weeds will continue to appear for some time. These must be pulled up and not allowed to seed. Next autumn give the grass a liberal dressing of bone-meal. This will encourage the grasses to outgrow the weeds. When the grass is vigorous, a dressing of sea-sand occasionally will encourage the finer kinds of grasses to outgrow the coarser kinds.

THE RHODESIAN WISTARIA (*BOLUSANTHUS SPECIOSUS*) (*F. J. H.*).—This is a leguminous tree, native of Portuguese East Africa, Rhodesia and the Transvaal. It is described and figured by C. R. Sim in his "Forest Flora and Forest Resources of Portuguese East Africa," pages 44 and 45. From his description we find that it forms a small ornamental tree, 20 feet to 35 feet high, with hard, white, durable timber, which is used almost exclusively for the spokes of wheels. The leaves are deciduous, pinnate, and made up of from nine to seventeen lance-shaped leaflets. The flowers appear simultaneously with the young leaves in spring. They are usually violet in colour, and borne in long racemes in a similar manner to the flowers of the *Wistaria*. In some districts it is called the Rhodesian *Wistaria*, and, in other places, the Van Wykshout or Maawthlu. It is not common in cultivation, is only grown from seed, and requires good deep soil and a subtropical climate.

PLANTS FOR HERBACEOUS BORDER (*W. S. D.*).—Although your garden is rather shaded, there is no reason why you should not be able to cultivate herbaceous plants fairly satisfactorily. Be careful, however, to well prepare the ground. Trench it from 1½ feet to 2 feet deep, and add manure if at all poor. Should you find that tree roots are likely to interfere with the border, cut them off at a point 2 feet or 3 feet outside the border. This should be repeated every second year. The following plants may be planted, all of which will blossom next spring, summer or autumn, according to season: *Delphiniums* in variety, garden varieties of *Phlox* for the lighter places, *Pæonies*, *Salvia virgata*, *Monarda didyma*, *Lychnis chalcedonica*, *Veronica teurcium*, *V. spicata*, *V. virginica*, *Anemone japonica*, *Asters* in variety, *Clematis recta*, *Galega officinalis*, *Lilium candidum*, *L. tigrinum*, *Helleborus niger* (Christmas Rose) for shady and moist places, *Saxifraga cordifolia*, *Pinks*, *Carnations*, *Lychnis coronaria*, *Acanthus* (various species) and *Oenothera biennis*. The last named is not a perennial, but renews itself by self-sown seeds.

NAME OF PLANT.—*Headly Grove*.—*Moschosma riparia*.

NAMES OF FRUIT.—A. D.—A, Allington Pippin; B, Yorkshire Beauty; C, Winter Peach; D, Blenheim Orange; E, Colonel Vaughan; F, Washington; G, Sugar-loaf Pippin; H, Wellington.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

ALTHOUGH cut flowers are exceedingly scarce just now, there appeared to be no appreciable falling off in quantity at the fortnightly exhibition of the above society held at Vincent Square, Westminster, on Tuesday last. Carnations were the most prominent flowers, and they were shown by numerous exhibitors. There was also a wide selection of Orchids, while *Cyclamen* again were well shown. But the leading feature of the exhibition was the vast collection of Potatoes from Messrs. Sutton and Sons, the famous Reading firm.

FRUIT AND VEGETABLE COMMITTEE.

Present: J. Cheal, Esq. (chairman), and Messrs. J. Willard, E. Beckett, H. Markham, A. R. Allan, A. Grubb, A. Bullock, G. Reynolds, W. Poupert, C. G. A. Nix, J. Basham and James Gibson.

As already mentioned, Messrs. Sutton and Sons staged an extensive collection of Potatoes. No fewer than 150 varieties, all of them in the finest condition, were

shown. The firm's varieties *Carlsbrooke Castle* and *Stirling Castle* were to the fore, as well as a great many promising seedlings under number. The collection was made the more interesting by the addition of wild types and numerous hybrids. Certain Potato diseases, as preserved specimens, including the much-dreaded black scab, were also represented. The high award of a gold medal was deservedly given to this meritorious exhibit.

Messrs. J. Carter and Co., Raynes Park, S.W., received a silver-gilt Banksian medal for an interesting collection of stored vegetables, including Onions, Carrots, Potatoes, Beet, Leeks, Celeriac and Salsify. The Onion-Selected *Ailsa Craig* and Carter's Record were worthy of special mention.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), and Sir Jeremiah Colman, Bart., Sir Harry J. Veitch, Messrs. James O'Brien, de B. Crawshaw, R. A. Rolfe, F. Sander, F. J. Hanbury, R. G. Thwaites, W. Waters Butler, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, J. Cypher, J. E. Shill, W. P. Bound, F. J. Chapman, H. G. Alexander, C. H. Curtis, A. Dye, W. H. White, S. W. Flory, W. Bolton and Gurney Wilson.

A silver Flora medal was granted to Messrs. Sander and Sons, St. Albans, for a group of exquisite Orchids, including *Phalænopsis amabilis* *Illustre* and many superb *Odontoglossums*.

Messrs. Charlesworth and Co., Hayward's Heath, showed many superb *Odontoglossums*, of which *Doris* and *amabile splendens* were the admiration of all who saw them. Silver Flora medal.

A similar award was made to Messrs. J. and A. McBean, Cooksbridge, for a magnificent collection of *Cymbidiums*, in which *C. gottianum* was most plentifully shown.

Messrs. Armstrong and Brown, Tunbridge Wells, also received a silver Flora medal. Their group included many *Cymbidiums*, *Cypripediums* and *Masdevallias*.

Mrs. Norman Cookson, Oakwood, Wylam (gardener, Mr. H. J. Chapman), sent a beautiful collection of *Odon-tiodas*, in which the colours blended harmoniously. *Cypripedium Venus*, with six fine blossoms on the plant, was also shown. Silver Flora medal.

Silver Banksian medals were awarded to Messrs. J. Cypher and Sons, Cheltenham, for magnificent *Cypripediums* and *Calanthes*; Messrs. Stuart Low and Co., Bush Hill Park, Enfield, for *Cattleyas*, *Cypripediums* and *Dendrobiums*; and Messrs. Flory and Black, Slough, Bucks, for very select varieties of *Cypripediums*, *Cattleyas* and *Odontoglossums*.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), the Rev. F. Page-Roberts, and Messrs. E. A. Bowles, E. Hooper Pearson, J. Green, R. C. Notcutt, G. Reuthe, G. Gordon, J. Stevenson, C. Blick, C. R. Fielder, J. F. McLeod, J. Hudson, W. Howe, J. Jennings, W. Bain, J. Dickson, C. Dixon, A. Turner, Charles E. Shea, C. E. Pearson, W. P. Thomson, E. H. Jenkins, W. J. James, W. J. Bean, E. Mawley and A. A. Dorrien-Smith.

Messrs. Barr and Sons, Covent Garden, W.C., showed batches of the early *Cyclamen ibericum*, together with *Crocus* species, *Iris stylosa* in variety, *Snowdrops*, *Freesia refracta*, *Primula malacoides*, *P. obconica* of an excellent strain, and other winter-flowering subjects. The most remarkable item, however, was forced flowers of the mauve-coloured *Darwin Tulip* William Copeland, which in January is most unusual.

Messrs. Stuart Low and Co., Enfield, staged a nice group of Carnations, the best vases being of *Baroness de Brien*, *Satin Robe* and *British Triumph*. Some excellent flowers of Mrs. C. F. Raphael were also in evidence. Messrs. Low also displayed some very fine *Cyclamen* in pans, *Giant White*, *Salmon King*, *Vulcan* and others being noted. A pretty feathered variety, white on carmine ground, was included in the group.

The Misses Hopkins, Shepperton-on-Thames, had a small exhibit of rockwork, on which *Gentians*, early *Cyclamen* and hardy *Primulas* were seen.

Messrs. James Veitch and Sons, Limited, Chelsea, displayed a capital table of winter-flowering plants—the old double white *Primula* (*P. sinensis alba plena*), *Citrus japonica* in fruit, *Azaleas* (of which *Deutsche Perle* and *Mme. H. Siedel* were excellent whites), *Freesia refracta alba* (very fine), the white-flowered *Kalanchoë Dyeri* (a succulent from South Africa), *Lily of the Valley* and other good plants.

Messrs. R. W. Wallace and Co., Colchester, again showed a table of dwarf shrubs suitable for the rock garden. Some of these—*Ilex Perny*, *Thuja orientalis aurea nana*, *Juniperus globosa*, *Grevillea alpina*, *Cotoneaster buxifolia*, *C. thymifolia* and *Thuja orientalis aurea gracilis*—were quite good. Some select shrubby *Veronicas* were also shown.

Messrs. Piper, Bayswater and Barnes, staged a particularly good rockery exhibit, on which the early *Cyclamen* were beautifully colonised. These were chiefly of the *ibericum* section, and in their abundance were very charming. Rocks and rock shrubs were arranged on both sides, *Primulas*, *Origanum*, *Dictamnus* and other plants being noted.

Messrs. G. and A. Clark, Limited, Dover, showed *Primroses* and *Polyanthuses* of an excellent strain, in which varied shades of blue were seen. The richly coloured *Cloth of Gold* was also in evidence.

Messrs. J. Cheal and Sons, Crawley, had a pretty grouping of early *Cyclamen*, *Primulas*, *Primroses*, hardy *Heaths*, and alpinas in variety. The Portuguese *Heath*, *Erica codonodes*, was very charming.

Messrs. Young and Co., Cheltenham, showed a group of *Perpetual-flowering Carnations*, in which *La Mode*, *Marmion*, *Beacon*, and *British Triumph* were seen.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Sweet Pea Number.—Next week's issue will be largely devoted to Sweet Peas. We have secured some particularly interesting articles and illustrations relating to these flowers, and there is certain to be a big demand for that issue. Anyone requiring extra copies would be well advised to order them in advance.

Artemisia arborescens.—There is now a great demand for plants possessing silvery grey foliage. This *Artemisia* is one of the best, and it associates well with all lavender shades. If cuttings are inserted now, they will make good specimens by the summer, and on the approach of frost they may be lifted and potted for decoration indoors.

A Hint about Pea-Sticks.—When these are first received, it is a good method to undo the bundles and lay them in heaps on a spare piece of ground, placing heavy weights, such as logs of wood, on them. By doing so they become flattened out, and are therefore more serviceable, as well as being neater and going further. They may be treated like this either before or after they are sharpened, and are better still if they can remain weighted down until required for use.

Winter Aconites.—These are flowering quite a fortnight later this year than they did last, but we are pleased to find that the colour is much deeper and more characteristic. It is difficult to understand why they are not more freely planted, particularly in grass, or shrub borders, where the rich yellow blossoms are seen to perfection. Outdoor flowers in January and February are none too plentiful, and full use should be made of those that are available.

Raising Dahlias from Seed.—The value of Dahlias for decoration, both for the garden or vases, cannot be over-estimated, and few plants give such a succession of bloom during the summer, although for cutting the single and Collarette forms are generally preferred. Seeds should be sown now and placed in a little warmth; they will then make good plants for putting out in June. The ground they are intended to be grown on should not be heavily manured at the time of digging, as it encourages strong, sappy growth; but a little feeding when they are in bloom will be more beneficial.

A Tree for a Moist Situation.—Those who are desirous of planting an effective tree in a position where the ground is naturally wet, such as the vicinity of a pond or stream which is liable to overflow its banks, might try the variety of the Speckled Alder which is known to botanists as *Alnus incana ramulis coccineis*. It differs from the type by reason of the bark of the young branches and the buds being red, a colour which is very attractive in winter. Moreover, the male catkins are showy, for they also present a ruddy effect, especially before the pollen is ripe.

Like other Alders, it is in nowise fastidious regarding soil, providing it is on the moist side, and has the advantage of many trees by being able to grow in places subject to regular flooding.

The Alexandrian Laurel.—Everyone who cares for plants of interest should certainly have this useful decorative shrub. Of the many evergreens used during the winter, none can equal *Danæa Laurus*, with its graceful and glossy shoots. It is not difficult to grow, and when once established one can freely cut away the elegant shoots. The plant is closely allied to the Butcher's Broom (*Ruscus aculeatus*), being sometimes known as *Ruscus racemosus*; but it is more free and graceful in habit, and better in the rich glossy colour of the leaves and shoots, which have the grace of the airy Willow with the glossy green of the Camellia.

A Beautiful but Neglected Annual.—*Arnebia cornuta* is one of the most interesting annuals for the summer, and yet it is seldom seen. Its curious and yet beautiful flowers are rich yellow, marked with large, heart-shaped, black spots from the base to the tips of the petals, which on the second day turn to a deep maroon and finally disappear with age, leaving the flowers a pure yellow. It is of branching habit, from a foot to 1½ feet high, and blooms with unusual freedom all the summer. It is very valuable for cutting, as the flowers retain their freshness for some time in water. Seeds should be sown now and placed in a little warmth; these will make good plants for putting out at the end of April or early in May.

White-Stemmed Brambles.—The value of white-stemmed Brambles for winter effect is very apparent at Clandon Park, Surrey, where *Rubus biflorus* is planted in large beds by the lakeside. In the autumn the canes were heavily manured, and the results have fully justified the operation. *R. biflorus*, however, will in the course of time be quite outrivalled by the new and graceful species *R. giraldianus*, from China. The latter sends up strong canes 6 feet or 7 feet in height, which bend over and droop to the ground. As the canes are white throughout their entire length, each plant forms a most attractive subject. *R. giraldianus* may be quickly increased either by seed or by layering.

More Money for Wisley.—At the annual general meeting of the Royal Horticultural Society, to be held on Tuesday next at 3 p.m., the following resolution will be proposed and seconded: "The Council of the society be requested to create a special trust fund to carry on and augment the society's work at Wisley, and this meeting would approve of a part of the present surplus funds of the society being allocated to that purpose." All sorts of rumours are afloat as to the exact meaning of this rather nebulous resolution, and we presume details of the suggested augmentation of the society's work at Wisley will be forthcoming at the meeting.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The History of White Heather.—"R. O." asks, on page 42 of January 24 issue, whether there is any reference in any well-known book as to how white Heather came to be regarded as a symbol of good fortune and luck. The Rev. Hilderic Friend, F.L.S., in his "Flowers and Flower Lore," page 279, says: ". . . and even the Heather itself . . . is without any definite story or tradition." From the above I take it that the white Heather is included.—G. C. DUDDRIDGE.

Scarcity of Chrysanthemum Cuttings.—"Avon" refers, on page 31, issue January 17, to the scarcity of cuttings last year, but this peculiarity is noticeable in some varieties this season also, even among those that flower early. A market-grower recently showed me some hundreds of stools of Dorothy Ashley, a beautiful pink of recent introduction; but not a single cutting was visible, nor were there any signs of sucker growths, yet the stock last season produced an abundance of cuttings. Why?—T. W.

Mistletoe Peculiarity.

—I have a plant of Mistletoe 30 inches in diameter on an Apple tree, which is the result of ten years' growth and has never yet borne a berry. The growth is robust, of an intense bronzy green tint of colour. Why does it not fruit, I should like to know?—S. [It is probable that the plant in question bears male flowers only. The Mistletoe is peculiar in that it is sometimes unisexual and at other times bisexual. Our correspondent's best plan is to sow seed on the Apple tree next month in the hope of securing a berry-bearing plant. Seed may be sown by cutting a notch in the bark on the under side of a branch, and carefully inserting the seed therein.—ED.]

Rose Climbing Mme. Melanie Soupert.—It happens so rarely that the Rose-grower on the modest scale can add anything to Mr. H. E. Molyneux's descriptions of the newer Roses that, when the opportunity occurs, I feel that it can on no account be missed. In describing Burrell's climbing form of Mme. Melanie Soupert on page 47, issue January 24, he tells us how much he is looking forward to seeing the flowers in the coming season. I can assure him, good florist as he is, that he will have some difficulty in finding any fault with them. Somehow Mme. Melanie Soupert's charms disarm all criticism, yet many of us must at times have longed for blooms with a few more of the exquisite shell-like petals. This climbing form provides us with, making Mme. Melanie Soupert the finest all-round exhibition and

decorative Rose I know of. My plant has had somewhat hard fare for the last two seasons—an eastern exposure, and a mass of clay and a gravel drive to push its roots into. Yet even under these conditions its shoots are rioting far out of reach up the wall against which it was planted, and of all the blooms I have seen I cannot recall one with a single fault.—R. H. BIFFEN, Cambridge.

Primula pulverulenta Mrs. R. V. Berkeley.—I was interested to see Dr. Macwatt's note, page 42, issue January 24, on this beautiful variety of an extremely popular Primula, and can bear out his statement in regard to it failing to produce seed when fertilised with its own pollen. When it is pollinated with the type, seed is often formed, and a certain percentage come the variety in question, but the majority are *P. pulverulenta*. Two years or so ago, varieties, almost if not identical, appeared in various places among seedlings of *P. pulverulenta*, the seed being saved from plants cultivated in this country. Messrs. Barr and Sons

A BOWL OF ROSE CLIMBING MME. MELANIE SOUPERT GROWN BY PROFESSOR BIFFEN.

offer seed of *P. p. Mrs. R. V. Berkeley* in their catalogue this year, where it is described as "a charming new hybrid, differing from *P. pulverulenta* in having pretty creamy white flowers with orange eye." It is hardly correct to state that it is of hybrid origin, and no mention is made of it coming true from seed or otherwise. I crossed *P. p. Mrs. R. V. Berkeley* with *P. cockburniana*, and seed was only produced in a small quantity; but the reverse way gave ample seed. When both crosses flowered, many were typical *P. Unique*, while 30 per cent. or so were lighter in colour and no advance upon other Primulas in commerce. *P. Unique* crossed with *P. p. Mrs. R. V. Berkeley* gave forms of *P. Excelsior*, but none approached the scarlet *P. Excelsior*, which gained an award of merit from the Royal Horticultural Society last year.—T. W. BRISCOE

Rose Backfisch.—On page 56 of your issue of January 31, in referring to a pretty little Pompon Rose sent out by Peter Lambert of Trier that

had been christened with the apparently "cruel" name of Backfisch, I hinted there might be a reason for the label, and asked that the word might be translated for me. My old German dictionary of schoolday use had failed me, "Baked Fish" or "Fried Fish" not seeming exactly a fitting Rose title! I have not had long to wait. Several post-cards and two letters have already reached me and give me the desired information, in the form of various translations of Backfisch, and which I now hand on for the benefit of those of your readers who may have been, equally with myself, in the dark; and I take this opportunity of thanking those of my correspondents through your columns who did not give me sufficient data to do so personally. They all agree that Backfisch is a word that in this case has not been used in its literal sense; in other words, Backfisch would appear to be a slang expression. One post-card, with no other address than the London

post-mark, reads as follows: Backfisch = a female nut." A second says: "Backfisch is used as denoting a young girl not yet 'out,' and the name was probably given to the Rose before it was 'introduced'!" A third says: "I think you will find it means a half-grown schoolgirl, a boarding-school or bread-and-butter miss." But the fourth correspondent puts the matter so well and writes such a charming letter that I should like to quote his letter in full, but my modesty forbids, and I will only give you that portion dealing with Backfisch. It was addressed to "H. E. M., In a Hampshire Garden, Southampton": "Backfisch, literally brook fish, is synonymous with another very modern word, 'flapper,' both

unknown, I imagine, ten years ago, but used to describe the girl in her teens—in my youth we spoke of 'sweet seventeen.' 'Brook fish' may stand for 'salmon pink,' or something that has not yet ventured into deeper waters, or a tender plant. Hideous! but in these slangy days applicable in modern minds to the sweet little flower you describe." The moral of the above is obvious. One occasionally reads diatribes (I am not sure I have not been guilty of writing one or two myself) against the presumed ridiculous labelling of Roses and other plants with names (in other languages than our own) the meaning of which may not be quite clear to us. I admit I was nearly letting myself go over Backfisch—prudence and a sufficient knowledge of the raiser, Herr Peter Lambert, saved me; but my narrow escape in this case may very well be a lesson to others besides myself.—HERBERT E. MOLYNEUX.

Rose Mme. Edouard Herriot.—I was pleased to see the recent coloured plate of this Rose, which was certainly very good. I am looking forward to seeing it in flower in the open, for I question whether the flowers exhibited were in true form, being grown under glass. Moreover, I do not believe we shall see what Mme. Edouard Herriot can do until we have home-budded stocks, and particularly on the Briar. Past experience with French Roses, and particularly the pernetianas, convinces me that we do not see them in form until two seasons have elapsed.—T. W.

A Beautiful Winter Heath.—Erica carnea præcox rubra is one of the best of the newer varieties of E. carnea which have been selected by Mr. Richard Potter and sent out by Messrs. Backhouse of York. It comes early into flower, and affords us a number of sprays. Its name of præcox is quite borne out by its early flowering. It is a very good variety, the flowers being of a rich rose carmine, with the tips of a good, deep madder brown. When these fine Heaths become a little cheaper they will be of great value. Those of us who have a full set of the twelve varieties distributed appreciate the welcome bits of colour they give in earliest spring or even in late winter.—S. ARNOTT.

Mealy Bug on Vines.—It may interest some of your readers to know how I cleared a vinery of mealy bug. First of all, the Vines were pruned, then the cut surfaces painted with patent knotting; next, the rough bark was taken off very carefully, special care being taken round the spurs. Then the glass and woodwork had a good scrubbing and were washed down with the hose; next, the ironwork was painted with paraffin, taking care not to get it on the Vines. The walls were then thoroughly whitewashed and, lastly, the Vines painted, taking care not to miss the least portion and stopping up every little hole, but taking care of the buds. The paint was made as follows: I got some smooth clay and made it thoroughly dry, then worked it into a fine powder. I procured a pint of coal-tar, put it into a galvanised bucket, then poured on a gallon of boiling water, added a wineglassful of paraffin, and well stirred. I then added the powdered clay a little at a time, and kept it stirred till of the consistency of thick cream, and, when cold, painted the Vines as before stated. I also went carefully over the spurs on bright days, and found one or two insects; but now the Vines are thoroughly free, and I am well rewarded for the trouble that the work entailed.—S. J. S.

Rose Aviateur Blériot.—Mr. H. E. Molyneux, in referring to this climber on page 35, issue January 17, mentions that it is not a very strong grower with him. I almost wish I could say the same, for I planted a young plant three seasons back against a fence with the idea of tying the growths to a pole. As my ramblers are but 3 feet 6 inches apart, the problem with me is how to deal with the octopus-like growths of Aviateur Blériot. Not only does it send up many great basal growths, but these break at all points, the laterals running out in all directions 4 feet to 6 feet. During last autumn I cut away many of these side growths, and have since removed many thin basal growths; but as to cutting out old flowering wood, it cannot be done, for such wood is bristling with new autumn-made growths, some shoots running up 12 feet, others sprawling over into my neighbour's garden and making his path almost impassable. Aviateur Blériot is the most vicious wichuraiana I have ever had to deal

with, owing to its habit of making so many laterals. For general vigour nothing I grow approaches it, except American Pillar and Minnehaha, and as both of these are on a wall, I can deal with them. As Mr. Molyneux states, Aviateur Blériot has beautiful lasting foliage, better than nine-tenths of the wichuraianas, but it does not flower in the same way as the Dorothy Perkins type, and it is rather early. The colour in the bud is fine, but, like all yellow ramblers, it becomes nearly white in due course. From what I have seen of Shower of Gold at the shows, Aviateur Blériot is the same.—T. A.

Thatched Roofs.—With regard to the use of thatched roofs for country houses and out-buildings (see THE GARDEN for January 3, page 1, and January 17, page 31), there cannot be two opinions from an æsthetic point of view. From the window of the room in which I am writing, I have only to turn my head slightly to look upon two very old cottages, some 200 yards or more distant, with projecting porches covered with climbing plants and big front gardens. The roofs of these cottages are of real old brown thatch, which has apparently been untouched for a number of years. I can imagine the change that would be effected by the removal of the thatch and the substitution of slates. At the same time, one cannot help thinking what a home this ancient thatch offers for dust, dirt and vermin. If a new form of roofing is generally to be adopted, it would seem to be in the direction of tiles, the glaring redness of which can be considerably toned down by boiling them in oil before fixing, an operation, in my memory, that was performed with a certain amount of success some years back on a house erected at Kew. With regard to Mr. Kennaway's appeal for the preservation of thatched roofs, the *Devon and Exeter Gazette*, commenting upon it, says: "On the whole, the object of the appeal—securing picturesque—has met with sympathy, but several practical objections have been raised," which are set forward in the following extract from the *Sanitary Record and Municipal Engineering*: "We wish," it says, "it were possible for us to support the appeal, but we are regretfully obliged to admit that the objections against the use of this material greatly outweigh the advantages claimed for it, for thatch is, on sanitary grounds, a material which not only harbours vermin, but when infectious disease occurs in houses covered with it, efficient disinfection is practically impossible. Moreover, it is so highly combustible and incapable of being protected against fire that new buildings should not be covered with it. The disastrous fire at Swavesey, in Cambridgeshire, which occurred during the past year, and destroyed one-half of the cottages in the village which were covered with thatch, while those covered with incombustible material escaped, is too striking a lesson to be disregarded. We venture to hope, however, that officers of District Councils will not hasten to condemn these existing thatched cottages."—JOHN R. JACKSON, *Lympstone, Devon*.

SEASONABLE NOTES ON AURICULAS.

DURING the month of February the general routine will depend entirely upon the weather. If it is cold and frosty, little can be done; but should it keep open and mild, the plants will be very active at the roots, and in consequence must be given more water. We should now aim to keep them just moist, and try to secure that happy medium which is easily obtained by every observant cultivator. It is difficult to describe this condition, but the best advice I can give an amateur is: If in doubt about watering a plant, let it wait until the next day appointed for this purpose. With Auriculas it is not necessary to look through the plants daily at this period of the year.

Offsets.—Towards the end of the month the collection should be examined, and all offsets large enough for removal may be taken off. Some will be quite strong and possess a fair quantity of roots. These can be potted in 3-inch pots, using as a rooting medium good fibrous loam three parts, leaf-mould one part, and a moderate sprinkling of sharp sand. The pots usually selected are known as "long thumbs," and the drainage may either be broken brick rubble or ordinary potsherds, over which is placed a thin layer of loam fibre. These offsets, if given a larger receptacle later on, will make nice healthy plants for next season. Some of the smaller offsets which have no roots should be treated as cuttings by placing several round the side of a pot, and if kept close for a few weeks in a hand-light or frame, they will soon form roots, when they may be potted off in a similar mixture to that named above.

The Uselessness of Top-Dressing.—At one time it was the rule to remove about an inch or so of the top soil from around the old plants and replace it with a somewhat rich compost. I have found that this is superfluous, for no difference could be detected in plants which were top-dressed and those that were left alone. It is, however, advisable to look over all plants that were repotted last May or June, and prick over the surface soil with a pointed stick. Where any of the compost has been washed away or removed with the offsets, it should be replaced.

Cleanliness, Ventilation and Light.—The pots may be scrubbed and new labels written where necessary, while the plants will benefit if given plenty of ventilation; but cold, cutting, frosty winds must be avoided. Light is most essential at this season, and where plants are grown near large manufacturing towns and fogs are frequent, the outside glass should be washed and kept as clean as possible.

Repotting Offsets.—A few offsets will have been removed about last August, particularly from choice varieties, and if proper attention has been given they will now require a larger receptacle. When repotting, see that the woolly aphid is destroyed, and make the compost fairly firm.

Seedlings.—In most collections a few seedlings are raised, and these should be pricked off directly they have made two or three tiny leaves. Boxes or pans are best for them in the early stages, a distance of an inch or so from plant to plant being ample; but, when the foliage meets, they ought to be given separate pots. The seed-pans should not be thrown away as other seedlings will appear later on. T. W. BRISCOM.

TRANSPLANTING LARGE TREES AND SHRUBS.

A FEW weeks' work with a transplanting machine when making a new garden, or when carrying out alterations in existing pleasure grounds, moving large trees and shrubs, will produce an effect for which it would be necessary to wait fifteen or twenty years were the moving done by hand, and only plants of moderate size

1—AN EVERGREEN SHRUB WITH ROOTS AND SOIL BOUND UP READY FOR TRANSPLANTING.

used. Tall deciduous trees—Poplars, for instance—can be moved successfully without having soil adhering to the roots; but with evergreens in particular there should be good balls of soil transferred with them to their new positions. Employing a transplanting machine, rollers, planks and a low, four-wheeled trolley may be utilised, the difference being that the work takes longer with plants of considerable size, the balls of soil are generally more shaken about in hauling, and it is not so easy to place the plant upright in the centre of the new hole prepared for it.

Three sizes of transplanting machines are useful for moving balls of soil weighing from five hundredweight to eight or ten tons. A small machine manipulated by five or seven men, according to the weight of the ball, will move from a quarter to three-quarters of a ton. A machine of moderate dimensions will carry up to one and a-half tons, and requires seven to eleven men to work it. The large machine will carry balls of soil up to ten tons. The Evergreen Oak shown in Fig. 3 weighs about eight tons. The value of being able to successfully transplant large specimens thirty or more years old, such as this, will be at once recognised. The greatest value of these machines is, of course, with evergreens, as these, taken as a whole, are

slower in growth than deciduous trees. There will not be sufficient work for one or more of these machines in a garden of fair dimensions; but when new work or alterations on a considerable scale are contemplated, it is worth while calling in the help of a firm who use these machines, or hiring the machines from them for a few weeks.

Having decided on the size of the ball of soil necessary to transplant a certain specimen satisfactorily, the ground must be marked out and a trench 1 foot wide dug all round the ball. Square balls with rounded corners are the easiest to manipulate with a machine. The depth to dig down will depend on the size of the specimen and the quantity of roots, varying from 1½ feet to 3 feet or slightly more. To hold the soil together, a piece of canvas should be bound round the ball with thick cord and held in position by a few narrow boards, which can be seen placed in position round the balls of the plants illustrated. In the process of moving, any roots damaged must be cut off clean. If larger than a pencil, the cut surface should be tarred over to prevent fungus starting decay. However carefully large specimens are transplanted, in digging round the ball the plant will lose some roots, so to balance this a number of the branches and twigs should be cut out. Make a basin with soil round each specimen as soon as it is planted, and water thoroughly, unless the weather is frosty.

Fig. 1 shows a bushy evergreen tied up and prepared ready to lift

with a transplanting machine. The wheels stand on the planks placed in position at the sides. The two large ropes are seen placed round the two lifting planks under the ball, the four ends being fastened round rollers on the machine. Fig. 2 is a large tree ready for moving on planks and rollers. The wooden rollers run on the two stout planks placed on the ground. One side of the ball is seen lifted with a jack, ready to place the rollers underneath the ball. The tree is hauled by men with a pulley up the planks on to a low trolley, or, if the distance is short, the specimen may be rolled on planks the whole way. Fig. 3 shows an Evergreen Oak weighing about eight tons, slung on one of Barron's transplanting machines, ready for the horses to draw to a new station. Even larger trees may be transplanted in this way. A. O.

THE FIG AND ITS CULTIVATION.

FROM time immemorial the Fig has been considered a fruit worthy of notice and cultivation. It is a native of Mediterranean regions, and flourishes equally well in Southern Europe, Northern Africa and Western Asia.

Records show that this valuable fruit was introduced into England from Italy early in the sixteenth century by Cardinal Pole and planted in the grounds of Lambeth Palace, where possibly its descendants are still extant. This fruit cannot be said to actually flourish in England generally, although in certain places on the South Coast there are instances of standard Fig trees bearing good supplies of fruit. It has been found necessary, therefore, to protect trees growing out of doors further North, and away from the soothing influence of sea breezes, from the ravages of frost and cold, so they may be regarded as wall fruit.

Propagation.—This may be carried out in several ways, but the methods most generally used are layering, making cuttings or using suckers. In the case of the last mentioned, the wood is sometimes very soft, so it cannot be so highly recommended as either of the others. For cuttings, short-jointed, well-ripened wood should be used and placed in a cold frame free from frost until early spring, when they may be introduced into a brisk heat. Roots will soon be forthcoming, and the usual treatment will then suffice. The practice of layering is convenient, for quite a large branch may be so treated, and therefore a good-sized tree obtained with little trouble. The other means of increase are by seeds, root-cuttings and by grafting, but they are little used.

2—A LARGE TREE READY FOR MOVING BY MEANS OF PLANKS AND ROLLERS.

Cultivation.—With regard to outdoor treatment, the wall chosen for the plants should have, if possible, a southern or south-western aspect, but they may also be grown in an eastern position. The essential factor in the preparation of the soil is perfect drainage. In preparing quarters for fresh trees, the condition of the subsoil should be ascertained, and if cold and retentive, plenty of broken bricks and old mortar rubble should be introduced at the bottom of the trench, which need only be 30 inches deep. In order to check too rampant a growth, it will be found best to mix ordinary garden soil with new loam, making the whole firm as the work proceeds, and continuing to use a goodly share of lime rubble in the compost. A brick partition should be built round the trench at a distance of about two feet from the wall, to assist in preventing the roots from growing too freely. In cold districts the Fig is decidedly better for some protection during the most severe weather. The branches need only be covered with mats just nailed over them during very sharp frosts, but the roots must be covered during the whole of the cold season with a liberal dressing of half-decayed manure, and this should be covered with slates when heavy rains are frequent, as everything depends upon keeping the roots warm and fairly dry. Successful under-glass culture is comparatively easy of attainment, provided one or two practical points are kept in view. (a) The root-run must be restricted and the compost should be only moderately rich to begin with; (b) the border must be made quite firm and (c) the drainage must at all times be in perfect condition. Excellent results may be obtained also from growing in pots and tubs.

Pruning.—For outdoor culture this chiefly consists in cutting away right from the base weak and unnecessary wood. While an effort should be made to retain the main branches, as much good wood as possible should be encouraged yearly from the base, and this should be allowed to grow unchecked throughout the season. The system adopted under glass must necessarily be more orthodox. Assuming the house to be liberally covered with branches, the young wood must be pinched at the fourth or fifth leaf, and all unnecessary shoots pulled off, as overcrowding of the wood is fatal to good Fig culture.

Watering must always be carried out most judiciously, and unless the grower is sure that his border (or other receptacle) is efficiently drained, it will be found safer to apply too little rather than too much, especially during the early stages of growth.

Pests.—The most troublesome are red spider and mealy bug. A free use of the syringe will do much to keep the former in check, but for mealy bug it is best to dress the trees while in a dormant state with some approved insecticide.

Varieties.—For outdoor culture the best is Brown Turkey, while White Marseilles and Angelique also do well. (The latter should have a south wall.) For growing under glass, Brown Turkey is difficult to beat and should be included in every collection. Others to be noted are White Marseilles, Angelique (very early forcer), Black Ischia (early), Monaco Bianco (midseason), Colli-Signora Bianca, Agen (late), and Negro Largo (suitable for tubs or pots).

Planting may be carried out under glass any time between October and March; out of doors, early in the autumn or during February or March.

H. TURNER.

Serlby Hall Gardens, Bawtry, Yorks.

SELECTION OF VEGETABLE SEEDS.

I SHOULD like to supplement the excellent selection of varieties given by Mr. Beckett on page 15, January 3 issue. Now that there are so many varieties to choose from in almost all sections, it is bewildering to the inexperienced to select the best. Some growers for exhibition may say all varieties suitable for that purpose are also the best for daily use. That may be quite correct under ordinary treatment, but when grown under exhibition methods the conditions are altered.

Broad Beans.—Longpod for general growth and Mammoth for exhibition are all that is required.

French or Kidney Beans.—For forcing early in pots or pits Sutton's Forcing is a rapid-growing Bean, and Osborne's is still a desirable variety, with Ne Plus Ultra. For summer growth in the

I prefer a smaller type like Scrymger's Giant and Imported, which give abundance of hard, button-like sprouts, so much more preferable for table than the Cabbage-like article often favoured on the show table.

Borecole or Kale has become an important vegetable, adding variety and giving huge crops. Of the large, curly type Sutton's Ar is desirable, but for a constant supply through the winter and early spring, when green vegetables are not over-abundant, I prefer the true Labrador Kale.

Cauliflowers are an important crop. For sowing indoors Early Forcing and Snowball are reliable, with Autumn Giant as the best for ordinary summer cultivation.

Cabbage.—For an early supply Early Rainham, Sutton's Earliest and Little Gem, with Wheeler's Imperial and Enfield Market for a late supply. If more variety is required, Sutton's April and Flower of Spring are excellent for August sowing, to come in as a succession between the earliest

3.—AN EVERGREEN OAK, WEIGHING ABOUT EIGHT TONS, SLUNG ON A LARGE MACHINE READY FOR TRANSIT.

open Superlative and Masterpiece are both good sorts of a larger type. Climbing French Beans are useful, as they continue to bear for a long time and may be employed to blot out an unsightly object, as they grow 6 feet high. Earliest of All and Epicure are desirable sorts.

Runner Beans can now, with careful cultivation, be had in July, and continue right up to the end of October. Ar, Hackwood Park and Best of All are good sorts in addition to that mentioned by Mr. Beckett.

Broccoli.—Carter's Autumn for an early supply, followed by Self-protecting, Leamington, Knight's Protecting and Late Queen for the latest, are ample, with the addition of Purple Sprouting, which gives added variety and lasts a considerable time without running to seed.

Brussels Sprouts are such an important winter vegetable that the best should be obtained. Where larger sprouts are required for exhibition, Matchless and Exhibition are superior. For home use

and late. Savoy Earliest of All comes in very quickly, almost too much so. Reliance and Dwarf Green Curled are suitable for small gardens.

Carrots are indispensable. Champion Scarlet Horn and Early Gem for sowing in frames, with Scarlet Intermediate for larger outdoor growth, or for exhibition early or late. Where extra heavy crops are required, combining them with a supply for cattle as well as for the kitchen, Long Red Surrey should be grown.

Celery.—Sulham Prize Pink and Superb White are two desirable varieties for ordinary cultivation.

Cucumbers are well represented by a good form of Telegraph for ordinary use, or Every Day or Delicacy for exhibition.

Leeks.—The best variety for exhibition is Improved Lyon. If, however, Leeks are only required in an ordinary way, Musselburgh is desirable.

Vegetable Marrows.—Tender and True of the bush class type is good, and so is Long White

Table Dainty in the coloured section is excellent. Pen-y-byd is very productive, with almost globular fruit, creamy white in colour. This variety requires but little space, therefore is valuable.

Onions.—For exhibition in June and July White Leviathan is desirable. For August and onwards Ailsa Craig is superior to any other. For home use Giant Rocca matures early. For autumn, winter and spring Maincrop is a superior variety. For pickling, if anything is wanted beyond the small bulbs of the last named, Improved Queen and Small Paris Silver Skin should be chosen.

Tomatoes.—The best red variety for exhibition is Perfection, and for general use out of doors Up to Date is decidedly good. Winter Beauty is a good winter-fruited variety. In yellow-skinned sorts Golden Nugget, Golden Perfection, and for the open wall Carter's Golden Sunrise and Green-gage are desirable.

Potatoes.—For early use Veitch's Early Ashleaf, Sharpe's Victor, Duke of York and Sir John

variety, produces large Peas of excellent flavour, and is almost immune from mildew.

Lettuce.—Of Cos varieties for summer use Mammoth White, Superb White and Dwarf Perfection are good. For winter growth Black-seeded Bath, Champion Brown and Winter White are to be depended upon for a constant supply. Of Cabbage varieties Favourite, Commodore Nutt, Heartwell and Ideal, with Golden Ball if more variety is required, are all desirable. Marvel, All the Year Round and Hammer-smith Hardy Green are good for autumn sowing.

Swanmore Park, Hampshire. E. MOLYNEUX.

A BEAUTIFUL KNOTWEED FOR THE ROCK GARDEN.

POLYGONUM AFFINE.

THE genus Polygonum is a most variable one. Some of the species are imposing giants, like *P. baldschuanicum*, the beautiful rampant climber

HINTS ON GROWING ANNUAL FLOWERS.

TO many readers of THE GARDEN the lengthening days will bring serious thoughts of preparation for future floral display. In the majority of gardens, no matter the size, annuals are now deservedly grown. They serve many useful purposes, as, for instance, in a new garden to which one may have recently removed, a quite luxuriant and beautiful display can be secured even the first season; or they are serviceable in filling gaps during the growth of more permanent inhabitants. But, however used, their value is undoubtedly great. According to taste, some may prefer masses or beds of annuals, while others like to scatter them as specimen plants among their border perennials. Both methods are good, the former in the larger and the latter in small gardens; or the two plans may be judiciously employed, and fine results accrue. It may be

that some rather under-estimate the true value of annuals owing to their small cost, and treat them accordingly, while to others this is an important advantage. Many of our most glorious annuals are, however, quite cheap, and it is hoped that any who read these lines and who have not done so will try a few of the varieties which will be enumerated.

Preparing the Soil.—In gardens where digging has not been completed, this should be pushed forward in all open weather, especially on heavy land. Whether light or heavy, however, expenditure of the labour incidental to "double digging" will be amply repaid in the quality of the blooms and the length of their flowering. If clayey, the soil should have a liberal supply of horse-manure well mixed in—country road sweepings are useful—and the top left in rough ridges for the frost to penetrate. Light soils can be dug in February and March, and some cow or pig manure well incorporated. A dusting of old soot and bone-meal put on in spring will be found beneficial on all

soils. An exception to this general application of manure occurs in the case of Nasturtiums, which make much leaf growth in rich soil at the expense of flowers.

Selection of Varieties.—After the preparation of the ground comes the consideration of varieties, and as the amateur is apt to be at a loss when given a multitude of names, in the following selection will be found some of the finest hardy kinds of proved merit, easily grown and floriferous: Sweet Peas are best grown by themselves. Shirley Poppies are good either massed or dotted about. Thinned to 12 inches apart and each plant staked, they do well almost anywhere, and will be found to be worth a little care. To make the cut flowers last, gather them when opening in the early morning, place the stalks immediately in half an inch of boiling water for two minutes, then transfer them to cold water. They will then keep well for some days. *Nigella damascena* Miss Jekyll, *Coreopsis tinctoria*,

POLYGONUM AFFINE IN THE WISLEY ROCK GARDEN.

Llewelyn are desirable as second earlies. Webb's New Guardian is a reliable cropper, and so are Sutton's Satisfaction and Abundance. For late use Dalhousie is reliable. Of newer sorts, several of the pedigree seedlings introduced by Messrs. Sutton are desirable. As a second early I can recommend Stirling Castle as an extraordinary cropper of capital quality, and Edinburgh Castle, Balmoral Castle and Dover Castle as a succession.

Peas.—When three seed firms catalogue 151, 100 and 89 varieties, there is small wonder if the inexperienced person finds a difficulty in making a selection. For early sowing Early Giant, Pioneer, Early Morn, The Pilot and Edwin Beckett. For general use as second earlies Masterpiece, Webb's New Kaiser and Alderman are difficult to beat. For the latest supplies The Gladstone, Ne Plus Ultra, Latest of All and Goldfinder are not excelled. The latter, although a short-podded

from Bokhara, while others are of low trailing habit, spreading naturally over rocks and boulders. It is to the latter group that *P. affine* belongs. It does not attain more than 6 inches in height, and its spreading mass of deep green foliage makes it a capital plant for clothing rocks, while it may also be used with charming effect as a substitute for the Periwinkle to cover banks or low tree stumps. Moreover, it is very free-flowering, for in late summer it produces a wealth of rosy crimson flower-spikes. In the accompanying illustration Polygonum affine is shown growing with remarkable freedom in the Royal Horticultural Society's new rock garden at Wisley. It is a native of the Himalayas, and so hardy is it in constitution that, once established in a garden, no fears need be entertained about its future except that it will need to be kept within bounds, for it is apt to spread too readily.

Sweet Sultan, Godetias Lady Albemarle and Duchess of Albany, Clarkia Salmon Queen and Chrysanthemum coronarium tricolor. For mixing in bunches: Gypsophila elegans grandiflora alba and Eragrostis elegans (Love Grass). For climbing purposes: Tropæolum canariense (Canary Creeper) or T. lobbianum and Convolvulus major (Morning Glory). For edging: Virginian Stock, Candytuft and Sweet Alyssum. For perfume: Matthiola bicornis (Night-scented Stock); sow pinches of seed in out-of-the-way corners at intervals during the season. The foregoing can all be openly sown, and, except the varieties named for special uses, are of medium height. In a future article some of the best half-hardy annuals will claim attention. B. W. LEWIS.

NOTES ON CHRYSANTHEMUMS.

It is many years since the blooms of these plants were as scarce, and consequently as much appreciated, as they were during the Christmas season.

Owing to the mild weather, which brought on other kinds of flowers very quickly as well as some of the late-flowering Chrysanthemums, and then the spell of severe weather abroad, blooms were at a premium. Such a condition may not obtain again for many years; but whether it does or not, cultivators will be wise if they include in their collections good batches of late-flowering varieties. Amateur cultivators should

Propagate the Main Batch of Cuttings Now.—Much use can be made of the garden frame, in which the young plants will do nicely. Being practically hardy, a few mats will protect them from frosts. Plants intended for exhibition purposes should be propagated singly in small pots, but all others will do well if several cuttings are inserted in a 3-inch pot. If this is done, valuable space at this season will be saved.

Potting Rooted Cuttings.—It is very rare indeed that all the cuttings inserted at the same time will be ready for potting on the same date. Some are stronger-growing varieties than others, and the cuttings of these, if not too sappy, will form roots and be ready for potting about a week before the weaker-growing sorts. Every young plant must possess a nice lot of roots; it is then fit to repot. If left too long in the small pot it becomes stunted and the stem hardens unduly. It is owing to such a check that one often finds plants with thin stems about 6 inches above the pot and thicker higher up. Keep all young plants growing steadily and well up to the light; if grown in a greenhouse, place them on shelves.

Rooting Border Varieties.—Early in February put in the cuttings of the border

varieties. Shallow boxes may be used. Put in a thin layer of well-rotted manure, then a good compost surfaced with sand. Insert the cuttings 2 inches apart, water, and shade from bright sunshine. The cuttings will form roots in about twenty days if the boxes are placed just above the hot-water pipes, and in a month if accommodated in a cool frame.

AVON.

CANARINA CAMPANULATA.

ALTHOUGH seldom seen in cultivation, Canarina campanulata is a beautiful greenhouse plant

AN ATTRACTIVE GREENHOUSE PLANT, CANARINA CAMPANULATA, NATIVE OF THE CANARY ISLANDS.

of comparatively easy culture. It is named Canarina from its habitat, being a native of the Canary Islands, while the specific name obviously refers to the large, bell-shaped flowers that are rather sparsely produced from January to March. The drooping flowers vary in colour, but are usually of an orange hue and netted with red veins. The plant is of a semi-climbing habit, not free enough to train to the rafters of a greenhouse, but it may well be trained around stakes about two feet in height. A compost of loam, leaf-mould and silver sand makes a suitable rooting medium. It is increased by division at the time

of repotting, that is, usually, in December, or by young cuttings taken in the spring and inserted in sand in a warm propagating-case.

THE HERBACEOUS OR MIXED BORDER.

HOW TO MAKE AND MAINTAIN IT.

(Concluded from page 60.)

Borders of One Colour.—Touching on one-colour gardens, the authoress of a recent volume on herbaceous plants states she has never seen one that gave her satisfaction. That in general is perhaps too sweeping a statement. To a great extent it is, however, true, and unless the composer is absolutely sure of the colours of the various plants, and also their disabilities as mere plants, as well as their strong points, one-colour schemes are assuredly speculative. The least difficult, which is equivalent to saying the colours harmonise best, are yellows running from cream to dark brown, and pinks to crimson, blues being the least satisfactory, probably on account of the sparsity of plants to choose from. A very charming composition is effected with yellow and white, being careful to reject dead whites and choosing yellowish and greenish whites. The past season I introduced deep pink among yellow, with which it goes very well. Another combination of a few simple colours that is very satisfying is of mauve, violet and pink to rose salmon. White and mauve of varying depths of tone are also worth trying. But it must be understood that in each and every one of these the range of plants is limited, not so much because the number of species or varieties is few, but because one must be sure of the proper shades, and wherever or whenever it happens that one or more plants of a wrong note are introduced, then removal and substitution must take place as soon as the mistake shows itself. On the whole, for general purposes a mixture of colours is to be preferred,

and more particularly for borders which are kept gay for a long period. In these it is possible to plant so that special colours may give a character to the border at different times—the Daffodil season, yellow; Delphiniums, blue; Asters, grey. A

Study of Floral Colours shows that strength is essential, especially in blues. The blue of Cornflower at a distance fades to grey, and lovely as is the blue of Endive and Succory, the general effect is the same or a little less pronounced. Therefore, to secure a telling blue effect in a large border, that of Aconitum autumnale and Larkspur

should be chosen in preference to true blues. Two of our borders were planted with various mauve plants last season, with lavender and single blue Asters to give tone. Both the last named failed, and the effect was rather dull. The new lavender East Lothian Stock would have been better than either of these. In pinks it hardly matters how faint the shade may be. They are always effective, but to get the desired effect at a distance it is essential to employ a deeper tone, though there is a danger of happening on magenta. *Lilium tigrinum*, *splendens* especially, affords a nice effect which attracts the eye. Orange African Marigold is also valuable, and an even deeper tone is given by *Montbretia Vulcan*, one of the best for border decoration and almost similar in colour to *Helc-nium macrocephalum cupreum*. *Tithonia speciosa*, if not so shy to flower, would be an invaluable plant, deeper in colour than any of the above. For scarlet we can go to Dahlias, to Carnations, Pentstemons, Gladioli, *Gilia coronopifolia*, *Antirrhinums* and Phloxes for the very best. Phloxes are also valuable for violet and plum colours.

In Arranging Colours it is not unusual to employ white to deaden the jar incident to two or more colours clashing. It is a simple expedient, but not to be generally commended. It is very much better to work out schemes in which white need be used only for its intrinsic value, the number of plants available for colour contrasts and harmonies being far beyond the requirements of any garden. White in conjunction with blue of all shades is much to be preferred to white with reds. Cream goes very well with blue, and a few years ago I had the common Gardener's Garters run through clumps of *Salvia patens*, which found many admirers. In arranging clumps for effect, one should always endeavour to get the best. Tiger Lilies, for example, are sometimes arranged with white and with red. But the best effect is derived from brown, which is secured by a good strain of French Marigolds, some of which are a dark mahogany.

Other Combinations of the greatest value are those of plants of one colour, but of different habits and heights. Thus, *Ageratum mexicanum*, either dwarf or tall, goes well with a Larkspur of the same shade, also with *Statice incana*, also mauve. I had last season dwarf *Ageratum* with *Aster Amellus bessarabicus*, and in other colours there are very many plants which are equally desirable arranged together. It must be understood that these combinations are not simply for bedding effects, but parts of the floral arrangement of ordinary mixed borders. Another very charming plant not nearly so much used as its merits deserve is *Verbena venosa*. Not only is the colour—violet—good, but the habit of the plant gives it an additional value for mixing

with other plants taller than itself or of equal height. With mauve it is very pretty, but better with deep rose or light salmon. It is easily raised from seeds, which sometimes lie a long time before they germinate, and also by means of root cuttings, while in many parts of the country it comes through the majority of winters with the help of a little surface protection.

The writers who ridicule the custom of using the same plants or colours over and over again in a border have never discovered how an extensive border is to be well furnished by any other means. Nor is there any need to limit that style of planting, provided the same plants are

give an effect which dwarfier plants fail to give. Some years ago I had pure white, and the effect was, as one gentleman said, bordering on the unreal. *Rose Queen* is also a thoroughly effective variety, and if one could be certain that singles would come true from seed, there would be the loveliest effects conceivable by planting in this way. I have already mentioned

Sweet Peas as a backing for mixed borders, and these in selected colours may be used in those, with another backing trained pillar fashion and near the back, with very good effect. Only it is essential the colours be carefully chosen so that they do not clash with the scheme in general. A plant of *Tropæolum aduncum* run through the Sweet Peas may be permitted; the flowers brighten up the pillars exceedingly. In conclusion, be chary to admit any plant the merits of which have to be discovered. "None but the best," no matter how common they are in colour and habit, must be the motto. Have new combinations every year to ensure the interest of a jaded constituency; cultivate the soil in the most thorough manner; weed out undesirables as they make themselves known for what they are, and replace with better; and never be ashamed to ask advice from those whose colour sense is better educated than your own.

R. P. BROTHERSTON.

Tyninghame, Prestonkirk, N.B.

CYPRIPEDIUM DESDEMONA, A NEW AND BOLD VARIETY WITH A BROAD DORSAL SEPAL AND WAVY WINGS.

NEW ORCHIDS.

ONE of the most striking novelties at the exhibition of the Royal Horticultural Society held on January 27 was the new *Cypripedium* named *Desdemona*, shown by Messrs. Charlesworth and Co., Hayward's Heath. One plant only was shown, carrying a massive flower the general colour of which was a bronzy green. The raisers of new *Cypripediums* aim to procure flowers with ever-increasing breadth in the dorsal or hood, and this character is very pronounced in the variety *Desdemona*, which was granted an award of merit. In this variety the dorsal has a white, undulated margin, while deep chocolate markings over a groundwork of amber and green occupy the centre. Messrs. J. and A. McBean of Cooks-

bridge gained the high award of a first-class certificate for a lovely variety of *Cattleya* Tityus named A. McBean. The variety was a great improvement on the type, both in colour and form. Mrs. Norman Cookson, Oakwood, Wylam, gained two awards of merit for *Odontiodas* with the varieties *Doris* and *Sibyl*, these being the pick of an excellent collection, in which the rich colour tones of the densely marked flowers blended in perfect harmony.

On this occasion no awards for novelties were made by the floral committee of the Royal Horticultural Society.

arranged differently and with other combinations. Some plants may be used in every little gap without giving the least feeling of sameness. Such are tall *Antirrhinums* of a colour that goes well with the majority of the other plants, yellow, crimson and yellow, and white for preference. *Lobelia cardinalis* and Stock-flowered Larkspurs are others; and if one desired a pronounced blue effect, there is nothing better than the double blue form of the last named planted here and there all over the border. A special colour in Hollyhocks if run through the border is also valuable, and more so because the tall spikes

GARDENING FOR BEGINNERS.

FLOWERING SHRUBS FOR SMALL GARDENS.

FOLLOWING my article which appeared on page 601 of November 29, 1913, issue, I give herewith another dozen shrubs suitable for small gardens.

Cytisus præcox.—Some people object to this on account of the somewhat disagreeable smell of its cream-coloured flowers. But it blooms so freely and grows so luxuriantly that it should be included in all shrubberies. It blossoms in May, and can be grown nearly anywhere and in the poorest soil.

Syringa vulgaris Souv. de Louis Spæth is one of the best of the garden Lilacs. It grows quite 2 feet high if planted in good, loamy soil, and bears immense heads of reddish flowers in May. All sucker growths must be removed from the base.

Syringa persica.—Everyone who sees this shrub wishes to plant it. It is a miniature Lilac growing from 2 feet to 4 feet high, with an ample system of slender branches, which bear a profusion of elegant panicles of fragrant, lilac-coloured flowers in May. Plant in ordinary loamy soil and do no regular pruning.

Sophora viciifolia is a new Chinese shrub which grows at least 6 feet or 8 feet high, producing dainty, pinnate leaves and white, violet-shaded, Pea-shaped flowers in June. It must be given good, loamy soil, have no root disturbance, and receive no regular pruning.

Cydonia Maulei superba is a very rich coloured Japanese Quince. It forms a bush of spreading outline 6 feet or so high. The flowers are rich red in colour, and mature during March and April. If planted in ordinary good garden soil, it gives no trouble and requires no pruning.

Philadelphus Lemoinei erectus may be considered one of the best of the dwarf Mock Oranges. When planted in rich, loamy soil it forms shoots 2 feet to 3 feet long in a single season, which bear fragrant, white flowers from almost every leaf-axil in June. As soon as the flowers fade, all flowering shoots must be cut away to allow young ones to grow from near the ground.

Escallonia philippiana is the hardiest of the Escallonias. It forms a deciduous bush about three feet high, and bears a profusion of white, Pea-shaped flowers in July. Ordinary good garden soil suits it, and no regular pruning is necessary.

Berberis stenophylla.—Perhaps if any one shrub is more generally useful than another, it is this, for it is a good evergreen and a first-rate flowering shrub. In ordinary garden soil it grows to a bush 6 feet to 8 feet high, with a very wide spread, and is useful as a specimen bush and as an occupant of the shrubbery. It stands pruning well, and is sometimes used for hedges. No regular pruning is necessary. It must be placed in a permanent position while quite small. The fragrant, golden blossoms are borne in profusion in April and May.

Hypericum moserianum is a dwarf St. John's Wort of hybrid origin. It grows from 12 inches to 15 inches high, and bears large, golden blossoms during the summer and autumn. Plant in good, loamy soil, and cut back and thin out the branches in spring.

Robinia hispida inermis is the best form of the Rose Acacia, an American shrub with bunches of rose-coloured, Pea-shaped flowers which mature in June. Planted in loamy soil it grows well and blossoms each year. It must not be exposed to rough winds, and does not require pruning.

Ceanothus Gloire de Versailles.—Of the numerous kinds of summer and autumn flowering Ceanothuses this is one of the best, for its large panicles of blue flowers are borne continuously from July to November if the weather continues

generally grown in a greenhouse. It is mainly a question of the proper preparation of the plants several months before they are required for the actual work of planting.

Suitable Plants for the Purpose.—Bougainvilleas, Plumbagos, Palms, Fuchsias, Cannas, Swainsonas, Fatsia japonica, Dracæna indivisa, and Heliotrope. Small plants are not of much use; they must be pyramid-shaped, half standards or standards, with main single stems for preference.

Repotting.—A compost of fibrous loam, leaf-soil, rotted manure and sand will do nicely. This must be made firm when potting is being carried out. Fuchsias should be started in the same way and receive a pruning; but when the young shoots are an inch long the plants must be turned

CYTISUS PRÆCOX, A MAY-FLOWERING BROOM SUITABLE FOR A SMALL GARDEN.

mild. In the open it grows about four feet high, and against a wall three times that height. It must not be planted in very cold places. Ordinary garden soil suits it, and the branches must be cut back fairly hard in February each year.

Cotoneaster rotundifolia.—This Himalayan shrub is not planted for the sake of its flowers, but for its bright red fruits, which ripen in September and hang until spring. It forms a bush 3 feet to 4 feet high if planted in ordinary garden soil, and does not require pruning.

It will be noted that Rhododendrons, Heaths and other shrubs of a like character have been omitted. The omission is due to their unsuitability for soil containing lime.

PREPARING GREENHOUSE PLANTS FOR BEDDING.

In sheltered positions in the flower garden charming effects may be secured by using plant

out of the pots and the old ball of soil much reduced, so that the cultivator may be able to place the roots in a smaller pot, as it will be necessary to repot these plants into larger pots once prior to planting them out.

The roots of Cannas must now be placed in gentle heat to induce a steady, sturdy growth. When all have made good progress, gradual hardening must be commenced at the end of April, so that all will be in a fit condition to transfer to the flower garden the first week in June.

Plants from Seeds.—Seeds of Zea japonica variegata, Ricinus Gibsonii (Castor Oil Plant) Centaureas, Nicotiana affinis, N. Sanderae, and others possessing fine foliage, should be sown, and the resultant seedlings grown on in a rich compost. They must be grown to possess large well-coloured leaves, and to this end avoid any check to growth, and very carefully harden the plants so as to retain the lower leaves. Avo

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Figs in Pots.—Trees that were started into growth early in December will now be sufficiently advanced to benefit by frequent applications of manure-water from the farmyard. Fig trees require a large quantity of moisture at the roots during the growing season, and, when this is applied, sufficient should be given to moisten the soil to the drainage.

Cucumbers.—If seeds were sown at the beginning of the year, the plants should now be ready to put out. Let the house be thoroughly cleaned and the walls whitewashed with hot lime. A hot-bed of leaves and stable litter may then be made up and small mounds of soil placed 4 feet apart on the surface of the bed, which, when finished, should be within 18 inches of the trellis.

Tomatoes.—Plants raised in October and wintered near the glass in 6-inch pots should now be showing flower and ready for their final potting. Ten-inch pots are best for the purpose. The soil may consist of three parts turfy loam and the remainder of leaf-soil. Another sowing may be made now for succession. The first day of March is quite early enough to sow seeds of approved open-air varieties.

Pot Vines.—Early pot Vines will now have set their fruits, and will require careful treatment. Top-dress the pots with loam and cow-manure, and give frequent waterings of liquid manure from the farmyard; but care must be taken that this is not too strong, or the young roots may suffer in consequence. Six medium-sized bunches will be sufficient for each Vine to carry, and these should be distributed evenly over the Vine. Stop the strongest shoots at the second leaf beyond the bunch, in order to give the bunches near the bottom of the trellis a chance to develop. A temperature of 70° at night and 85° by day with sun-heat will suit them well.

Plants Under Glass.

Amaryllis Bulbs intended for flowering during the spring and early summer should be examined, the old soil carefully removed, and the bulbs potted in a compost of light, turfy loam and old lime rubble. Make the soil moderately firm in clean, well-crooked pots. If required, the first batch may be placed in gentle bottom-heat at once to start them into growth. Overpotting must be avoided, as they flower quite freely in 6-inch or 7-inch pots, and are better suited for decoration.

Chrysanthemums.—The earliest batch of cuttings should now be potted into 4-inch pots and placed on a bed of fine sifted ashes quite near the roof glass. A brick pit where gentle fire-heat can be applied in times of sharp frost will suit them very well; but this artificial heat must be avoided as far as possible, as any forcing of the plants into growth now is almost certain to have a detrimental effect on them later in the season. Avoid overcrowding, and ventilate the pit freely as soon as the plants have made new roots. Water with great care, and never until the soil is dry, when a good soaking should be given.

Gloxinias.—The largest of the old tubers should now be shaken out of the soil and placed in shallow pans or boxes. Cover lightly with fine sandy soil, and, when sufficient growth has been made, the tubers may be potted into their flowering pots, which should be quite clean and well crooked.

Seed-Sowing.—Seeds should now be sown of Begonias, Gloxinias, Amaryllis, Clerodendrons, Celosias, Coleus, Grevilleas and Eucalyptus. Fine sifted soil composed of sandy loam and decayed leaves in equal parts should be used. Cover the seeds lightly and protect with sheets of glass in a temperature of 70°.

The Flower Garden.

Seed-Sowing.—Various seeds should be sown now, which include Antirrhinums, Dianthus, Carnations, Pentstemons, Aquilegias and Begonias. All these should be sown in gentle heat, with the exception of Begonias, which should be placed in a temperature of 65°.

Rhododendrons and Azaleas in permanent beds should receive a top-dressing of decayed cow-manure, turfy loam and peat in equal parts before the season is too far advanced. These are surface-rooting plants, and should never be disturbed by forking the soil. The surface may be lightly raked over with an iron rake previous to applying the surface-dressing, which should be made tight by treading while dry.

The Hardy Fruit Garden.

Bush Fruit.—If not already done, the pruning of all bush fruit trees should be finished as soon as possible. Newly planted trees may be cut hard back, in order to shape them for another year. With regard to dessert Gooseberries, the trees should be well thinned out, and, where the spurs are too numerous, every second spur may be removed, in order to admit light and air to the centre of the tree and render the gathering of the fruit less difficult. All side shoots of Red and White Currants may be pruned to two or three buds from the main branch, leaving the leading shoot 8 inches or 9 inches long. Black Currants require a different method of pruning. As most of the fruit is borne on the young wood, let the trees be well thinned by removing as much of the old wood as can be spared, and encourage the strong, young growths from the base, which may be left unpruned.

The Kitchen Garden.

Chicory.—This valuable winter salad is easily forced. The roots may be placed in any dark chamber with a temperature of 60°. If only a small supply is necessary, the roots may be placed close together in 7-inch pots. If watered well when potted, no more moisture will be necessary, and the crop should be ready to cut within three weeks.

Rhubarb Roots may be lifted and put in gentle heat. Any place with a temperature of 50° will answer the purpose. If fresh plantations are necessary for the purpose of producing crowns for forcing, the ground should be trenched and a good dressing of manure given. Plant in rows 5 feet apart and 3 feet in the row.

Horse-Radish.—The present is the best time to make plantations of Horse-radish in deep, rich soil. Trench the ground and give a good dressing of decayed manure.

Royal Gardens, Windsor. JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Rhubarb may now be safely planted, and in doing so see that the ground has received a liberal supply of good farmyard manure. Select the strongest crowns, and allow plenty of room between the rows, finishing by giving the ground a good mulching of stable litter.

Potatoes for Seed.—Go over the Potatoes intended for seed and box the varieties for sprouting. Too much importance cannot be attached to this practice, as it adds materially to the quality and yield. The boxes of tubers should be kept in a cool, airy place where they will be safe from frost. There seem to be conflicting opinions as to whether the seed should be changed each year or not. If one is careful that the seed selected is true to the type and changed to different parts of the garden, I see no reason why seed should not last for a year or two.

Brussels Sprouts.—Where Brussels Sprouts are required for September, either for exhibition or for ordinary kitchen use, a small sowing may now be made in a cutting-box and placed in a cold frame.

Mint.—Several roots of Mint may be lifted and placed in boxes, or planted at the back of a Peach-house border. These will force readily, and will come in handy where Mint sauce is wanted for early lamb.

Peas.—Should any seeds of last season's Peas be left over, they may be sown rather thickly in cutting-boxes and put on the pipes in a warm house. If they have been previously soaked in water for a few hours, the seedlings will come through the soil in about a week. When about

six inches high, they may be cut and used as a vegetable for soup, to which I am told they add a delicious flavour.

The Flower Garden.

Carnations.—If seeds are sown now, plants from these will provide a wonderfully effective display when the ordinary border varieties have passed out of bloom. Many fine strains are now to be had from our leading nurserymen, and if these receive careful attention from the seedling stage, it is surprising what a fine show they will make.

Verbenas.—If Verbenas have not already been sown, no time should be lost in doing so. The variety Miss Willmott is somewhat hard to winter, and many experience great difficulty in getting together the necessary stock. Last season I dispensed with cuttings and grew my entire stock from seed, and I was rewarded by the best display of Verbenas I have seen. Do not sow in much heat, otherwise the plants will become weakly. An ordinary greenhouse temperature will suit them best.

Subtropical Plants.—Where plants such as Solanums, Castor Oil and Wigandias are required as dot plants among the summer-bedding subjects, no time should be lost in sowing the seed. Solanum Pyracanthum is very striking as a dot plant.

Dahlia Tubers may now be gone over and placed in a warm vinery to produce cuttings. This will apply more particularly to the better sorts. The Collarette varieties shown by Messrs. Dobbie of Edinburgh have created quite a sensation among florists, and are likely to be much in demand.

Plants Under Glass.

Primulas.—These will now be growing freely, and ought to be given plenty of room to develop the foliage, which in itself is very decorative. As the pots begin to get filled with roots, occasional applications of liquid manure should be given.

Cinerarias.—The stellata type of Cineraria is undoubtedly a very handsome plant when well grown. Where large specimens are required, they may be potted into 8-inch or 9-inch pots, and as growth advances give plenty of surface feeding.

Ivy-leaved Pelargoniums.—Where large specimens of these popular Geraniums are required for exhibition or decorative purposes, the present is a good time to make a selection of the most suitable plants. These may be pruned and trained, and as growth commences they may be repotted in about the same sized pot and kept growing on.

Chrysanthemums.—Examine cuttings of Chrysanthemums each day, and those that have rooted may be taken out and placed on a shelf near the glass in the same house. The idea should be to keep the cuttings as sturdy as possible and avoid all traces of coddling.

Roses in Pots.—These will be pushing up their flower-buds now, and may be fed with liquid manure from time to time. Ventilating should be done with great care, as the cold air from the outside has a very injurious effect on the young leaves. Somehow or other mildew will make its appearance at this stage, and must be held in check. I have found syringing with Bentley's Mildew Destroyer as good as anything for this purpose.

The Hardy Fruit Garden.

Morello Cherries.—Where a large number of these Cherries are grown, the nailing or tying is a long and tedious job, and as these are usually on a north wall, the work can only be done on fine days. Care should be taken not to overcrowd the shoots or tie them up in threes and fours, as one sometimes sees. When the tying has been completed, it will be well to give the trees a good mulching of farmyard manure.

Recently Planted Fruit Trees.—There seems to be a great diversity of opinion as to whether trees should be pruned the first season or not, and I daresay there is a good deal that might be said on both sides. Personally, I am inclined to think that they are better left alone the first season, as, if hard pruned back, they seem to make such rampant growth, and are not so easily checked afterwards.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

IS THE DAFFODIL A FLORIST'S FLOWER?

"YES" AND "NO."

(Continued from page 63.)

I MUST ask "Somerset" another leading question, or, rather, I must fire off a series of short, jerky interrogations to still further, as I think, drive the nail home. Who are the people who pay the higher prices? What do they do it for? Is it only for the same purpose as a breeder of cattle or a pedigree bull? Where would the market for the hybridist be if it were not for the show people as well? Are not the breeders and the buyers of stock often exhibitors themselves? Then, if a show is thus predicated, must there not be some general agreement about the "points" of a flower? I am glad that "Somerset" puts me down as having a "too catholic sense of beauty" to make a sound florist of the Glenny school, because I think it is true, inasmuch as I fully recognise that the Narcissus family is capable of giving us many and varied types, of each of which I could say, "How happy could I be with either, were the other fair charmer away," only for "either" I would put "any," and I would make "charmer" plural. I even think I have a more catholic mind than "Somerset" himself, for I rank a flower of the Frank Miles type as very bit as worthy of show honours as Homespun, and my favourite Countess of Southesk as White Queen. In writing what I did of Cossack—its round, overlapping perianth and its beautiful deep red eye are just what judges like to see at shows—I rather meant readers to infer that which were not exactly my own sentiments. Even when "Daffodils" was written, I grew weary of red eyes and circular perianths; and had I given my decisions when adjudicating in competitions on my own individual likings or dislikings instead of on what I felt was the united consensus of show people's opinion, I do not think my services would have been requisitioned a second time. Since then, however, a change has taken place, and there is a decided tendency, which I am heartily glad to see, for a taking in of many types in place of just a few. Again I ask: Is not this a stronger reason than ever for the adoption of some fixed canons to guide competitors and judges alike? The only valid argument against this is that there should be no shows at all. Does anyone wish this? A last shot in support of "Yes." After all, is not showing a great pleasure to a large and increasing number of cultivators? Must not they be catered for? The most successful single flower society of the present time is the National Rose Society. It is "miles ahead" of any other. I note how it keeps putting on new shows. First a metropolitan, then a provincial, then an autumn, and now a spring. The Rose community want them and they get them. The exhibitions delight many who are not growers for show. So it is with the daffodil.

Now for some remarks to support the "No" answer to my query. I compare the Daffodil with the Tulip; they have so much in common. In the fifties and sixties I had asked, "Is the tulip a florist's flower?" my reply would have ended with "Yes." There was no garden then, I think about in the same sense that there is now. The by-products of the show were not thought of then. The modern Cottage garden

forms are the basic slag rescued from the great heap of cast-offs. The very fact of having a voracious garden that must be fed no less in spring than in summer has changed the outlook entirely. Tulips in olden days were confined to particular beds and arranged in serried ranks with such minute care that a "cabinet" for summer storage was the necessary adjunct of every Tulipist. I feel fairly certain that they were hardly ever to be seen elsewhere in the ordinary borders. Now, even Mr. Needham grows a few others to brighten up his garden, and in doing this I think he is getting out of the condescending-to-the-popular-taste stage and beginning to really like them. Who knows but what he may be an exhibitor at the May-flowering show at Vincent Square on May 14 next?

In all this my meaning is that with the coming of the garden there has arisen a need for a new type of Tulip—tall, strong and effective in colour, such as we get in the Cottage and Darwins, and, to a lesser extent, in those new redivivus types the Rembrandts and the robust striped generally.

In the case of the Daffodil there has not been the "cast off and lost" stage. Anything now up to show excellence has been at once tried in or for the garden, and so it has come about that the Daffodil has blossomed out as the Rose, and that there is going on now in all large emporiums, as well as in the garden of the amateur, a testing and sorting of which the new Royal Horticultural Society's Rules for Awards, which come into force in 1914, are the outward and visible sign. The Daffodil is not a florist's flower alone. It is a garden flower too. It will grow in beds and borders, in grass and in rockwork, in pots and in boxes for cutting. The family pay us good old-fashioned visits of six months' duration, but it is not a limpet like the Perpetual-flowering Carnation and the Rose. December sees the start and May the finish. I fancy we like it all the better because it is not. Enough has been said to show that we must look after the Daffodil's non-show side. I am one with "Somerset" here, at all events, and I quite grant that many which are not suitable for showing have their uses here, and these, no less than the show varieties, want their Glenny. For instance, I cannot advise the purchase of red eyes which fade after half a day's sun, nor yet such miffy subjects as Lemon Queen, if it is for the garden that they are wanted; while, on the other hand, no praises can be too loud for some of the new Giant Leedsis like The Fawn and H. C. Bowles. The Royal Horticultural Society will be the Glenny here, or shall I say they are going to try to be through their Narcissus committee, who now only want the flowers—with the all-important slip faithfully filled up—to be placed before them, and they will then point out by their awards the purposes for which they are most suited. JOSEPH JACOB.

THE ACTION OF SALT ON SOIL.

SINCE the time of Lord Bacon at least, the advantage or otherwise of salt as a manure has been an unsettled question, except with certain crops, and still more uncertain is the method of its working. It has always been a puzzle to chemists. Its connection with potash is now better known, however, or, rather, the relations of potash and soda. There is no doubt, it would appear from experiment, of the solvent action of the soda in common salt on the soil. The very

complete experiments of Dr. Voelcker in the sixties clearly showed this on a large number of soils; the salt produced plant food in the soil in the shape of various chlorides, including sometimes ammonia, which it liberated from manure, guano and other forms of nitrogen. Seeing that salt has this powerful action, it is probably wise to use it in moderate amounts only, and it must not be looked upon merely as a purifier which can be used without any limit. No less an authority than Sir John Lawes even considered salt detrimental, and we know its effect on weeds when used in excess. It seems likely enough that it is the hydrochloric acid in salt that does the mischief, if this occurs, for chlorides are well known to be injurious to certain crops. This is probably why muriate of potash does not succeed so well as the sulphate; in fact, it seems to injure Potatoes, Sugar Beet and Tobacco, making the first named waxy, preventing the ready crystallisation of sugar in Beet, and in Tobacco impairing the quality.

Salt has the property, like other saline solutions, of clearing muddy water, and so it may be useful in clay in preventing the puddling action which nitrate of soda causes. It has other effects, sometimes questionable or harmful, and so it should be used with caution, especially as large quantities seem to be less favourable than small ones.

GERVAISE TURNBULL.

THE WALNUTS AND THEIR CULTIVATION.

THE Walnuts, or species of Juglans, are an important group of trees, for, in addition to producing valuable timber, the fruits of most kinds are edible, while all the species form ornamental trees with distinct and decorative foliage. They are credited with being rather tender, but this only applies to young, fast-grown trees and to premature growth in spring. After a mild winter young shoots are formed earlier than usual, and they sometimes fall a prey to late frosts. So far as winter frost is concerned, they are quite hardy, and well-developed specimens of the common Walnut are found as far North as Aberdeen. As a rule, those growing in the South of England fruit more satisfactorily than those in other districts, trees growing in the North only perfecting fruits occasionally.

The Walnuts require good, deep, loamy soil, such as may be expected to produce good Oaks. As a rule, they are planted as ornamental trees in parks and gardens, rather than to form woods or plantations, but there appears to be little reason why one or two species should not be used by the forester in the South of England. The timber is always valuable, while that which is specially well figured commands a fancy price. A very small quantity of timber is cut in this country, and the bulk of that required by manufacturers is obtained from France, Italy, Asia Minor and North America. That from the first three countries named is the wood of the common Walnut (*Juglans regia*), and that from North America is the Black Walnut (*J. nigra*). It is used largely by cabinet and furniture manufacturers, and is one of the most popular woods for the manufacture of gun-stocks. The fruits of the common Walnut are in demand in European countries for dessert, and the fruits of other species are used in their respective countries for the same purpose. An

oil is also obtained from the kernels of Walnuts, which is used in food preparations and paints, according to the method of extraction, that produced by cool extraction being favoured for the former, and that expressed by heat for the latter purpose.

All the species are propagated by seeds and the varieties by grafting. When seeds can be planted in the positions the trees are to occupy, growth is, as a rule, more satisfactory than when the young trees have to be transplanted. When grown in nurseries they must be transplanted frequently, otherwise long roots will be produced at the expense of fibrous roots.

Although there are comparatively few species of Juglans, they are widely distributed, for they are found from Eastern Europe through Persia and Asia Minor to the Himalaya, China and Japan, while there are also representatives in North America. In addition to the species, there are several varieties of the common Walnut, and also a number of hybrids, which claim *J. regia* for one parent.

Juglans regia, the best known member of the family, is found from Greece through a considerable part of South-Eastern Europe to Persia, Asia Minor and the Himalaya, while a form is also present in China. When growing under exceptionally favourable conditions it attains a height of from 80 feet to 100 feet, with a trunk upwards of 15 feet in girth, but it is more frequently met with between 50 feet and 80 feet in height. It is easily recognised by reason of the silvery bark of the younger wood and by its pinnate, glabrous leaves. In other species the leaves are clothed with soft hairs. The leaves are usually from 8 inches to 10 inches long, and are composed of from five to nine elliptical or ovate leaflets. The male flowers are in catkins from 2 inches to 5 inches in length, and the female flowers appear in small clusters. It is grown in this country for ornament and fruit. Large numbers of trees are grown in France, Germany and Switzerland for the sake of the fruit. Some trees form large burrs on the trunks, and the wood from them is usually beautifully marked. It is cut into veneer and used for the better qualities of furniture. Several well-marked varieties have been given varietal names. Distinct ones are *J. laciniata*, with finely divided leaves; *J. maxima*, with large fruits; *J. monophylla*, in which the leaves may consist of one, two or three lobes; *J. præparturiens*, a form which originated in France and is remarkable on account of its coming into fruit at a very early age; *J. heterophylla*, with leaves of various shapes, sometimes almost normal and at others having the leaflets almost as finely divided as in *J. laciniata*; and *J. serotina*, said to be a Chinese form, which commences to grow somewhat later than the type.

J. nigra is an important North American species which, under the most satisfactory conditions, grows 150 feet high, with a girth of 15 feet or 20 feet. Numerous trees in the South of England approach or exceed 100 feet in height, with a girth of from 9 feet to 12 feet. Its timber is of a rich dark brown or blackish colour, and is much appreciated by furniture-makers. The leaves are handsome, up to 3 feet long on vigorous trees, and composed of from fifteen to twenty-three leaflets. The globular fruits have very thick shells and small kernels. This species is worth planting under forest conditions in the South of England. It is commonly called the Black Walnut.

J. cinerea.—This is the Butternut of the United States. Forming a handsome tree from 50 feet

to 100 feet in height, it produces long, pinnate leaves, made up of from eleven to seventeen oblong, hairy leaflets, and bears its fruits in clusters of from three to five. The nuts are oblong, $1\frac{1}{2}$ inches to $2\frac{1}{2}$ inches long, and the shells are deeply furrowed. The kernels are pleasantly flavoured and large. There are very few large trees in this country, one of the best being recorded as growing in the grounds of Mr. C. S. Dickens at Coolhurst, near Horsham. This exceeds 50 feet in height.

J. cordiformis is a Japanese species, notable for its fine foliage and long racemes of male flowers. It forms a tree 50 feet high and produces leaves between 2 feet and 3 feet in length, made up of from eleven to thirteen broadly oblong leaflets. The male flowers are green, and produced in drooping catkins 1 foot or more long. The female flowers are also borne in long catkins, and from four to six fruits may sometimes be seen on a single stalk. These fruits are heart-shaped and about an inch wide. The kernels are fairly large and pleasantly flavoured.

J. mandshurica is a somewhat similar tree to the last named, but is a native of Amurland. It commences to grow early and is often injured by frost.

J. pyriformis and **J. vilmoriniana** are hybrids between *J. regia* and *J. nigra*, combining the characters of both species; and *J. alata* is a hybrid between *J. cinerea* and *J. regia*, its distinguishing features being intermediate between the two.

Other species which may be obtained are *J. californica*, *J. sieboldiana* and *J. rupestris*. D.

BOOKS.

Colour Standards and Nomenclature.*—This is the title of a very wonderful book, produced after much labour and expense by Mr. Robert Ridgway, the Curator of the Division of Birds in the United States National Museum. In the preface the author bemoans the lack of a colour standardisation, mainly, I take it, because it would be so exceedingly useful to ornithologists and other naturalists. He calls attention to the fact that he made an attempt more than twenty years ago to remedy the deficiency by publishing a book containing 186 samples of named colours. Naturally, these were found to be not nearly enough to be of any great use, so Mr. Ridgway set to work to enlarge and improve upon it. The result is the present edition of "Colour Standards and Nomenclature," containing no fewer than 1,115 distinct shades of colour, each one in its proper place according to the ideal chromatic scale which he has adopted after, as it were, making the solar spectrum "loop the loop." The means by which he has arrived at all the different shades portrayed from the six fundamental colours of red, orange, yellow, green, blue, and violet occupies the first part of the most instructive prologue. This in turn is followed by discussions on "Colour Names" and "Colour Terms." In the first of these we have the pros and cons for the adoption of a recognised standard, not only of colour, but of colour names, and I think the author has very little difficulty in showing that the one is as necessary as the other. It is of no use to have a purple colour standard unless everyone agrees to put into the background his own preconceived idea of what purple is, and eliminating the personal equation

* "Colour Standards and Nomenclature," by Robert Ridgway. Eleven hundred and fifteen named colours; fifty-three coloured plates; 8vo., cloth; 1913; price £1 15s. English agents: Wesley and Son, 28, Essex Street, Strand.

altogether, to adopt that of the standard. The latter part is taken up with definitions of "colour terms." Here, again, when we speak or write of "pale colour," "broken colour," "hue," "tint," "shade," "tone," &c., we must all mean exactly the same thing by these expressions or words, or we shall be at cross purposes and be but little "farrarder." The remaining pages contain technical tables on the composition of colours. Twenty-four shades are so arranged that they are easily referred to. I am only just beginning to make any practical use of it, but my first impressions are decidedly favourable. It is very handy, much more so than the Colour Chart (*Le Répertoire des Couleurs*), which I have always found rather clumsy to handle. It contains about the same number of shades as the older work; while its names, such as endive blue, vetiver green and xanthine orange, although they sound strange and unfamiliar, are no more so than those of the Chart, and, like them, they can be referred to by number. I expect it will be found easier to match the colour of the object with that in the book if a piece of white cardboard, with a small space cut out to exactly fit the oblong on the page, is used. By this means much more exact correspondence will be obtained between the one and the other, for necessarily, as the work is only in octavo size, the shades are somewhat close together. I am looking forward to the time when I can call it an old friend. I may be mistaken, but somehow or another I feel this is what it is going to be.—JOSEPH JACOB.

Albury Park Trees and Shrubs.*—About three years ago a catalogue of the trees and shrubs of Syon House Gardens was favourably reviewed in these columns. The book under review forms a companion to the Syon House list. It is compiled by the same author and has been undertaken at the request of the Duke of Northumberland, the owner of both the Syon House and Albury estates. Reference to Albury is frequent in horticultural literature, and the publication of a complete list of the trees and shrubs of the estate forms very interesting reading. The following are selected from among the most remarkable of the trees recorded: *Tilia argentea* or White Lime, a magnificent specimen with remarkably erect branches, 109 feet in height, girth 16 feet; the lower branches have a spread of 88 feet, and it is claimed to be the finest example in cultivation. *Populus serotina* or Black Italian Poplar; this tree is found to be not less than 150 feet, which is almost a record height for any tree in this country. *Cedrus Libani* or Lebanon Cedar; the tallest at Albury is 127 feet high by 15 feet in girth. Three trees in a fine group on the lawn north of the house are said to be among the tallest Cedars in cultivation. *Sequoia gigantea* or Wellingtonia; the finest specimen at Albury has attained a height of 97 feet, by 8 feet 10 inches in girth. This must be one of the tallest Wellingtonias in cultivation. The Yew hedge at Albury is believed to have been planted about 1676 under John Evelyn's direction; it is 448 yards in length with a gap of 90 feet. It contains about two hundred trees and the stumps or a number of those which have died. We have nothing but praise for the admirable and careful way in which this work has been prepared, and we hope the day is not far distant when lists on similar lines will be issued from other noted gardens and estates throughout the country.

THE GARDEN.

No. 2204.—VOL. LXXVIII.

FEBRUARY 14, 1914.

NOTES OF THE WEEK.

Editorial Notices.—In this and subsequent issues editorial notices will be found immediately preceding "Answers to Correspondents." This will enable us, at the request of a large number of readers, to devote more space to "Notes of the Week."

An Annual for Present Sowing.—The beautiful old-fashioned annual named *Salpiglossis* is again becoming a favourite for summer bedding, and as the new shades are so fine, they are worth a little extra trouble in growing. As a rule, they are not sown early enough, at least in cold districts. Seed may now be sown in a cool house or frame, and an endeavour should be made to have good, sturdy plants for putting out in May.

Propagating Delphiniums.—It is not too late to increase the stock of named varieties of Delphiniums. If young shoots are taken from the base of old plants which are starting into growth, placed in small pots of sandy soil and grown in a cold frame, they will form nice young plants for planting in April. By this means a succession of flowers will be obtained. The soil for these plants should be of a rich nature.

An Interesting Rock Plant.—*Erigeron mucronatus*, with its small, Daisy-like flowers, should find a place in every rock garden. It is a Mexican species of prostrate habit, and it flowers continuously from June till September. When first open the flowers are pink, afterwards changing to white, and as the flowers are continually opening, both colours are usually to be seen on the same stem. This *Erigeron*, which is synonymous with *Vittadenia triloba*, is seen to the best advantage when grown on a protected shelf in the rock garden and allowed to overhang large boulders. It is of perennial duration and may be raised from seed.

The Sweet Pea Annual.—This, the official organ of the National Sweet Pea Society, has just been published, and, as usual, contains a great deal of information that must be of considerable value to those who love and grow these flowers. We are pleased to find it much better illustrated than last year's "Annual," and the answers to the six questions sent out to members by the committee will provide much food for reflection. We wish an analysis of the first four of these answers had been included, as was done last year. The articles on Sweet Peas in Japan and early-flowering Peas in New Zealand prove that the cult of the flower is extending to many

parts of the world. A copy has been sent to every member of the society. Non-members wishing to obtain it can do so from the secretary, Mr. H. D. Tigwell, Greenford, Middlesex, post free, 2s.

Alpines Under Glass.—Visitors to Kew during the next month or two should make a point of visiting the Alpine House, a modest little structure that nestles away in a corner of the herbaceous grounds. Already it is gay with such Crocuses

Ferns. The russet brown fronds of the latter, with the dead leaves of the trees that have nestled among them, make a charming foil for the glistening white Snowdrops, and it is in such situations as these that their beauty remains unsullied for a long time. In some places the little purple-flowered hardy Cyclamen Coum is added to the Snowdrops, with excellent results.

A Good Early Yellow Crocus.—One of the best Crocuses that are flowering in the open garden just now is *C. chrysanthus*, a brilliant yellow flower that makes a delightful patch of colour in the winter sun. Although it is not quite so sturdy as the yellow Dutch Crocus, the yellow hue is quite as good, and on account of its early flowering should be more widely grown. There is a good variety of it named *fusco-tinctus*, the outside of the petals being slightly tinted with a sort of brown shade.

An Ancient Royal Fern.—An interesting specimen of the Royal Fern (*Osmunda regalis*) may be seen in the Rock Garden at Kew. It was presented to Kew by the Director of the Imperial Botanic Garden, St. Petersburg, and is one of several which were originally obtained from near Adler in the Caucasus, on the shores of the Black Sea. Estimated to be over a thousand years old, the plant has a large, woody rootstock, with a circumference of 5 feet at the base. It is about 2 feet 6 inches high, and has formed eight distinct stems, with ten separate crowns, having a diameter over three feet. An account of this plant is given in the *Kew Bulletin*, 1913, page 359.

Wart Disease of Potatoes.—Stringent regulations for preventing the spread of this disease of Potatoes have just been issued by the Board of Agriculture and Fisheries. Potatoes are not to be planted in infected areas without a licence granted by an inspector of the Board, and such licence may prescribe the varieties authorised to be planted. A licence is also necessary for the removal of Potatoes that have been grown in an infected area. Notification of the disease

ERIGERON MUCRONATUS OVERHANGING LARGE BOULDERS IN THE WISLEY ROCK GARDEN.

as Sieberi, chrysanthus A. E. Bowles and biflorus; Irises reticulata, Danfordiae and Tauri; Cyclamen ibericum, and some of the earlier Saxifrages. In a week or two there will be a great many more flowers of interest, and, owing to the shelter, these can be studied in comfort.

Snowdrops and Hardy Ferns.—A particularly pleasing picture in the woodland just now may be found where hardy Ferns are grown beneath lofty trees, and Snowdrops planted between the

must be given by the grower to the Board, or some person authorised by the Board to receive such notice, and an inspector may, by notice served upon the occupier of any premises within an infected area, require him to lift any Potatoes suspected of being diseased. Those who grow Potatoes should at once write to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W., for copies of the Orders relating to wart disease.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Antirrhinums as Bedding Plants.—I was pleased to see Mr. E. Harriss's letter, page 42, issue January 24, in which he recommends the above plants as bedding subjects. The intermediate section is the best for general purposes, but the tall-growing one is equally good for grouping in borders that are wide enough. Nearly twenty years ago I grew Antirrhinums in a long border in front of a plant stove. The soil in this border was rich, and the plants formed very fine specimens, the foliage, as well as the flowers, being handsome. — G. G

Cistus corbariensis.—The note and accompanying illustration of this charming Rock Rose which appeared in the issue of THE GARDEN for January 31 would, no doubt, be interesting to many readers who take a delight in rock gardening. *C. corbariensis* is by far the best of all the family for growing in the rockery, being dwarfer and more diffuse in growth than any of the others in general cultivation. Regarding *C. laurifolius*, the writer of the note says it "does quite well even in Scottish gardens," evidently inferring that this is the only variety suitable for growing so far North. This, however, is not the case, as we have grown several varieties quite successfully as far north as Perthshire, where they withstood our ordinary winters with impunity, although they did succumb to one of extra severity. Varieties which grew well and flowered profusely were the one under notice, *corbariensis*, *florentinus* (both of which undoubtedly have a good deal of *salviaefolius* blood in them), *ladaniferus*, *salviaefolius* and *laurifolius*. The latter is exceedingly floriferous, and also ripens its seeds plentifully. Last autumn we saved seeds of this variety, which were sown a fortnight ago in heat, and they have already germinated. Rock Roses are liable to be damaged by heavy falls of snow, the branches breaking off very readily when they are pressed downwards; consequently, it is a good plan to support them on the approach of winter, so as to avoid damage from this cause.—W. L., *South Ayrshire*.

Primula pulverulenta Mrs. R. V. Berkeley.—The notes on this beautiful Primula by Dr. Macwatt and "A. D. M." in your issues of January 10, 24 and 31, both refer to the facts that it was raised from seed "sent home by Messrs. James Veitch and Sons' collector from China," and that it "has not produced seed in this country." But as they both stop at that point, it may have been overlooked that the variety Mrs. R. V. Berkeley is not unique, and failed to get an award at the International Show at Chelsea because an identical albino form had been shown in 1911. On June 6 of that year Mr. Lawrence Johnston showed two very fine forms of *pulverulenta* which he had raised from seed. One was the white form

with orange eye, the other was a very soft pink form, and, under the impression that intermediate shades of colour would follow, the individual names that had been given to the two varieties were dropped, and they were unanimously given the award of merit under the name of the Hidcote strain. They failed to pass into commerce, however, and seem to have been overlooked; but we understand that they proved good seed-bearers, and that the progeny to a large extent bred true, which is the important point. Last year an albino *pulverulenta* identical with Mrs. R. V. Berkeley turned up in a batch of seedlings in an East Coast garden and also proved fertile. There is little doubt that seed is the only satisfactory method of propagating these short-lived Primulas,

AN AVENUE OF ANCIENT YEWS IN THE GARDENS AT COPPED HALL, ESSEX.

and is essential if the variety is to become popular.—R. W. WALLACE.

Yews and Churchyards.—Will you please give me, through the medium of THE GARDEN, the reasons why Yew trees are so frequently grown in churchyards? Thanking you in anticipation,—M. H., *Coventry*. [The wood of the Yew, although very hard, is also flexible and elastic. In olden times it was in great request for the making of bows, and for this reason it was planted in churchyards, where, we may assume, the inhabitants were free to cut their own bows. But it was not only in churchyards that Yews were planted. At Albury Park, Surrey, there remains an old Yew hedge 10 feet high and a quarter of a mile long. At Copped Hall in Essex, "at one time a mansion of pleasure and privacy for the Abbots of Waltham," is a

famous Yew avenue which we illustrate on this page. At the Palace, Hadham, Hertfordshire, which once belonged to the Bishop of London, there stands a Yew hedge 3 yards thick; and at Bishopsbourne, near Canterbury, there are Yew hedges about 14 feet high and 10 feet thick. While the Yew is now a feature of many Old English gardens, in former times men loved it with a certain reverence for the service it rendered them. Thus appropriately does Conan Doyle, in his "Song of the Bow," speak of its making:

"Of true wood, of Yew wood,
The wood of English bows;
So men who are free
Love the old Yew tree,
And the land where the Yew tree grows."—ED.]

Canker in Fruit Trees.—

"Scientist," page 56, gives an exhaustive account of the cause of canker in fruit trees from his point of view, and would have us believe that all canker is caused by the fungus coming in contact with wounds in the bark. This is an assertion that I do not agree with, and for reasons which I will endeavour to show. In some gardens the soil is a stiff loam on the surface and the subsoil is of a heavy character, not quite clay, but a near approach to it, and consequently of a cold nature, and in its natural condition very impervious to a free percolation of water from heavy rains. Where the surface soil is, say, from 1 foot to 2 feet deep, and of a free-rooting medium, when well dug and constantly manured, but with the subsoil left in its natural condition, this leaves a hard, pan-like substance below, causing a lodgment for superfluous water, from which it cannot drain away rapidly. Such a combination of uncongenial circumstances is one of the main causes of canker. Now, trees so planted will develop much canker in certain varieties—as Lord Suffield, Potts' Seedling, Cox's Orange and Warner's King. Trees planted in the autumn quite free from any wound whatsoever—in fact, never pruned at that period—will develop canker the following autumn. Such an instance as this does not bear out "Scientist's" views. Some of the worst cankered

trees in soil of this description—those of Cox's Orange Pippin—if taken up, planted afresh with the roots much nearer the surface and in a compost of a lighter character, will grow away afterwards, feeling none the worse for their previous cankered state. If varieties were chosen that are not liable to canker in unsuitable soil, we should not hear so much complaint about it. How is it we seldom hear of canker on Bramley's Seedling or Worcester Pearmain growing next to affected trees and receiving the same treatment in pruning, and that sometimes pretty rough when the land between the trees is cropped with vegetables and horse labour is employed? Under such conditions trees do receive wounds in the bark. Writers with purely scientific knowledge of tree growth do not consider the requirements of the roots under exceptional circumstances.—E. M

The Daffodil in New Zealand.—It may interest your correspondent "F. H. C.," whose remarks appear in your columns of November 1, 1913, page 547, to know that New Zealand-raised seedlings occupied a much more prominent place in the Auckland Daffodil Show than appears in the newspaper cutting from which he quotes. In the champion vase class for forty varieties, the winner staged twenty-seven seedling varieties of his own raising, and won with points to spare from two other strong exhibits. In the single bloom open class, four out of the eight classes were won with local-raised seedlings, and in one other class a local-raised seedling gained second place. Two very fine seedlings were also shown in the seedling classes. The Auckland daffodilists are very keen, and keep well up to date with new varieties, so that the honours obtained were won in good company. Whether this justifies the assertion "sic transit Gloria Mundi" I leave to "F. H. C."—THE JUDGE AT THE AUCKLAND DAFFODIL SHOW.

Colour Effects with Annuals.—As mentioned by your esteemed contributor Mr. R. P. Brotherton on page 30, issue January 17, the coloured illustration of annuals accompanying THE GARDEN for January 3, together with notes relating thereto, raises several interesting points concerning colour combinations. The arrangement of colours is a matter for the display of individual taste to such an extent that it would be invidious to lay down any hard-and-fast rules with regard to it; but, at the same time, it is well to bear in mind that certain glaring contrasts should be avoided if the best possible results are to be obtained. In the above-mentioned coloured plate the sharply defined belts of brilliant blue, white and rosy carmine are, I venture to think, in vivid contrast rather than harmonious blending. May I suggest a colour-scheme to be worked out from one end of the border to the other, rather than across it? By beginning at one end with white and cream flowers and following with yellow and orange to deep scarlet, a return could be made in reverse order to cream and white. Blue flowers could then be used, beginning with the palest shades and gradually deepening the tones until purple is reached, again reverting gradually to white. Then pinks could be introduced, the deeper rose shades following the paler tones, until crimson is arrived at. Then, again, by gradations of colour in reverse order, white could be reached. In all cases I would suggest that the palest shades be used near the front of the border. The diagram will explain the notes.

SWEET PEA STREAK AND OTHER DISEASES.

THERE seems but little doubt that some confusion has arisen with regard to the diseases from which Sweet Peas suffer. Until a few years ago mildew was the only fungus attack which Sweet Pea growers feared to any great extent, but with the advent of the wavy standard forms more attention began to be given to this always popular flower. More care was lavished upon it individually, more was expected of the individual, and more note was taken of a single death here and there.

Streak.—Then we began to hear of streak. Sometimes a brown streak appeared in the stem, but in almost all cases of the disease the upper parts of the plants began to turn yellow, the leaves to become spotted, and a curious curled appearance of the upper part of the stem and the flower-buds appeared. Attacked plants usually died more or less rapidly, and sometimes looked wilted for a time before they died outright. It seems clear now that more than one disease has been included under the term "streak."

A very large number of plants said to be affected by streak reached the present writer, and as a result of his examination of them and subsequent experimental infection of plants, he came to the conclusion that the large majority of these cases of disease were due to the attack of a fungus called *Thielavia basicola* upon the roots. It was often very difficult to make out the gross symptoms of the disease affecting the plants from the specimens sent, as they had often been out of the ground for several days and were frequently badly packed; but it is certain that not all of them showed the brown streak in the stem which is characteristic of the true streak disease. Mr. Massee, who also examined a very large number of plants, also came to the conclusion quite independently that we had to deal with a root disease.

A Root Disease.—The symptoms present in the root were the darkening of a less or greater length of the root surface, and sometimes also of the base of the stem, owing to the presence of the dark chestnut-coloured spores of the fungus upon the root or stem base and the death of the parts attacked. This dark part never extended far up the stem. The death and rotting of portions of the root adversely affected the stems and leaves owing to the check imposed upon the collection of water and its supply to the foliage, and many of the symptoms outlined above followed as a natural consequence of this check.

Checks to Growth.—The present writer gave an account of his experiments with the fungus on the Sweet Pea in the Journal of the Royal Horticultural Society, and showed that the attack of the fungus upon the root produced the root-rot, and, after causing the shrivelling and yellowing of parts of the stem remote from the point of attack, brought about the death of the plant. The most significant thing arising from these experiments was, however, the difficulty experienced in causing the fungus to attack the root when growing under healthy conditions; but when a check was imposed upon its healthy development, the root was speedily attacked and the plant succumbed, whereas where the root was similarly checked and there was no fungus, the plants recovered without exception. It seems, therefore, that a check to the root may lay the plants open

to attack, and as the fungus is widely distributed over the country in the soil, the attack is very likely to follow. Probably any check will be an efficient preparer of the plant for attack, and one cannot help thinking that the methods often adopted, with the very best intentions, in preparing the soil for Sweet Peas lay them open to the attack. Instead of intimately mixing manure with the soil, it is too often placed in layers—a layer of soil and a layer of manure, and so on. Too much manure is used. A trench is dug which acts as a trap, into which water runs from other parts of the soil as into a drain, and, quite likely, as into a drain without sufficient fall. Watering is indulged in too frequently or injudiciously, and so on.

Preventive Measures.—It seems evident that if one could sterilise the soil effectively, the fungus would not prove troublesome; but the difficulties of doing this outdoors are at present insuperable, and no kind of chemical treatment has, so far, proved really effective. All that can be done at present is to cultivate the plants rationally, not to over-stimulate or grow them in an acid soil, to see that supplies of potash and phosphates are ample, and to take great care as to the fashion in which watering (if any) is carried out. We ought not to mix up these diseases, now we know we have more than one to deal with, and perhaps the best name to give this would be Sweet Pea root-rot. It is without doubt very widely spread in this country.

Another Disease.—Much more rarely we find another fungus, a species of *Fusarium*, attacking the roots of the Sweet Pea and bringing about a withering of the plant. We may call this wilt disease. The fungus grows up into the stem and stuffs up the vessels along which the water flows, so that the supply is cut off from the leaves. It is similar in its action and in its origin to the sleepy disease of Tomatoes, and, if it occurs, the plants attacked should be uprooted and burned, and the plot where it occurred avoided for some years for Sweet Pea cultivation.

The True Streak.—Much more recently it has been discovered by Miss Cayley that the water-soaked areas in stem (forming streaks) and leaves, which are characteristic of some cases of disease, are due to the attack of certain bacteria, and it is, since this attack is apparently always characterised by streaky areas in the stem, to this form of disease that the term "streak" should be restricted. Comparatively little is known about this disease, but the bacilli appear to live in the spaces between the cells and to pass from place to place through these spaces. They seem to develop rapidly only after a period of hot weather, and may exist in the plant without betraying their presence, ready to spread as soon as conditions are favourable. Unfortunately, they may exist in the seeds, and, at any rate at times, show their presence by brown areas inside the cotyledons of the seed, spreading thence through the plant. Whether they also get into the plant from the soil, as is probable, or are carried from plant to plant by such insects as aphides or pests as eelworms, as is possible, is not yet fully proved. In any case it is difficult to see how such an insidious attack can be avoided, though it is just possible, but not entirely certain, that rigid elimination of diseased plants from the seed stocks and prompt burning of all diseased plants in the areas cultivated would do something to check the trouble.

F. J. CHITTENDEN

PRACTICAL HINTS ON GROWING SWEET PEAS.

WITH the lengthening days the work among the Sweet Peas will commence. Certainly the grower who raises plants under glass, whether it is in the autumn or the spring, will have the seed

sown; but thus far the seedlings will not have occupied a great deal of time. The autumn-sown plants are now growing freely, and young growths should be pushing from the base of the plants. The present time is a very suitable one to handle the plants, and it will be quite wise to put a few small twigs, preferably of fine Birch, to keep them more or less erect. This is not absolutely necessary, but it prevents the young growths becoming entangled with their neighbours, and certainly keeps them sturdier by allowing the free circulation of light and air between the plants. The soil in which plants were sown singly in pots in the autumn, or potted off singly soon after germination, after two or three months in a cold frame is apt to become rather green on the surface, and, during the operation of twigging, the green should be removed; this will keep the soil sweeter and tend to better root action. An occasional spraying overhead on fine days with a very weak solution of permanganate of potash will be beneficial, and I would certainly suggest that such treatment be continued, even after the plants are put out in the ground. It is needless, perhaps, to add that too much air cannot be given at this season, for it must be borne in mind that very few weeks will elapse before it is necessary to plant out, and they cannot be in too hard a condition to withstand the cold winds that are often experienced soon after planting. These winds are, I think, more harmful than a few degrees of frost.

Spring-Sown Plants should be coming through the soil nicely. They should have had slight warmth during the period of germination, but, after the first pair of leaves have unfolded, the process of hardening off must be commenced, or the young plants will soon become attenuated.

The grower's aim should be to keep them stiff enough to stand quite upright until planting-out-time.

Sweet Peas Under Glass.—Plants that are being cultivated for blooming under glass should now be in their flowering pots or planted in the borders, whichever system is being adopted. Great progress has been made in this phase of cultivation during the past year or two, and results obtained which even five or six years ago seemed well-nigh impossible. But such results are only

moisture at the roots and in the air will be beneficial. Where a good number of plants are grown under glass, the question of training them crops up, and though I have seen several different systems tried, including ordinary stakes, Bamboos and various string arrangements, I doubt if there is anything so good and easily fixed as the Simplicitas Netting, this being even more effective indoors than in the open. It is too late to speak of varieties for cultivating under glass this season, and except

for exhibition very few varieties are required; but it may not be out of place to mention a few that I think will be greatly in demand for this purpose for 1915. Dobbie's Frilled Pink, quite an acquisition; Thomas Stevenson, considered the finest variety under glass; Double Maggie Stark, a nice soft orange pink; and Dobbie's Lavender G. Herbert and R. F. Felton, both grand varieties in this colour. Robert Sydenham, though little has been seen of this up to now, before the end of the season, if I am not greatly mistaken, will have established a reputation second only to my namesake. Margaret Atlee I have not seen under glass, but I feel sure this will be quite good enough in the deeper cream pinks, while Lady Miller cannot fail to be in demand as a pale cream or salmon pink. White is always in demand, and Florence Wright Spencer will be difficult to beat, the extra substance in the bloom making it a desirable variety.

Preparation of the Soil.—Turning to the preparation of the soil out of doors, one naturally infers that it has all been well cultivated before this, and those who have not given their ground a dressing of lime on the surface may with advantage do so some time before this month is out. Not only will it benefit the soil—if heavy by its mechanical action—but it will tend to free it of slugs, wireworm and other pests which in the early stages

do much harm to the plants. Ground that is known to be badly infested with wireworm may be partially cleared of this pest by burying Potatoes or Carrots in the ground and examining them every second or third day; this for preference before the plants are put out. To facilitate matters at planting-out-time, short, bushy stakes should be prepared during bad weather and tied up in bundles ready for use, as all plants should be staked

SWEET PEA MRS. HUGH DICKSON, A BEAUTIFUL CREAM PINK VARIETY SUITABLE FOR EXHIBITION AND GARDEN PURPOSES.

obtained by very careful cultivation, and one of the chief essentials is to keep the plants growing very steadily at this season. Great care is necessary in watering, and once they have been well watered in after potting or planting out, very little more will be needed for some time; but as the days lengthen and the temperature of the house is raised by sun-heat, both root and top growth will be very rapid, and, naturally, a little more

immediately they are planted. If left lying on the ground only one night, it is just possible that some may get eaten by slugs. Where they are grown naturally for cutting purposes, there is nothing better than good, long Hazel stakes, and as these are eagerly snapped up nearer staking-time, it is wise to order them beforehand and get them pointed ready, the same remark applying to posts, &c., where the cordon system of training is to be adopted.

Sowing Seeds in the Open.—There are still a good many lovers of the flower who have neither the time nor the convenience for raising their plants under glass, and must perforce sow them in the open ground. The date of sowing must, naturally, differ according to the locality and the nature of the soil; but to get the flowers reasonably early, sowing should not be delayed longer than can be helped. On light soil the seeds may be put in almost at once, but on heavy loams it might be wise to defer it till the first week in March. An inch to 2 inches in depth is sufficiently deep to make the drills, and two narrow drills are preferable to a wider one; but, whichever system is adopted, more seeds must be sown than will be needed as plants, thinning them out later to a few inches apart.

THOMAS STEVENSON.

SWEET PEAS IN LARGE POTS.

When Garden Space is Limited.

—What a convenience an adjustable garden would be! When plants are plentiful, just to turn a screw and it is larger; or, when something has gone wrong, to give a twist the other way, and lo! it is smaller. For several seasons now, when Sweet Pea sowing-time has come round, I have wished for a garden a size or two larger. The naughty Daffodils and Tulips never leave a square foot of ground for anything else, and I must have my Sweet Peas. Luckily for me, I had some two dozen large pots from 10 inches to 12 inches in diameter, which it struck me might be the means of solving the difficulty. Four years ago these were requisitioned, and the result has ever since been most successful from a cutting-for-the-house point of view.

I raise seedlings in cold frames in 3-inch pots, and in due course, when they are about six inches to eight inches high, I transfer them to these large pots, which are then placed in a row alongside a convenient wall, about a foot or rather less away from it. Hence they are trained in the usual manner on sticks, which are made firm by being attached to a couple of wires (one higher and one lower) stretched between two iron (in my case, but wooden ones would do as well) posts, fixed permanently at the ends. They do not get much food, for my object is to induce short, sturdy growth, so as to be able to cut the whole top of some of the flowering shoots to furnish my vases with greenery.

Everyone to his fancy in Sweet Pea arrangement, as in other things. Personally, I think

most arrangements have not half enough foliage about them, and that nothing excels the plant's own leaves for the purpose. I find in the early weeks of blooming quite sufficient longish-stemmed flowers to fill up, if there is too much green. As the season advances this does not seem necessary, for I use lower, wider and shallower receptacles, which suit the more bushy tops.

The idea of pots may be utilised for other purposes besides cutting. The whole row may be left to bloom, when it is capable of giving a fine three weeks' show; or individual pots may be used for vacant spaces in borders by being plunged in the soil. Necessity is the mother of invention. It is enough for me to suggest, as I have done, the utility of pots.

Sweet Peas and Tulips.—In conundrum form it would be, "Why are Sweet Peas like Tulips?" The stock answer, "Because there is a 'p' in both," is quite true; but it is too

A COLONY OF THE BEAUTIFUL SAXIFRAGA BURSERIANA GLORIA.

parochial and too "catchy." There is a real reason. Both plants have for different reasons been very useful to the botanist. No one will ever forget the part the Sweet Pea has played in Mendelian development. True, the abbot himself used only the culinary Pea, but one has only to turn to such a book as R. C. Punnett's "Mendelism" (Plate IV.) to see how in subsequent investigations the Sweet Pea itself has been used. In a similar way the Tulip was used in the eighteenth century. It is easy to see how its large and simple-shaped flower made certain observations comparatively easy and possible. As a definite instance I would cite a small book by John Hill, M.D. (1758), entitled "Method of Producing Double Flowers from Single by a Regular Course of Culture." Here the Tulip is the flower chosen, on account, as the author says, of its size and simplicity.

JOSEPH JACOB

A BEAUTIFUL SAXIFRAGE.

SAXIFRAGA BURSERIANA GLORIA.

THE first of the Cushion Saxifrages which brighten my garden in the earliest dawn of spring is *S. burseriana*; in fact, long before the official date which separates spring from winter.

Usually the first week in January sees the blossom points in the close, greyish green, hedgehog-like tuft begin to swell, and if we are favoured with a reasonable amount of bright light, these buds rapidly develop, taking on a bright red hue. Should the conditions of our variable climate then be less favourable (as they not infrequently are), it is surprising how long the embryo flowers will so remain. If, however, as this year, the weather is bright and the temperature moderate, the buds push out upon stalks

some 1½ inches long and then open, displaying beautiful, pearly white flowers of a satin-like texture daintily crimped at the edges. The stalks which support these lovely flowers are of the rich red colour which characterises the buds, the whole making a most attractive picture in our alpine garden so early in the year. If the elements are kind, or if a roof glass is arranged above the tuft so as to protect the flowers from heavy rain, it is surprising how long they will remain in good condition, despite their delicate and fragile appearance. The comparatively recent form known as *Gloria* has flowers considerably larger than the type, while the foliage also appears to be more sturdy. The accompanying illustration of a very fine group grown and staged by Mr. Clarence Elliott exhibits the attractive appearance of a colony of this Saxifrage, and also indicates how very effectively it can be disposed among the

outcropping rocks in our alpine garden. Of late there has been considerable controversy as to whether it is a shade or sun lover. From the small, narrow, pointed leaves it suggests that it is an inhabitant of sunny districts, and here at Woodford I grow it in a south-east aspect, where it receives the whole of the sun from early morning to 5 p.m., and, as I write, the diminutive growths are a mass of ruddy blossom points. I grow it in a very free soil composed of sand, leaf-mould, old mortar, finely broken bricks and fibrous loam about fifteen inches deep and superimposed on 6 inches of rough drainage. From March to the end of July I copiously supply it with water, which is, I believe, an essential during their growing season for the successful cultivation of these choicer Saxifrages. When November arrives, and with it the fogs and smoke so well known to the suburban dweller, I erect a roof glass above the patch to intercept the dirt and excessive rainfall.

There is one other point which appears to me to be of considerable importance, and that is a thoroughly compacted rooting medium and very firm planting, while once or twice a year I top-dress with a compost of fine leaf-soil, small grit and silver sand. For this purpose I thoroughly dry the compost and run it in between the tiny growths on a fine, dry day. By this means it is possible to fill up the interstices between the growths in a manner quite impossible if the top-dressing is in the slightest degree moist or the plant clammy. Recently I have tried *S. burseriana* in the moraine, and it seems quite happy among the moist grit.

Some growers propagate this Saxifrage by means of cuttings. If the necessary attention and special skill is not available, a more rapid method of increasing one's stock is to take up a tuft, say, in April, and after shaking out the soil, carefully divide the bunch of fine roots. It will be found quite easy to cut up a patch as large as one's hand into ten or twenty plants, each with ample roots to support it, and if these are potted firmly in the above-mentioned compost and kept moist and "close" for a week or so, they rapidly make sturdy plants. They can, with care, be planted out into the rock garden direct.

R. A. MALBY.

SHRUBBY SPIRÆAS.

By making a selection of shrubby Spiræas it is possible to have a succession of bloom throughout the greater part of the year. One of the first, if not the first, to open its blooms is

Spiræa Thunbergii, producing clusters of white flowers on slender shoots. It is well suited for planting on raised banks. Height, 3 feet.

S. prunifolia flore pleno.—The double white flowers are profusely borne on arching shoots from

1 foot to 6 feet in length. It is a familiar garden plant, flowering in late March.

S. arguta.—The flowering season is from the middle of April till late May (see illustration). Height, 3 feet to 5 feet.

S. ariæfolia.—A strong-growing species, with plume-like panicles of creamy white flowers in June.

S. japonica.—This well-known species produces a succession of flat clusters of very red flowers from mid-June until the autumn. There are numerous varieties, of which the dwarf Bumalda, about two feet high, with heads of deep pink bloom, is one of the best.

SPIRÆA ARGUTA, BEARING CLUSTERS OF WHITE FLOWERS IN SPRINGTIME.

S. Douglasii.—In July and August this is one of the most charming of the shrubby Spiræas. The flowers are deep rose and freely borne on a dense mass of closely packed shoots.

S. lindleyana.—A very beautiful Himalayan species with white flowers disposed in large terminal panicles. The flowering season is September, and it grows to a height of 6 feet or 8 feet. Unfortunately, it can only be recommended with safety for Southern gardens. In Devon and Cornwall it grows luxuriantly. With this exception, all of the foregoing are perfectly hardy, and may be grown in any good garden soil.

SWEET PEAS FOR GARDEN DECORATION AND CUTTING.

AMONG annuals there is none to rival Sweet Peas for cutting, and during the last ten or fifteen years their rapid rise in popularity has added considerably to the attractiveness of our garden borders. The reason for this is not far to seek. In the first instance, the seeds are very cheap to purchase, no annual is easier to grow, and the plants produce quantities of flowers in almost every shade of colour. While for the purposes under discussion it is unnecessary to study the details of cultivation so closely as must be done to gain honours on the exhibition table, the main points must be followed if we are to get the best results from the plants to brighten our gardens and homes. Practically any garden, within reason, in town, suburb and country on which the sun shines in this isle will grow, or may be made to grow, Sweet Peas. The worst to deal with is a small, confined and stuffy town garden. Trench the ground 2 feet deep in autumn or early winter, and work in plenty of old decayed manure. In many gardens this will be sufficient soil preparation; in others much more must be done if success is to attend our efforts. Very light soils should be improved by adding plenty of cow-manure and top-spit loam. Heavy clay soils will benefit by frequent working and throwing up roughly in winter for frost and rain to improve it. Sand, road grit, wood-ashes, leaf-mould and basic slag will all assist to improve clay soils.

The Time to Sow Seeds.—To produce a display or supply of blooms over a long season from the end of May to October, it is necessary to make at least three sowings—October (or September in the North), February, and the end of March. For preference the two earlier sowings should be made in a cold frame or cool greenhouse, removing the plants later when about an inch high to a cold frame; and the third sowing outside.

Sowing Outside.—The drills or rings in which Sweet Pea seeds are to be sown should be about three inches deep, this amount of soil being covered over the seeds when sown. To facilitate watering in summer on light soils, the rings or drills may be prepared 3 inches or 4 inches lower than the general level of the garden. Sow the seeds thinly; it is waste to do otherwise, because later the young plants must be thinned to not less than 6 inches apart. Some growers prefer nearer a foot. The question of clumps *versus* rows of Sweet Peas is an oft-discussed point, the answer being that excellent flowers are obtained by both methods, always

providing that the plants in the rows have ample space in which to grow. When large quantities of flowers are required, rows are preferable; but for artistic effect in borders, groups or clumps of varying sizes, according to the width and length of the border, are the best. There is no better place for a row of Sweet Peas than planted as a screen to separate the vegetable garden from the flower garden. Much has been said and written about supports for Sweet Peas, yet nothing has been found to equal sticks to secure an artistic effect, and they should be used if obtainable at a reasonable price, those of Hazel being the best. The average height of the stakes required will be from 6 feet to 9 feet, according to the nature of the ground and the position.

Mulching with some old decayed manure during June, watering with clear water in dry weather, and occasional applications of liquid

and cutting. The orange pinks when Henry Eckford and Earl Spencer were first introduced did not cover themselves with glory in the border; but now we have Barbara and Melba, which are both satisfactory. It would be very difficult to find two growers in agreement respecting the twelve best sorts. The following are all first rate: King White, Clara Curtis, Barbara, Scarlet Emperor, R. F. Felton, Mrs. E. Cowdry, May Farquhar, Rosabelle, Elfrida Pearson, Edith Taylor, King Edward Spencer and Agricola.

A. O.

FIVE GOOD SWEET PEAS.

COLOURED PLATE 1487.

AMONG Sweet Peas of comparatively recent introduction, the five shown in the coloured

good constitution and the flowers do not burn so badly in the sun as many of this hue. They are well placed on the stems and a good bunch is very effective, either in the exhibition tent or used for house decoration. It received an award of merit from the Royal Horticultural Society in 1912.

Dobbie's Cream.—As its name implies, this variety, as well as Melba, was sent out by Messrs. Dobbie and Co. There are now quite a number of cream varieties, but the one illustrated will take a lot of beating. It is a very free-flowering Sweet Pea, and for that reason is very effective in the garden, while for show purposes it leaves nothing to be desired.

R. F. Felton.—Those who saw the magnificent bunches of this variety staged at the National Sweet Pea Society's exhibition last year are not likely to forget them. It is a very large flower of a varying shade of blue, the blooms being large

A BEAUTIFUL ROW OF SWEET PEA KING WHITE, WITH WHITE CANDYTUFT ON THE OTHER SIDE OF THE PATHWAY.

manure will assist in the production of vigorous growths and large, richly coloured flowers, borne on long stalks over a lengthy period. When cut frequently, there will be no flowers left to seed; but any that remain and fade on the plants must be removed, leaving a few pods, perhaps about the beginning of August, to mature sufficient seeds for home sowing, though it is doubtful economy when seeds are so cheap to purchase.

The Best Varieties.—The question of the best sorts for garden decoration and cutting can be dismissed in a few lines. Much more interest and pleasure is obtained from an up-to-date collection of named Sweet Peas than by growing the same sorts year after year. I have yet to see the Sweet Pea that holds a high place at exhibitions to-day which is unsuitable for the border

plate presented with this issue occupy a high position. They are all good for garden decoration and for exhibition.

Rosabelle.—This was raised by Mr. A. Malcolm and put into commerce by Messrs. E. W. King and Co. It is one of the prettiest of its colour. The flowers are large and good, and placed well on the stout, erect stems. It may best be described as a giant Marjorie Willis.

King Manoel.—Among Sweet Peas of dark maroon colour, this is a giant. The plants have a vigorous habit, and the blooms are of excellent substance. It was raised and distributed by Mr. George Stark.

Melba.—This is an exceptionally dainty and charming flower, the soft salmon orange tint always appealing strongly to ladies. It has

and well poised on the stems. It was raised and sent out by Mr. Robert Bolton, and last year was awarded the National Sweet Pea Society's medal as the best new variety sent to the trials in 1912. Under the society's rules it had to be grown at the trials last year to see if it remained true before the medal could be awarded.

SWEET PEA KING WHITE

This beautiful variety, shown in the accompanying illustration, has already won high honours, having secured an award of merit from the National Sweet Pea Society and the Royal Horticultural Society. It has very large flowers of excellent substance, and is being introduced by Messrs. Alex. Dickson and Sons, Hawtmark, Belfast, and Messrs. W. A. Burpee and Co., Philadelphia, U.S.A.

ROSE-GROWING IN TOWN GARDENS.

Ramblers and Their Uses.—In dealing with rambling Roses, of which there are a great number of species and hybrids, we have to consider, first of all, the purpose for which they are required. Those which do excellently as pillar Roses, or will clothe and cover arches and pergolas most effectively, often resent contact with walls; and, on the other hand, many which show to advantage where all the shoots are trained against a flat surface do not produce fresh growths freely enough to make them really useful for other purposes. The ramblers most generally selected are the wichuraianas and those of the multiflora scandens type. Both of these classes are immensely popular, and they include all the finest varieties a town gardener can employ for covering his arches and pergolas, and will also do exceedingly well when fastened to tall pillars. They have, unfortunately, a comparatively short flowering period (with few exceptions), but in that time produce such masses of bloom, and are, moreover, of such fine vigour and habit, that no one need hesitate to plant a few.

The Best Varieties.—The wichuraianas are generally to be preferred on account of their greater immunity from fungoid diseases, and of these there are so many good sorts that selection becomes a difficult matter. The following are all reliable: Hiawatha, single, crimson, white centre; Lady Gay, rose pink; Alberic Barbier, creamy yellow; Coquina, single, pink shaded; Leontine Gervaise, salmon rose, tinted yellow; Débutante, light pink; Jersey Beauty, single, creamy yellow; Excelsa, rosy crimson; Gardenia, light yellow to cream; and White Dorothy Perkins. All of these do well in towns, and many might be added to the list. Lady Gay is, I think, better than Dorothy Perkins, to which it is very similar, for though the latter has but little tendency to mildew, the former is practically proof against it, and in addition the flowers are slightly larger and a shade deeper in colour. The main pruning of wichuraianas should be undertaken as soon as possible after the bloom is over, and completed before the end of the autumn. This consists in cutting out from the base as many of the old shoots as can be spared. The strong, new growths are then tied into place to provide the bloom for the succeeding season, and where there is a superabundance of these, the weakest should be removed. In the spring little remains to be done beyond removing some of the late-started growths which have not matured and arranging those that are retained so that they will have as much air and light as possible. Newly planted wichuraianas should be cut down at once to within a foot of the ground, the object being to induce plenty of strong growth from the base. In dealing with climbers of all kinds, one must be prepared to sacrifice the bloom for the first year, and by so doing a great deal of time will be saved in getting the plant established satisfactorily.

Other Ramblers.—I have already hinted that the multiflora scandens class is less desirable, at all events to the town gardener, than the wichuraiana. Crimson Rambler, the most widely grown in this section, is anything but a good town Rose, for not only is it subject to mildew, but it is also liable to attacks of black spot. Blush Rambler, one of its progeny, is seemingly free from these weaknesses, and is a very beautiful Rose for an arch. Mrs. F. W. Flight (pink, semi-double flowers) is also good. Tausendschön (rose pink) is very pretty and distinct, but too

quite worth growing, though the colour is scarcely striking. Perpetual Thalia (white) blooms again in autumn.

The pruning of multifloras follows closely that of the wichuraianas, except that we get more of the following laterals or strong non-flowering shoots springing from the middle of other growths, some of which must be retained. Basal growths are seldom as numerous, and one can defer cutting out those which have to be discarded until the winter, which, of course, must be done in the case of the perpetual-flowering kinds. One other Rambler is of the greatest use in towns; that is the sempervirens Félicité Perpétue. This is a Rose for a bad spot, and it is safe to say that it will thrive where very few others would exist. Bleak or draughty gardens seem to suit it, and it is even at home on a wall facing north.

Wichuraianas seldom do well on walls or fences, and multifloras are even less suited for this purpose. When it is particularly desired to cover up a fence with the former, the best method is to train the stems up about a foot away from it, securing them to stout stakes, and they may then be carried and trained on to a trellis or wire-work above the fence. But there are many Roses better suited for such a position, with which I will deal in my next article in the issue of February 28. P. L. GODDARD.

THE STAKING OF SWEET PEAS.

MUCH of the disease now prevalent among Sweet Peas, in the opinion of the majority of experts, could be overcome if more attention were given to the prevention of checks during the early growth of the plants. Checks due to climatic influences cannot be held in control, but those resultant from cultural neglect need not occur. Experiments and observations prove beyond a doubt that the plants immune from disease during the flowering period (when the disease is so rampantly apparent) are those in which, from the first, a steady, sturdy growth has been maintained.

A Prolific Cause of Trouble is failing to supply adequate support to the young seedlings, which, in many cases, are allowed to fall over the sides of the seed pots or boxes and become injured, or they are matted together in a tangled mass of entwined tendrils, and separation for planting out cannot be accomplished without injury to practically every seedling. Is it small wonder that such plants fall

a prey to the ravages of disease, when, as seedlings, their constitution has been wrecked through careless neglect?

Early Support Necessary.—Directly the first tendril appears on the seedlings, the plants must be given supports of some kind, and for this purpose I know of nothing better than the twiggy tops of Hazel sticks, round which the young tendrils quickly enfold themselves. If the seedlings receive cool treatment, strong, stiff, erect growths will result, and when the plants are 5 inches or

I.—A CLUMP OF SWEET PEAS TRAINED ON SIMPLICITAS NETTING.

apt to mildew. Tea Rambler, as its name implies, claims kinship with another section, in which it was originally classed, though the habit is that of multiflora. It is best suited for a wall, and I will refer to it again in dealing with Roses for this purpose. The multifloras already include some important breaks in the direction of continuous-flowering kinds, but these are at present rather in the nature of a promise of good things to come than a realisation of the ideal. Trier, the first of these to arrive, is very perpetual and

6 inches in height, they can be planted out. Longer twigs should supplement those already in use, and these should be such as will uphold the plants until they reach the larger supports used for the flowering period.

The Final Staking.—For the final staking, having experimented with many substitutes, I consider Hazel or Elm sticks the most satisfactory, and so long as I can procure the sticks I shall keep to this old-fashioned plan.

Method of Staking Rows.—The tallest and twiggiest sticks should be firmly inserted in the soil to the depth of 9 inches or 10 inches on either side of the row. These may be arranged in either an upright or a slanting position. Personally, I prefer staking obliquely, as fewer sticks are needed, and, if the main growth be tied in, the breaks develop vigorously and a well-filled-out row of Sweet Peas is obtained. To guard against the ravages of strong winds, it is best to insert stout stakes at intervals in the rows, and connect these with wires woven through the sticks.

Clumps of Sweet Peas.—For staking clumps in the flower border nothing equals sticks. The newest and twiggiest ones should be neatly and carefully arranged, and these will harmonise well with all other surrounding shrubs or flowers. But sticks are not always to be had, therefore some substitute must be used. Fig. 2 shows an excellent arrangement made with thin Bamboo canes, two stout stakes and three wire hoops, and I think it is the most satisfactory substitute for natural stakes, both from the point of view of utility and artistic merit, and also that of economy, as the materials needed to make the circle will last several years, and can be easily put up or taken down. The materials required are two strong stakes 9 feet or 10 feet long, which should be firmly driven into the ground about twenty inches apart, and then three hoops put over them—the first hoop a foot from the ground, the next midway up, and the third fastened securely near the top. Then ten or twelve 10-foot Bamboo canes are arranged at intervals of 4 inches or 5 inches around the hoops and securely tied to them. During the growing season, if the shoots are tied in as often as necessary, excellent clumps will be obtained.

Wire-Netting of large mesh arranged in a circle round the stakes may be used instead of the canes; but I experienced complete failure with it, as it has the disadvantage of becoming very hot under the sun's rays and burning the plants, thereby causing injury. For this reason it is the least desirable of the substitutes for sticks, although many growers use it, as it keeps the plants well under control. The *Simplicitas* Patent Netting for all climbing plants is easily fixed and removed, and will serve for several years. For Sweet Peas in rows I found it excellent, and Fig. 1 well illustrates a clump of Sweet Peas thus trained, showing the advantages of the netting and also its one fault of "sagging." I found that birds did not like the see-saw they experienced when alighting on it, therefore the plants were left alone, quite a point in favour of the netting.

The foregoing notes refer chiefly to Sweet Peas grown for decorative and garden purposes; but whatever method be used, it is essential that the staking be done thoroughly. Exhibitors who cultivate their plants on the cordon system find that Bamboo canes or wires stretched upon a framework are more useful for their purpose than sticks, as the plants are denuded of every tendril and each stem is trained separately. Of course,

the initial outlay is somewhat great, for iron or wooden frames form the end supports and wires are stretched from end to end, and to these the 10-foot or 12-foot Bamboo canes are securely fastened. For keeping the stems in position, galvanised rings, easy to fasten, are now procurable. Users of them during the past season are loud in praise of their utility, and declare them to be almost indispensable. This method of culture requires daily attention, for the plants are kept rigidly disbudded, one, two, or three leads being allowed to each plant. Flowers obtained by this method are of enormous size, and, by the "honours" they win, repay the necessary outlay of money and care. However, the small grower with limited time and means who grows only for garden display will be well advised to use the substitute as illustrated in Fig. 2, and if he is unable to go to the trouble of tying in refractory growths, these can be kept in by winding some twine round and round the canes at intervals of a few inches, to which the tendrils will readily cling, although the effect of the clump is impaired thereby.

In conclusion, I tender my thanks to Messrs. Dobbie and Co. for their kindness in allowing me to illustrate these notes from photographs taken at their seed farm at Mark's Tey, Essex. S. M. CROW.

SWEET PEA HINTS FOR BEGINNERS.

PREPARE the ground as early in autumn as convenient. Trench as deeply as possible. If there is very little depth of good soil, take out

some of the subsoil and add any other good earth—"mellowed" top spit for preference. Use mixed farm-yard manure, at least a year old, bone-meal and soot throughout the spits, except in the top spit, in which use only bone-meal and soot. Keep the original top spit as the top spit. Tread all firmly except the top 6 inches or so. Ridge the soil at the top—two or three times during the winter will not hurt. Give a dressing of basic slag and a little kainit (a good lot of the latter if the soil is light) early in winter; sulphate of potash in spring.

Get good seed—much preferably English grown.

Chip all seeds and sow in sandy soil, except "white" and grizzled or wrinkled seed, which should be sown in a pocket or depression about half an inch deep, made with the point of the finger and filled with sand.

Sow in autumn in pots during the second week in October. Place a few half-decayed leaves over the crocks and three-quarters fill with good top spit soil and a little leaf-mould. The top quarter should be rather poor soil. Winter in frames. Pots to be sunk to the rims in ashes. Put a good number of pieces of Carrot among the pots and look at them at night with a light; kill all the slugs seen.

Pinch the leader to induce lower buds to grow out strongly in early spring, *not* in autumn.

Do not wait till after planting out to begin to kill slugs. Place small heaps of bran on the sites (where Sweet Peas are to be grown) during autumn and winter, and in mild weather visit them at night with a lantern and kill all the slugs seen. I kill thousands of slugs during the winter months. I have satisfied myself long ago that frost does not kill them. I am pretty well certain that they dodge the cold weather by going down the worm-holes.

Plant out about mid-April when the weather is favourable. Plant *very firmly*, but allow the top 2 inches or so of soil to be loose. Allow the weeds to grow on either side up to within 6 inches or so of the plants until the Sweet Peas are about one and a-half feet high. This will sound like preaching madness, but slugs feed on weeds, and if the soil all around the plants is kept bare, they have nothing else to eat and are much more likely to "go" for the Sweet Peas. Do not thin out, disbud or train until the haulm is about fifteen inches high, if growing for exhibition.

HAMMOND T. HINTON.

2 SWEET PEAS TRAINED ON A CIRCLE OF BAMBOO CANES.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Cherry Trees in Pots.—The early started trees will now be in bloom, and should be freely ventilated until the flowering period is over. Shake the trees several times during the early part of the day in order to disperse the pollen, and only employ sufficient fire-heat to keep the house free from frost.

Melons.—The earliest plants will now be growing freely, and may be stopped before they reach the top of the trellis, as by this means numerous side shoots will be produced, and on these the young Melons will soon be noticeable. When sufficient fruits are set, they should be regulated to three or four on each plant. Keep the growth well thinned in order to admit light among the foliage, but do not stop too many shoots at one time. Water freely when necessary, but avoid dabbling, as this is almost sure to prove fatal. Shut up the house early in the afternoon, lightly syringing the foliage at the same time. A night temperature of 70°, rising to 85° by day with sun-heat, will suit them well. A second plantation should now be made, and another sowing of seeds placed in small, clean pots for succession.

Pot Vines.—If these were started in November, the Grapes will now be well forward and have commenced to stone. During this period the temperature should not exceed 70° at night, for, while the seeds are in course of formation, there is a great strain on the energy of the plant, although growth may seem almost at a standstill. Be very careful in giving water at the roots, for if once allowed to become too dry, the crop will suffer seriously. When the berries recommence to swell, give liberal supplies of manure-water at the roots. Guano is one of the best manures for this purpose. Keep the foliage well regulated and shut up the house early in the afternoon, damping the floor and walls at the same time.

Plants Under Glass.

Caladiums.—The tubers may now be started into growth, either in boxes or small pots, and as soon as sufficiently advanced they should be potted into larger pots and placed on a gentle hot-bed, as by this means growth will be much stronger than if the plants are grown on an ordinary stage.

Achimenes.—Batches of these should be started in heat from now till the middle of April. Shake each variety out of the old soil separately, and plant the tubers in a compost of fibrous loam, peat and leaf-soil in equal parts, with sufficient rough sand to keep the whole in a porous condition. They are well adapted for growing in baskets hanging from the roof of a warm conservatory, or they may be cultivated in pots; but in this case thorough drainage is indispensable, and the addition of a little charcoal to the soil will be an advantage. Place the baskets or pots near the glass and syringe frequently with soft water until growing freely, when a thorough watering should be given.

Sweet Peas in Pots should not be allowed to become stunted for want of potting, but let the plants be carefully placed in larger pots in a compost of turfy loam and a little decayed cow-manure. A well-ventilated structure with plenty of light is the only place to grow them to perfection or early flowering. A few fine twigs should be placed in each pot to keep the plants in an upright position. Manure-water may be freely given when the pots become well filled with roots, also plenty of air may be applied.

The Flower Garden.

The Subtropical Garden.—The plants for this part of the garden should be raised or increased during the present month. Sow seeds of Ricinus, Jacarandas and Eucalyptus. Such plants as these afford a happy relief from the usual summer bedding, and may be intermixed with Lilies that flower during the summer and autumn. Hyacinthus candicans, large-flowered Cannas, Adiantum and Montbretias may all be associated with them.

East Lothian Stocks should now be ready for potting into 3-inch pots. Good rich soil should be used, and the plants grown in a slightly heated

pit; harden off as soon as large enough, and plant out during April.

Hardy Fruit.

American Blight on Apple Trees.—The present is a good time to destroy this pest, and one of the best remedies for the purpose is soluble paraffin; but a great deal depends on the way in which this or any other remedy is applied whether it will be a success or not. The preparation should be thoroughly worked into the affected parts of the tree with a hand-brush. Spraying or syringing is simply a waste of time and material, as far as this pest is concerned.

Spraying Orchard Trees.—Where trees are infested with lichen, they should be sprayed with some approved solution, and this should be done before the trees start into growth. For small orchards the "Knapsack" Sprayer is the best; and a quiet, still day should be chosen for the purpose. The operator should wear long rubber gloves.

The Kitchen Garden.

Sowing Seeds.—As soon as the state of the soil will permit, a sowing of some of the earliest subjects should be made. Turnip Early Milan may be sown on a warm border with as little delay as possible, but only a small quantity should be sown at this early date, as many of the plants are likely to run to seed. The main crop of Broad Beans may also be sown now, and hardy kinds of Peas sown at this date should be ready to gather by the third week in June. For this purpose, nothing among early Peas will give more satisfaction than The Pilot, 3½ feet. Brussels Sprouts may now be sown in the open, also Cabbage, Cauliflower and Leeks. Lettuce sown in the open now should be ready to cut in the first week of June. Pioneer, May King and Balloon are good for this purpose. Carrots may also be sown in the open for pulling in June.

Globe Artichokes.—The present is a good time to make plantations of these. Let the ground be trenched and manured, plant suckers from the best plants, and allow a space of 4 feet between the plants each way.

Potatoes may now be planted in cold pits or under a south wall, where protection can be given without causing an eyesore.

Radishes may now be sown on a south border and protected from birds by netting.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Plans for Cropping.—At this season of the year it will be well to make a rough sketch of the vegetable quarters and arrange the plots for the season's cropping. This will prove very helpful during the busy season, for, as spring advances, one has usually more to do than one can find time for. Many gardeners grow such crops as Carrots and Onions year after year on the same ground, and still get very good results. As a rule, however, it would not be wise to recommend this plan. Such crops as Potatoes, Leeks, Carrots and Beet should be followed by Peas, Beans, Onions and most of the Brassica tribe.

Shallots.—If one can get the soil into working order, no time should be lost in getting Shallots planted. The ground will require to be moderately firm, and plant the bulbs almost on the surface, only sufficiently deep to keep them in position.

Chives.—Where the Chives have got overgrown, the present will be a suitable time to make a fresh planting, which should be on well-prepared soil. Too often this useful vegetable is neglected, and, being much earlier and milder than Onions, it is a grand substitute for that crop for soups and salads.

Seakale.—Roots secured from the forcing crowns may now be placed in boxes of sand and stood in a cool Peach-house. These will soon commence to grow, and will be ready to plant out some time in March.

The Flower Garden.

Carnations.—Border Carnations which have been wintered in cold frames may be planted

any time now, provided the soil can be got into a fit state. The late Mr. Martin Smith told the writer that, in preparing ground for planting Carnations, if one could make an impression with the foot, it was not firm enough. Personally, I prefer planting in October; but this is not always convenient, or, I dare say, advisable, as some experience great difficulty in keeping them through the winter.

Dianthus.—These will make a fine show, and with very little expense. As advised for Carnations from seed, great care will be necessary to prevent the young seedlings from becoming drawn, which will render them almost useless. Sow now in moderate heat.

Petunias.—If one wishes to make a display of these beautiful annuals, it will be well to make a sowing towards the end of this week. If time and space permit, grow them on in pots instead of boxes, and the little extra trouble will amply repay one.

Lobelias.—With the more free and easy style of bedding now being adopted, Lobelias may very well be grown from seed instead of cuttings. Seed sown now will make fine plants by May. Should flowers appear before bedding-time, they ought to be cut off, which will materially prolong the flowering period out of doors.

Kochia trichophylla.—In favoured districts this will be found to make very interesting and effective dot plants among the lower-growing subjects in the flower garden. Sow the seed now and grow on in pots, keeping the plants near the glass.

Plants Under Glass.

Vallota purpurea.—At several important flower shows last autumn I saw this grand old favourite exhibited more than usual, and one was pleased to come across it again. Many made a note of it, doubtless with a view to adding it to their collection, and I consider it worthy of a place among the best of greenhouse plants. It is important at this season to see that it does not suffer from the want of water; this has been the cause of many failures.

Calceolarias.—These extremely decorative plants will now be ready to be potted into their flowering pots, which should be 8 inches to 10 inches, according to requirements. They should not be potted too firm, and as they begin to fill the pots with roots, feeding should commence. It is surprising in well-grown plants what an amount of artificial feeding they will stand. Continue to keep the plants near the glass without coming in contact with cold winds.

Gardenias will now be showing flower-buds, and may be treated liberally in the way of manure. If planted out, it is a good plan to mulch with farmyard manure. Pinch all growths that appear round the bud; these are often the cause of the latter not opening properly.

Bougainvilleas.—Where these are grown on the roof of the plant stove, they should now be pruned back and thoroughly washed. A good syringing with Quassia will generally rid them of green or black fly, to which they are very subject.

The Hardy Fruit Garden.

Planting.—All hardy fruit may still be planted, but it will not be wise to defer this work much longer, as late-planted trees never get the same chance to recover from the shift. In any case, recently planted trees should have a mulching of stable litter placed over the roots to protect them from late frosts. Pruning and nailing of all wall trees should be completed now.

Early Pears.—Some of the earlier varieties will be showing flower, especially on sheltered walls facing south. These should be protected either by herring-nets or some branches of Yew tied on to the trees.

Fruits Under Glass.

Vines in houses closed down last month will now be beginning to move, and the temperature may be slightly increased, but by no means excite them unduly at this stage. After this date the later varieties will show signs of moving under the influence of the sun. When this is the case, it will be as well to close them down and let them come on gradually.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON VEGETABLES.

French Beans.—A batch of seeds of these quick-growing plants should be sown in a started vinery, or in a Melon or Cucumber house where a warm, moist heat of 60° is available. Two methods are adopted by growers. One, which I prefer, is to sow five Beans in a 3½-inch pot in light soil, transferring these wholly to an 8-inch pot when the first rough leaf is formed. The plants, if handled carefully, grow away rapidly. The second plan is to sow the seed in 8-inch pots at once, half filling the pots, and earthing the plants up as they grow. This method entails more space than the other at the start, which may not be always convenient. A compost of loam and leaf-mould in equal parts will suffice, with but a moderate quantity of water for a start, increasing it as growth proceeds and supplying liquid manure frequently when the Beans are forming. Osborne's Forcing is still a good early kind; while Ne Plus Ultra and Canadian Wonder are excellent for later sowing.

Potatoes in Pots.—This is a convenient method of obtaining an early supply of useful tubers, because they can be moved from place to place quite easily. A Peach-house or vinery just started affords a suitable site for a start, and, until the growth is several inches above the soil, any dark, warm place will serve the purpose. Pots 12 inches in diameter will suffice. Place one tuber in each pot half filled with soil, which should be of a light, leafy character. Add more soil as growth proceeds, and give an abundance of water when growth is being freely made. As to varieties, none is better than Ringleader, Myatt's Ashleaf, or Sharpe's Victor, with May Queen to follow.

Peas in Pots and Boxes should now be sown for succession and early planting outside. If sown now in slight heat, hardened off, and grown sturdily in cold frames until suitable weather arrives for putting them out, such sowings will produce better results than the earliest sowings in the open. If sown in 3½-inch pots with five seeds in each they are easily transferred to the open, which is also the case if sown in ordinary cutting-boxes with a light, leafy compost, to which the roots cling, rendering the start again into growth more rapid. A second sowing in ten days' time in boxes stood under a south wall outside will succeed those sown in cold frames, and will come along rapidly. Those of a Marrowfat type are the most desirable; Pilot for early use, with Duke of Albany to follow later, and Alderman, Edwin Beckett, Centenary, and Prizewinner in between.

Brussels Sprouts.—To obtain a continual supply of firm Brussels Sprouts, a long season of growth is an absolute necessity. The ordinary way of sowing the seed outside with the bulk of the Brassica tribe at the end of March or early in April does not apply to Brussels Sprouts for a full and early crop. To obtain plants from 3 feet to 4 feet high of the stronger-growing varieties like Exhibition, which provide Sprouts at the end of October in quantity, a pinch of seed should be sown in sandy soil about the third week in February in gentle heat under glass. When the plants are well above the soil, move them to cooler quarters to induce a sturdy habit of growth. When they are large enough to handle, prick them out, 3 inches apart, into boxes or a made-up bed of light soil in a cold frame. Encourage free yet sturdy

growth, and when 5 inches high the plants should be put out into their permanent quarters, lifting each plant with a trowel, retaining a nice ball of soil about the roots, which should be watered before lifting. To grow Brussels Sprouts, the soil should be trenched at least 2 feet deep and heavily manured some months previously.

Swanmore Park, Hants.

E. MOLYNEUX.

CLASSIFICATION OF SWEET PEAS.

WE quote the following from the National Sweet Pea Society's Annual for 1914, a publication that ought to be in the hands of every lover of these fragrant flowers. Particulars concerning it will be found on page 77. The list of too-much-alike varieties referred to is published in the "Annual": "The floral committee presents the following as an up-to-date selection of varieties placed in alphabetical order. The committee wishes to draw the attention of members to the list of too-much-alike varieties before selections are made, because in some colour sections the varieties recommended may be so nearly alike that they cannot be shown together in the same competitive exhibit at the society's exhibitions. * Indicates a grandiflora variety; all others are waved.

Bicolor.—Arthur Unwin, Mrs. Andrew Ireland (F.C.C. 1908) and Mrs. Cuthbertson (A.M., R.H.S., 1912).

Bicolor (Dark).—Marks Tey.

Blue (Light).—Anglian Blue, Flora Norton Spencer and Princess Mary.

Blue (Dark).—Blue Jacket, Lord Nelson Spencer and Mrs. G. Charles.

Blush (Pink).—Lady Evelyn Eyre, Mrs. Harcastle Sykes (A.M., 1905) and Princess Victoria (A.M., R.H.S., 1907).

Blush (Lilac).—Agricola (A.M., 1912) and Marion.

Carmine.—John Ingman (F.C.C., 1904).

Cerise (Pale).—A. A. Fabius and Edith Taylor.

Cerise (Deep).—Decorator, Kathleen and Rose Diamond. *Cream, Buff and Ivory*.—Clara Curtis (F.C.C., 1909). *Cream (Dobbie's)* and *Majestic*.

Cream Pink (Pale).—Duplex Spencer, Gladys Burt and Mrs. Routzahn.

Cream Pink (Deep).—Margaret Atlee, Mrs. R. Hallam and Prince Edward of Wales.

Crimson.—King Edward Spencer, Maud Holmes and Sunproof Crimson (A.M., 1909).

Fancy.—Charles Foster (A.M., 1909), Coronation and Prince George.

Lavender.—Lavender George Herbert (A.M., R.H.S., 1912), Masterpiece (A.M., 1910) and R. F. Felton (A.M., 1912; S.M., 1913).

Lavender (Pale).—Moonstone, True Lavender and Walter P. Wright.

Lilac.—Dorothy.

Magenta.—Menie Christie.

Marbled and Watered.—Birdbrook, May Campbell (A.M., 1911) and Veronique.

Maroon.—King Manoel, Mrs. E. Cowdy and Nubian.

Maroon Red.—Brunette (A.M., R.H.S., 1912), Red Chief and Victor Unwin.

Mauve (Pale).—Bertha Massey, Bertrand Deal (A.M., 1912) and Mauve Queen (A.M., 1911).

Mauve (Dark).—Mrs. J. C. House, Queen of Norway (A.M., 1906) and Wenvoe Castle.

Orange Pink.—Edrom Beauty (A.M., 1909), Helen Grosvenor and Orange Perfection.

Orange Scarlet.—Edna Unwin (A.M., R.H.S., 1909), and Thomas Stevenson (F.C.C., 1911).

Picotee Edged (Cream Ground).—Evelyn Hemus (A.M., R.H.S., 1907), Helen Williams and Mrs. C. W. Breadmore.

Picotee Edged (White Ground).—Elsie Herbert (A.M., 1906), Marchioness of Tweeddale and Mrs. Townsend.

Pink (Pale).—Elfrida Pearson (A.M., R.H.S., 1910).

Pink (Deep).—Countess Spencer (F.C.C., 1901) and Hercules.

Rose.—Rosabelle.

Salmon.—Barbara (F.C.C., 1911), Inspector and Stirling Stent (F.C.C. and S.M., 1910).

Salmon (Pink).—Isabel and Lady Miller (A.M., 1912).

Scarlet.—Red Star (A.M., 1911), Scarlet (Dobbie's) and Scarlet Emperor.

White.—*Dorothy Eckford (F.C.C., 1902), King White (A.M., 1912), Nora Unwin (A.M., 1907) and White Queen."

THE CAMPANULAS OR BELLFLOWERS.

[Replies to Criticisms.]

I N referring to the various criticisms upon my articles on the Campanulas, perhaps you will allow me, in the first place, to thank those who have so kindly contributed for their courtesy and for the points of interest and value they have raised. It is indeed difficult in writing on a subject such as the Campanula to steer the middle course and to keep clear of Scylla and Charybdis, as typified by condensation and prolixity. The subject is so great and affords so many critical questions that the temptation to write at length is almost irresistible. But one must remember that all the readers of THE GARDEN are not enthusiasts in the Campanula, and that it were better to err on the side of condensation than on that of undue length. If, however, I have committed the fault of being too concise, this may be overlooked, because it has been the means of bringing several notes of great interest and special value from various cultivators of this charming class of plants.

Taking these in order, I owe very special thanks to Mr. Reginald Farrer, who has both unique opportunities of studying the plants and who can also convey his knowledge in the most attractive fashion. The nomenclature of Campanula Allioni or C. alpestris is, I think, the first point he has raised. In retaining the name of C. Allioni I was only following in a humble way a number of first-class authorities. I endeavoured, as far as possible, to keep to the nomenclature of the "Kew Hand List," and, failing that, of the "Index Kewensis." It is well, I think, to have some authority convenient of access to the many as a court of appeal in such questions as these. It is better to accept such for working purposes rather than to be too strict in nomenclature, especially when the question of priority is concerned. It is quite true that the name of C. alpestris has the priority; but when we find that C. Allioni has consistently held the field for many years, we may well retain it until the "Kew Hand List" is revised. I admit that this is an argumentative question, but it is unfortunate indeed that a plant with a long record under one name should become changed, to the confusion of many. I submit that for one who may be misled into buying a plant as C. alpestris, under the impression that it is different from his old friend C. Allioni, there are ten who would be disposed to complain that when ordering C. alpestris they only obtained our old favourite C. Allioni. I am not prepared to admit that priority should always have the preference. What, for example, of the lovely Crocus iridiflorus? By all the rules of priority it should be C. byzantinus, an altogether misleading name. When we come to the question of the identity of C. cæspitosa with C. pumila or C. pusilla, we touch upon quite different points. In writing of these Campanulas I dealt with them from a gardening standpoint; and from what I had seen of the plants grown under any of these names I was forced to the conclusion that they were practically the same for garden purposes. In this case the "Kew Hand List" differentiates between C. cæspitosa and C. pusilla. Most recent writers on the subject have, however, discarded the distinction between the two, and Mr. Farrer,

with his usual candour, confesses that he himself was an offender as late as last year. His note led to my looking up several references on the subject, and among them I find an excellent paper by Mr. Maurice Prichard on the Campanulas, which appears in the Journal of the Royal Horticultural Society, Vol. XXVII., Part I., 1902. Under the name of *C. pumila* Mr. Prichard gives as synonyms *C. pusilla* and *C. cæspitosa*. In the same publication, Vol. XXXII., June, 1907, there is the report of a paper, "An Annotated List of the Species of Campanula," by Colonel R. H. Beddome, in which, under the title of *C. cæspitosa*, Scop. "Flor. Carn.," second edition, page 143, t. 4 (1772), Colonel Beddome gives as synonymical *C. pusilla*, Hænke, in "Jacq. Coll.," II., page 79 (1788), and *C. pusilla*, Sims, Botanical Magazine, Vol. XV : 512. Colonel

and which is a different thing from that usually grown in botanic gardens by the same name.

With respect to some other Campanulas more briefly referred to, one may say that *C. stenocodon* is rather like one or two of the *C. cæspitosa* forms which I have secured, but which are rather after the *C. rotundifolia* type. Possibly I should have described it in more detail, but space was precious. I see it is generally said to be near *C. rotundifolia*, and perhaps only a delicate form of it. As for *C. tridentata* and *C. Saxifraga*, my experience has been the same as an earlier one of Mr. Farrer, who says, in that charming book, "My Rock Garden," that "they are very likely two different forms of the same species—*Saxifraga* from the Caucasus, and *tridentata* from further South in the Lebanon ranges.

However, the differences between them are of a

THE BEST WHITE, SCARLET AND MAUVE SWEET PEAS.

I THOUGHT perhaps some of the readers of THE GARDEN would like to hear the results of my trials in the scarlet, white, mauve, and lavender shades of Sweet Peas. I have grown my Sweet Peas in clumps in their different varieties, also in exhibition rows, and planted a foot apart. I obtained the following sorts of whites: Etta Dyke, White Queen, White Pearl, Freda, Moneymaker, Florence Wright and Nora Unwin, and planted three plants of each in clumps, giving each the same conditions and treatment in every way. In the exhibition row they were planted in rotation, but six plants of each.

Etta Dyke's great fault is in throwing a lot of plain standards, but it is a very free bloomer and seeder. White Queen is a very strong grower, but all the plants gave way suddenly to streak, the only Sweet Pea out of the eighty varieties I grow to be attacked; it is rather too creamy to be a tip-top white. White Pearl is a very good waved variety, but hardly robust enough, and gave out rather early in the season. Freda is a great pleasure to me, as it throws fours in profusion on very long stems perfectly fixed. I picked flowers from the middle of May up to the end of October; the plants reached over fifteen feet in height. Moneymaker is also very good, with strong, lasting petals. Florence Wright has not been so strong, and has not bloomed so freely. Nora Unwin is still a very fine garden variety, but not so good for exhibition.

Now for the scarlets which I have grown. Scarlet Monarch is not large nor robust enough and only throws threes, but lasts in bloom very well; in fact, it is the best in that respect. Red Star I think the very best scarlet up to date. It throws fours in great quantity, and grows quite 15 feet high. Scarlet Emperor is also very good, but does not throw fours in quantity,

as exhibition varieties must do. Vermilion Brilliant is also a favourite of mine, although its fault with me has been that its blooming season is short. It is a medium grower and quite fixed. Regarding lavenders, W. P. Wright has been very disappointing. I tried two small packets of seed. One I put in a clump, but only three plants grew, and they turned out two dirty whites and a violet maroon. From the other packet I had eight plants. One was a dirty white, another a plain standard Lavender, and the rest quite good. True Lavender has been perfect, all the flowers being pure and good; if there is a fault, it is that I should like to see rather more colour in the blooms. In dark mauves I can pick two good ones, viz., Queen of Norway, which is first class, and Tennant Spencer a very good second. In light mauves, I am just going to mention two which I consider the cream of the lot. R. F. Felton is a very fine grower and throws plenty of fours, but my fancy is Mrs. Heslington, a very robust grower, and I picked blooms with 12-inch stems.

S. ARNOTT.

Pington, Devon.

PLANTING II. 1880-1914

PART OF THE NATIONAL SWEET PEA SOCIETY'S EXHIBITION HELD IN LONDON LAST JULY.

Beddome adds, "generally sent out under the name of *pumila* or *pusilla*."

Going back to an earlier date, we find that Alphonse de Candolle, in his "Monographie des Campanulées" (Paris, 1830), includes *C. cæspitosa*, *C. pusilla* and *C. pumila* under *C. cæspitosa* of Scop., and informs us that *C. pusilla* of Hænke is not distinguishable from *C. cæspitosa*, Scop. The latter is retained by de Candolle as the prior name and the one which is most used. Of course, this does not conflict with Mr. Farrer's discovery of what he calls the true *C. cæspitosa*. But so far as Alphonse de Candolle's views are worthy of respect, he is on the side of those who say that *P. cæspitosa*, Scop., and *C. pusilla*, Hænke, are the same. Of course, this is in conflict with the "Kew Hand List." The authorities for the name of *C. pumila* for the plant are the Botanical Magazine, t. 512, and Roem. et Schultz, Syst. 5, page 96. Schott, Nym. and Kotschy, Analect., Bot. 13, would appear to be the authorities for *C. modesta*. But I believe I now have the plant which Mr. Farrer calls the true *C. cæspitosa*.

minute nature, and they may be treated as one in the garden." Again, in that delightful compendium of information, "The Rock Garden," Mr. Farrer says: "*C. tridentata* (to include *C. Saxifraga*) is a valuable, easy, Levantine plant." Then Colonel Beddome says that *C. Saxifraga* is "a pretty species, very near *tridentata*." I appear to have gone astray in speaking of *C. valdensis* by itself, as, on the authority of the "Kew Hand List," it is a variety of *C. linifolia*, which it treats as a distinct species from *C. rotundifolia*. Where authorities differ, where can light be found?

The point of *C. pumila* being a lime-hater has occasioned some most valuable correspondence. I must, to some extent, admit that I have largely followed tradition in my treatment of this plant by avoiding lime. One could say a great deal more on the different questions which have been raised, but the points omitted must be held over. I have already made too great inroads upon space.

THE GARDEN.

No. 2205.—VOL. LXXVIII.

FEBRUARY 21, 1914.

NOTES OF THE WEEK.

A Miniature Daffodil.—Just now the dainty little flowers of *Narcissus minimus* are unfolding in the outdoor garden, opening as it were the Daffodil season. It is impossible to praise this perfect little gem too much. It is a true trumpet variety, yet it is but 3 inches high and not more than half an inch in diameter. The colour is rich yellow, and for planting in little nooks in the rock garden or other sheltered places we know of nothing more pleasing. It is a native of Spain, and should be freely planted where early outdoor flowers are appreciated.

Transplanting Alstroemerias.—The genus *Alstroemeria*, or Herb Lily, was at one time much more largely grown than it is at present. Why the plants have dropped out of favour is not easily understood, for few plants need less attention to grow them successfully, either in pots or in the open ground. The present time is the most suitable for transplanting them. The ground should be well trenched and the tubers placed from 6 inches to 9 inches deep. They seldom succeed if planted near the surface. When once established they will continue to brighten the garden for many years, and the handsome flowers are excellent for cutting, remaining fresh for a long time.

An Attractive Acacia for a Small Greenhouse.—The Silver Wattle (*Acacia dealbata*), better known to many people as *Mimosa*, is undoubtedly the best of the genus, and is an excellent plant for helping to furnish a large conservatory where it has room to grow into a good-sized tree. But those who possess only a small greenhouse will find a very valuable substitute in *A. longifolia*. Plants of this beautiful species can be grown in pots, and will flower in a small state from 2 feet to 3 feet high and upwards; they are very ornamental with their graceful sprays of flower intermixed with the beautiful blue *Coleus thyrsoideus*. By cutting back the *Acacia* as soon as the flowering period is over, dwarf, compact plants can be obtained.

Lachenalias in Small Pots.—February being the month when with cool greenhouse treatment these bulbs are in flower, we would like to call our readers' attention to their value as plants to grow in dwarf pots. Nine or ten bulbs in a 6-inch pot make a fine show. They are a welcome change from the usual spring flowers, and, what is a strong point in their favour, they are very lasting when in bloom. Some of the newer varieties, such as *Brightness*, *John Geoghagan*

and *Shiner* among the claret-edged kinds, and *Rose Barton*, *His Reverence* and *W. E. Gumbleton* among the green and the yellow ones, are distinct advances on most of the older sorts. *Cawston Gem* and *Nelsonii*, however, still hold their own. The six new varieties just mentioned were all raised by Sir Frederick Moore at Glasnevin.

new surface. Hyacinths are among the number of those which are thus affected, and it was our seeing a collection in which this was very marked that has led us to insert this warning. The only safe plan is to bury all new pots in the ground for six or eight weeks before they are used for the first time. This effectually removes their sting and makes them as harmless as old ones.

NARCISSUS MOSCHATUS OF HAWORTH, A SMALL-FLOWERED VARIETY SUITABLE FOR THE ROCK GARDEN.

Narcissus moschatus of Haworth.

This small white Spanish Daffodil created a deal of interest when shown in quantity by the Wargrave Plant Farm at a recent meeting of the Royal Horticultural Society. It is a miniature Daffodil with a creamy white trumpet, attaining a height of about nine inches. This variety is recommended for the rock garden, and when planted in nooks among the rockwork and left undisturbed will become established and make a charming show. It is also adapted for naturalising on grassy slopes facing North in partial shade.

The Government and Horticulture.

The first report of the horticulture branch of the Board of Agriculture has just been published, and gives us a good insight to the work that is being done by this newly constituted branch. So far, plant diseases appear to have been the principal items dealt with, and it is a good sign to find that active steps are being taken to stamp out such as Gooseberry mildew, wart disease of Potatoes, Larch sawfly and the silver-leaf disease. The export trade in agricultural and horticultural produce is also receiving serious attention, and on the whole the report is a satisfactory one. Copies can be obtained through Messrs. Wyman and Sons, Fetter Lane, E.C., price 2s. 2d. each.

Sowing Hollyhock Seed.—Owing to the disease affecting these noble plants for many years past, the method of propagating them by cuttings has almost died out. The best way to ensure a good display of flowers is to treat

The Danger of New Pots.—It is very probable that the deleterious effects of new pots on the roots of certain plants are unknown to some of our readers. Most people are content to soak them in water before using them for the first time, in order to prevent undue absorption of moisture from the soil. This operation, however, does not remove the offending something that causes the roots to turn brown and ultimately decay wherever they come into contact with the

the plants as biennials, sow the seeds in September, and winter the young plants in a clean cold pit. By this means a good display of early flowers may be obtained. But good results may also be had by sowing in February and placing the pans or boxes over gentle bottom-heat. As soon as the seedlings are large enough to handle, they should be potted into 3-inch pots and grown in a pit with a temperature of 60° and quite near the roof glass.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Staking Sweet Peas.—In last week's excellent article on "Staking Sweet Peas," by S. M. Crow, he mentions the one fault of sagging in "Simplicitas" Patent Netting Circles. May we, as the inventors, be allowed to point out that we are this season eliminating this very small fault in an otherwise perfect support by the introduction of a centre wooden ring. We have also introduced an iron foot to prevent the centre stake from working loose in the soil.—THE BOUNDARY CHEMICAL COMPANY, LIMITED.

Earwigs Eating Buddleia Foliage.—I notice in THE GARDEN, page xvi., issue February 7, under "Miscellaneous," in the "Answers to Correspondents," a note to an enquiry about earwigs eating Buddleia, and you seem rather sceptical

were only too well aware of the irregular and sluggish behaviour of the bulbs. They had not responded to heat as they should have done, and in some cases the bulb was blind. It was pointed out by two large dealers that the season of 1913 was about two weeks earlier than that of 1912, whereas their Hyacinth bulbs were lifted at the date in both years. It is always unwise and risky to generalise on a too limited experience, and this is what, I fear, has been done. A longer acquaintance with the practice will either "kill or cure" it. Meanwhile we must go "steady," until this experimental stage has been passed. I would also like to say that I am by no means sure that I was right in what I said about bottom-heat. I find that there are advocates both for giving and withholding it, but that the majority favour it if it is not too strong.—JOSEPH JACOB.

Two Useful Midwinter-Flowering Plants.—After the Chrysanthemum season is passed there is often a slump in plants suitable for the decora-

till there is danger of frost. The second plant is *Eupatorium vernale*, which many readers of THE GARDEN will be well acquainted with. The requirements of these two plants are practically identical, except that the latter, being of dwarfer habit, may be accommodated in a cold frame till the end of the year.—E. HARRIS, Lockinge.

Is the Sea Buckthorn Poisonous?—Referring to the observations on wild birds and the Sea Buckthorn under "Notes of the Week," issue January 10, can it be that the berries of this native shrub are poisonous, and is this the reason why, in some parts of the country at least, the berries remain untouched by birds even in a hard winter? So far as the alleged poisonous properties of the berries are concerned, there is an amusing reference which I have seen quoted from Rousseau's "Réveries VII. Promenade." After eating a quantity of berries, which he found "very pleasant," he was warned that they were poisonous. "Nevertheless," he says, "I felt as I feel now, that every natural production that is pleasant to the taste cannot be harmful unless perhaps through excess. I confess, however, that I kept a watch on myself for the rest of the day, but, beyond a certain uneasiness, I felt no ill-effects. I supped very well, slept better, and rose in the morning in perfect health, having swallowed the evening before some fifteen or twenty of the berries of this terrible Hippophaë, a small quantity of which is poisonous, as they told me at Grenoble the next day." To the present writer the berries are unpleasant, but, is it really true "that every natural production that is pleasant to the taste cannot be harmful unless perhaps through excess?"—C. Q.

Saxifraga burseriana.—While the bruit of mortal conflict between Mr. Reginald Farrer and Mr. Clarence Elliott respecting the habitat of *S. burseriana* is still ringing in our ears, I think a few remarks concerning this dainty and early flowering alpine may be apposite. Whatever may be the behaviour of *S. burseriana* in shade, I think a glance at some plants of it which I have growing upon a moraine should convince the most sceptical that, subject to what I say about water supply, a position in full sunlight conduces towards a plentiful display of blossom. On each of three clumps not exceeding 3 inches in diameter I counted early in February upwards of thirty flower-spikes. The moraine in question is described by me in a chapter upon rock gardens which will be found at the end of "Gardens for Small Country Houses," by Miss Gertrude Jekyll and Mr. Lawrence Weaver. To one who knows how apt all Saxifrages are to "burn" in fierce sunlight, it goes without saying that a plentiful supply of water is necessary for *S. burseriana* during the summer. In the case of my moraine, this supply is provided by means of a perforated pipe. The initial expense of such an installation is soon paid for by the saving in labour of hand watering thus effected, and also by the decreased wastage of plants which might otherwise perish through drought. As the result of the accidental inclusion of one clump of the *Saxifraga* beneath a sheet of glass provided to meet the wants of the damp-hating *Androsace sarmentosa*, I am able to say that the effect of covering this Saxifrage with glass during the winter months upon its flowering are very slight indeed. Glass for protecting the opened flowers is another matter. I confirm all that has been said as to the desirability of heaping up dry chips of rock round the necks of moraine plants during the winter.—RAYMOND E. NEGUS, Walton-on-Thames.

A FRUITING SPRAY OF THE SEA BUCKTHORN.

about it. I have a plant of *B. variabilis* on my house which is quite spoilt by earwigs every summer, some of the leaves being eaten or torn to tatters and hanging by shreds. The young flower-spikes also have the ends eaten off. I have not the smallest doubt about earwigs being the culprits; they seem quite mad after the Buddleia. Two other trees of *B. variabilis* in the garden in the open are not much attacked. I trap the earwigs in the usual way in brown paper, and have also had to spray the trees with arsenate of lead, which, I presume, settles the pests, though I have not had the satisfaction of seeing the corpses.—C. G. O. B., Farnham.

Prepared Hyacinths.—With reference to an article from my pen which appeared in THE GARDEN for August 9, 1913, on "Prepared Hyacinths," I am sorry to say that they have not been the success this season that previous experience led me to anticipate. When I was lately in Holland, I found that the Dutchmen

tion of the cool greenhouse or conservatory. It is not everyone who has the means and convenience to fill their greenhouse or conservatory at this time of the year with expensive forcing plants and bulbs. Neither is it desirable to do so when plants less expensive, but none the less beautiful and useful, can be grown. The two plants which are the subject of this note are easily grown, and require nothing more than shelter from frost from the time the cuttings are rooted. The first is *Salvia Heeri*, which flowers during the greater part of January and February. The flowers are brilliant scarlet, borne on long, slender spikes or branches. They are most useful for cutting for indoor decoration, as they last for a considerable time in water. Like most other members of this race, they may be readily increased by cuttings inserted in sandy soil in the spring and placed under a hand-light. When established in pots, they should be grown in an exposed situation out of doors, and kept there

PEAT MOSS MANURE: IS IT INJURIOUS?

SEVERAL enquiries have reached us recently as to the advisability of using peat moss litter manure in the garden. There is no doubt that in some instances, where it has been dug into the soil fresh from the stables, it has proved injurious to plant-life, though as a top-dressing it has proved excellent. Owing to the increasing difficulties in obtaining straw manure, this question is one of vital importance. We therefore invited the opinions of a number of scientific and practical men in various parts of the United Kingdom. Herewith we publish a selection of these, and it will be seen that there is some difference of opinion on the subject.

GIVEN the choice between manure made from peat moss or straw, I should use the latter. It gives the best results in the long run. The peat moss manure, though, is distinctly valuable, especially on light soils, which dry out quickly. Once it is thoroughly moist, it retains its water supply in a fashion all its own, and the plant roots can get at it even when the surrounding soil is dried out. I have never seen it acting injuriously, but it is only right to say I have only seen it used on the extensive scale for the culture of vegetables.

Cambridge. R. H. BIFFEN.

I FEAR I cannot give you any very definite information about peat moss litter as manure. I know that when kept for some months, and when turned a couple of times, it is an excellent surfacing for Primulas, Wallflowers, &c. I tried it here one year with some vegetables, and with some Primula seedlings as a manure, and in both cases the result was not satisfactory, and the men have a great prejudice against it as a manure. It makes no difference to them in any way; hence they have no interest in the matter, and as it is easier for them to work than cow-manure, I came to the conclusion that there must be some grounds for their dislike of it. I was not at all satisfied that it was in fault as regards the seedling Primroses; but the man in charge of them, an experienced man, still strongly maintains that it was the manure. Personally, I prefer cow-manure if I can get it, or even well-decayed stable litter. We found that for small stuff and for ground where bulbs were that the most useful and safe manure was old hot-bed material, used the following spring; that is to say, hot-beds which were made up in January, 1913, are now being used as manure. This is very well decayed and crumbles down easily.

F. W. MOORE.
Royal Botanic Gardens, Glasnevin.

PERSONALLY, I would prefer peat moss litter manure to straw manure. The original acidity of the peat absorbs a high percentage of ammonia, and is, therefore (all other factors being the same), of higher available nitrogen value than straw manure. In addition, it has a distinct value from a physical point of view; it raises the water-holding power of the soil. I know of a garden close to this city where peat moss litter manure is used entirely, and the gardener believes absolutely in it as a good crop producer. I have in my own gardening found it excellent for herbaceous borders.

D. HOUSTON.
Royal College of Science for Ireland, Dublin.

YOUR letter of February 7 has been referred to me for reply. Experiments at this College have shown the absorptive power of good peat moss litter to be about three times as great as that of straw, but different samples vary considerably in their power of absorbing liquids. At the Armstrong College, Newcastle, for example, it was found that one sample absorbed eleven times its own weight of water, while another sample took up only nine times its own weight. Chemically, peat moss contains more nitrogen than straw, but considerably less potash and a little less phosphoric acid. Average analyses made at this College are as follow:

	Peat Moss.	Straw.
	Per cent.	Per cent.
Nitrogen ..	0.8	0.5
Phosphoric acid ..	0.1	0.3
Potash ..	0.2	1.5

The nitrogen in peat moss, though greater in quantity, is probably less available to the plant than that in straw, so that peat moss in itself may be considered to be of less manurial value than straw. But, owing to its greater absorptive power, the manure made from peat moss litter is richer than manure made from straw, as the following analyses made by Dr. Dyer (see "Standard Cyclopædia of Modern Agriculture") show:

	Stable Manure made with Straw.	Stable Manure made with Peat Moss.
	Average of 3 samples.	Average of 2 samples.
	Per cent.	Per cent.
Water ..	70.03	77.84
Organic matter	24.28	18.02
Phosphoric acid	0.48	0.37
Lime ..	0.70	0.33
Potash ..	0.59	1.02
Magnesia, &c.	1.30	1.08
Siliceous matter	2.62	1.34
	100.00	100.00
Total nitrogen	0.62	0.88

It will be noticed that the peat moss manure contains a good deal more potash than the straw manure, although the peat moss itself was deficient in potash. The difference is due, of course, to the potash absorbed from the excrement of the animals. Peat moss manure contains more nitrogen than straw manure, and more potash, but a little less phosphoric acid and less lime. The physical effect of peat moss manure in the soil is, of course, rather different to that of straw manure, because the manure is always "short." We have used both here, but have not noted anything harmful about the peat moss. I am writing to a farmer who has had considerable experience with it, and will let you know what he says in due course.

G. H. GARRAD.
South-Eastern Agricultural College, Wye, Kent.

IN reply to yours *re* peat moss litter, we do not use it here as a manure, as we have not found that which we have had from London satisfactory.

F. R. WILKINSON (Principal).
The Horticultural College, Swanley, Kent.

PEAT moss litter is best dug into the ground, as if left on the surface the pieces of peat are somewhat of a nuisance, as they do not decay readily. This manure, however, adds to the acidity of the soil and thus has a slightly deterrent effect on the growth of vegetation, and its value is more due to the fact that it soaks up liquid manure, and thus saves fertility that would run to waste, rather than to its own manurial value.

The fibre is, of course, good for "opening up" a stiff soil, but, ton for ton, good stable manure is superior.

P. McCONNELL.

MY experience with peat moss litter manure is neither very extensive nor very recent; still, I have used it in the kitchen garden here, and both as a mechanical agent on our heavy soil and as a manure the results were quite satisfactory. I have also used it with good results in Rhododendron culture. Since receiving your letter I have interviewed two of our best and most extensive farmers whom I knew used it largely. One of them always mixes it with straw manure from the local dairies, with excellent results with all kinds of farm crops. The other uses it alone, although he also uses some straw manure; but he says if he could get sufficient peat moss litter for his 400 acres, he would use nothing else. Both of these farmers pay about £3 10s. per acre, and they grow Potatoes extensively. I have had the opportunity of observing the operations of a market-gardener within the municipal boundaries of Edinburgh for over thirty years. This man grows vegetables exclusively, and uses no other organic manure than peat moss litter. He grows excellent crops of all kinds of vegetables, as he would require to do, for he pays £10 per acre for his land and has to pay the City rates.

CHARLES COMFORT.
Broomfield Gardens, Davidson's Mains, Midlothian.

I HAVE seen peat moss litter manure used largely, with very good results; in fact, I know a farmer who uses this in preference to any other manure for such crops as Potatoes, Swedes, Mangel Wurzel, &c., on heavy land. For my own part I would give preference to straw manure.

Royal Gardens, Windsor. JOHN DUNN.

I HAVE used peat moss litter manure from stables, where the horses are regularly hard fed, for several years in fairly large quantities, but mostly for top-dressing herbaceous and Rose borders, Begonias and, indeed, almost all summer-bedding plants, also for all sorts of fruit trees and bushes, and I think it one of the best manures for this purpose. I never now dig it in; the residue is usually raked off and burnt along with other garden rubbish. For kitchen garden purposes I think it inferior to straw manure, as on one occasion a very large proportion of my Potato crop rotted after an application of it dug in in the usual manner, and this, too, in a season when Potatoes did remarkably well under other conditions. I may add, however, that I used it for two years in succession on the flower garden beds, digging it in, without any bad results; but, as I have not continued to use it thus, I am not in a position to say how long it would take to prove detrimental to the occupants of the flower-beds.

THOMAS WILSON.
The Gardens, Glamis Castle, Glamis, Forfarshire.

- FORTHCOMING EVENTS.
- February 24.—Royal Horticultural Society's Meeting and Exhibition. Lecture at 3 p.m. on "The Uses of Explosives and of the Blow Lamp."

BOWLING GREENS.

THE game of bowls, the national game of Scotland, has made rapid strides in popular favour all over England during the last ten or fifteen years. There is ample evidence of this in our public parks and pleasure grounds, all the most enterprising of our municipal corporations providing greens, the number of which are

will materially assist in laying the turves level. To secure uniformity in the thickness of the turves, they must all be passed through a mould or shallow box. This is 1 inch, 1½ inches or 2 inches deep, according to the nature of the soil, and 1 foot square or 15 inches by 1 foot. Each turf is turned grass downwards in the box, beaten down to make it flat, and whatever soil and roots remain above the level of the mould is cut off with an old scythe blade, as shown in the illustration. By this means every turf is exactly the same size and thickness, and there are no broken corners. The turves must not be laid straight across the green, but from corner to corner, the join of two turves being in the middle of the one next to it, as the bricklayer lays his bricks. If this is not done, there may be ridges all down the green, formed where the turves join in rows.

A BOWLING GREEN IN THE MAKING. THE WORK MUST BE FREQUENTLY TESTED WITH STRAIGHT-EDGE AND SPIRIT-LEVEL.

being added to every year. It is also interesting to record that so popular is the game, the initial cost of construction is soon recovered by a small charge to the players. The charge made by one prominent corporation is one penny per half-hour for each player, this fee showing an average return of £40 per year for each bowling green maintained by that body. The first consideration is the selection of a site suitable for a bowling green. The position must be an open one, so that every portion of the playing pitch gets the maximum amount of air and sunshine. A full-size bowling green is 42 yards square. The piece of ground selected should not be much under 50 yards square, and fairly level. Greens half this width are sometimes made, when there are only a few players to cater for; but if the green is square, it permits of the play changing from the ends to the sides in alternate days or weeks, so that the ground is not worn in one direction. For the game of bowls it is more important than in any other sport played on grass to have a level surface. A perfect green should be as level as a billiard-table. Having understood this, it will be readily recognised how important every detail in the making of a green must be studied.

The initial outlay will depend largely on the nature of the subsoil. One that is very porous need not have any brick rubble put in for drainage, the layer of ashes being sufficient. The making of bowling greens on heavy clay soils entails much more work. The ground must be excavated to a depth of 15 inches; if waterlogged, pipes must be put in for drainage. Fill in to a depth of 6 inches all over the position of the green with brick rubble and clinkers. With rammers make this as firm as possible. Next spread 3 inches of fine ashes all over, placing on this 3 inches of good soil; this also must be made very firm, otherwise in a year or two it will sink and spoil the even surface of the turf. A thin layer of fine sand should be spread over the surface, which

the best month for sowing. Firms who specialise in grass seeds—Messrs. Carter, Raynes Park, and Messrs. Sutton, Reading, for instance—supply a special mixture for bowling greens, or a mixture may be made up of two parts of Crested Dog's-tail Grass (*Cynosurus cristatus*) and one part fine-leaved Sheep's Fescue Grass (*Festuca ovina tenuifolia*). The preparation of the green for seed-sowing is the same as for the turf, except that instead of the turf, 2 inches of fine mould should be spread over the surface.

At all stages in the making of bowling greens special and frequent attention must be paid to the levels, testing the work as it proceeds with a straight-edge and spirit-level. It is usual to have a ditch a foot wide all round a bowling green, with batten trellis-work in the bottom to catch the bowls when they roll off the green. Another familiar object beyond this on many greens is a raised bank 1 foot or 15 inches high sloping from the green. As an edging to the green, boards about an inch thick and 6 inches to 9 inches wide are placed in the ditch, sufficiently low for the thickness of the turf to rest on the top edge of the boards.

In a short article such as this it is only possible to touch on the main points in the making of a bowling green. Too much importance can hardly be attached to the use of the very best turf, and where this is prohibitive in price seed sowing must be resorted to. Constructed in such widely different localities and under varying conditions, these have much to do with the exact methods adopted by the green-makers.

ROSES ON WALLS AND FENCES.

WHEN quite bare, most of our walls and fences are somewhat unsightly. It also seems a waste to let such valuable space remain unoccupied. Few, if any, subjects could possibly furnish such walls with so pleasing a beauty as well-selected and judiciously placed Roses. I write the last three words with a real meaning; for how often do we find Roses placed to the very best advantage? In almost all cases the lower portions of our walls and fences are bare after the first year or two. Both this bareness and the lesser show of bloom that comes after the first early glut of flowers from the long growths of the previous season can be minimised by placing some of our free growers and bloomers between the taller-habited varieties.

For example, no Roses will do better upon a wall than Marie van Houtte, Catherine Mermet, Lady Roberts, Molly Sharman Crawford, Lady Ashtown, the white and pink Maman Cochet, Bridesmaid, and, in fact, numbers of our most beautiful Teas and their numerous hybrids, the mere names of which would occupy far too much space. Oftentimes, too, these free growers will cover a wall up to 10 feet and 15 feet. But my main object now is to point out their extreme usefulness, both as an aid to the better furnishing of the wall and to keep up a more continuous crop of blooms.

Last year I noticed some good examples of this combination of climbers and our extra free dwarfers growers. In one case the climbers had gone quite 25 feet or 30 feet up the front of a house raised upon a terrace. The sorts most used were L'Idéal (extra good for this), Rêve d'Or, Climbing Perle des Jardins, Reine Marie Henriette, Ards Rover, Lamarque, and that always useful Noisette, Mme. Alfred Carrière. Most of the dwarfers already named were planted at the foot and midway between the climbers. A few flowers were still in evidence upon the latter, while the lower plants were simply a mass of bloom. There is yet another advantage in these last, for they will throw many very useful late flowers after those in the open are past, the protection of the wall being just what is needed to develop the latest buds. There is little good in naming more varieties, but I would call attention to the need for more generous feeding

LIFTING THE TURVES. THESE MUST ALL BE UNIFORM IN SIZE AND OF THE FINEST QUALITY.

THE TURVES ARE PLACED GRASS DOWNWARDS IN A MOULD AND THE SOIL CUT OFF WITH AN OLD SCYTHE BLADE.

than our well-established wall Roses often receive. Because they have grown well, it does not mean they are in no want of this attention; rather the reverse. Oftentimes they are in a very narrow border, with a hard and uncultivated roadway or path at their foot. It is really astonishing to see how well many of our vigorous climbing subjects do in such positions. Wistarias, Magnolias, &c., as well as our Roses, thrive as well as could be expected if they have ample root-run and cultivation. We can help them a great deal by the extra free use of liquid manures, and should not be applied now, but in the summer and autumn.

When contemplating the planting of such strong growers, every advantage should be seized of making the surrounding soil as congenial and rich as possible; for we can so seldom get the opportunity again. The plants are generally put in as a permanency, and the walls themselves draw much moisture from the soil.

A. P.

HARDY CHINESE PRIMULAS.

THE Primulas from China are becoming of great importance to horticulture, and, numerous as they are already, it is certain that their numbers will be greatly increased, not only by new finds, but also by the hybrids which are being raised. It is indeed surprising to realise how rapid has been the influx of these Chinese Primulas.

Professor Bayley Balfour, in his paper at the Primula Conference of the Royal Horticultural Society in 1913, summarised the progress in a lucid manner. From his notes we gather that Lehmann's monograph of the family, published in 1817, did not include a single Chinese species. Twenty-seven years later, Duby, in De Candolle's "Prodromus," admitted only one Chinese species—the well-known greenhouse plant *P. sinensis*. Pax, forty-four years later, gave only thirty-seven Chinese species out of a total number in his monograph of the genus of upwards of 144. In 1905 the same authority described eighty-eight Chinese Primulas in Engler's "Pflanzenreich." At the last Primula Conference upwards of 140 Chinese species were recognised. Professor Bayley Balfour's classification is followed in these notes.

A considerable proportion of these Chinese Primulas are tender, or only half-hardy, in culti-

vation in this country, and I propose to deal at present with those which have proved fairly hardy. These alone form a valuable and numerous class, destined to occupy a prominent place in the gardens of the future. Taking them in alphabetical order, we first come to

P. angustidens (Franchet).—This is synonymous with *P. Wilsonii* (Dunn), and was introduced by Messrs. James Veitch and Sons of Chelsea under the name of *P. Wilsonii*. It was discovered by their collector, Mr. Wilson, in the Tali district of Yunnan, and has been in cultivation since its introduction in 1905. It has frequently been

sent out by nurserymen as *P. vittata*. It is closely related to *P. Poissonii*, and, like that species, belongs to the section Candelabra. *P. angustidens* is, however, a much better plant than *P. Poissonii*, as it is not only hardier, but is a better bloomer, although the flowers are smaller. In many places where *P. Poissonii* will not stand the winter, *P. angustidens* has proved entirely satisfactory. It is a strong grower, and under favourable conditions will reach a height of fully 2 feet, and will bear a number of lilac-purple flowers. The foliage is bright green and glossy. It is naturally a lover of moisture, but is not difficult to accommodate in a border or bog, among the moist grass, or in the lower parts of the rock garden. Its strong scent is a point in its favour, while the fact that it seeds freely will soon make it plentiful in cultivation. Cultivation: Good rich soil; damp situation; half shade.

P. Beesiana (G. Forrest).—This species, raised by Messrs. Bees from seeds sent by their collector, Mr. George Forrest, in 1908, appears to have been distributed about 1911. It also belongs to the Candelabra section, in which six purple-flowered species were recognised by Professor Bayley Balfour in his paper. It comes from the Tali region of Yunnan, and is a native of the moist meadows. It is a vigorous species, but is not so reliable in cultivation as its ally *P. Bulleyana*. It is said to reach as much as 3 feet in height when in congenial circumstances, but it is rarely seen of this stature. It bears whorls of velvety purple flowers, brightened by a yellow eye, which rise on a sturdy scape from amid the Primrose-like leaves. Some do not care for its colour, but it is likely to be of considerable value to hybridisers. Cultivation: Pure pulverised loam to which has been added some leaf-soil; half shade is best, but it does well also in full sun if soil is moist.

P. Bulleyana (G. Forrest).—Another of the valuable Primulas we owe to Mr. George Forrest and the enterprise of Messrs. Bees, Limited, is *P. Bulleyana*, which has come rapidly to the front as one of the best of the newer hardy Chinese

Primulas. It is now so well known that little need be said regarding its appearance. It has certainly come to stay, and whether as a distinct species or as the parent of a series of hybrids is bound to exercise an important influence upon the gardens of the future. It has handsome Primrose-like leaves, from among which spring tall scapes of flowers in whorls, rising in graceful tiers one above another. It lasts for a long time in bloom, and the effect of the flowers is practically indescribable, as they pass through various hues from their first showing colour till they fade off. The colours shown may be said to embrace scarlet, buff, orange and apricot, the final tint being a good yellow. This is a very easy Primula to grow, and may be suited either in any ordinary moist soil or by the side of a stream or pond, or in a moist meadow. It is vigorous and hardy, and seeds freely in the garden. Cultivation: Same as *P. Beesiana*.

Hybrids of P. Beesiana and P. Bulleyana.—From seeds of *P. Beesiana* × *P. Bulleyana* a race of pretty Primulas has been secured, these being of a coppery red and of better growth than *P. Beesiana*.

P. capitata (G. Forrest).—Authorities appear to agree that the Himalayan *P. capitata* (Hook.) is represented in China by several forms. Of these, *P. sphærocephala*, Balfour fil., and *P. pseudo-capitata* have been introduced, but are as yet little known. They bear a considerable resemblance to *P. capitata* (Hook.), and are characterised by the possession of the same globular heads of purple-blue flowers. From a garden point of view these may be classed with *P. capitata*, which is not generally a long-liver. They grow naturally in gritty soils and on grassy hillsides. *P. sphærocephala* comes from the Kari Pass in Yunnan, and *P. pseudo-capitata*, which was collected by Kingdon Ward for Messrs. Bees, Limited, and introduced in 1911, comes from Atuntsu in the same province. Cultivation: Good loamy soil in a shady position.

P. Clementinæ (G. Forrest).—This is a small plant which was introduced by Messrs. Bees, Limited, in 1908. It is more or less covered with farina, and the slender scape, considerably longer than the leaves, carries several lilac flowers at its summit. Cultivation: Loamy soil with the addition of a little coarse sand; half shade.

JOHN MACWATT.

(To be continued.)

LAYING THE TURVES WITH THE AID OF THE TURF-BEATER.

DAFFODIL NOTES.

Irregularity of Pot-grown Bulbs.—There is general chorus of complaint about the irregularity with which pot-grown stuff is flowering. In some way or another the season of 1913 affected the ripening of the bulbs. When I was in Holland in the early days of this month I saw an example of it at a small market-grower's at Beverwijk, where a fine healthy batch of Emperors were displaying this undesirable behaviour, some of the plants being almost in flower, while others were but half grown. Irregularity is a serious thing for those who cater for the cut-flower trade, as it means a much less number of boxes can be passed through the houses in the course of a season. The amateur who grows Daffodils in pots is not concerned with the question of profit, but he is, naturally, not over-pleased when he finds that in a potful of five or six, two or three bulbs have almost done flowering when the others are only just commencing. This year, at any rate, it is not the dealer or grower who is in fault, but our old friend the Clerk of the Weather, who evidently was not thinking of the forcing season when he was regulating affairs in the spring and summer of 1913. Coming from the general to the particular, I am wondering how far this abnormal year has upset my theory of how to produce good blooms early in the year. By this I mean blooms fairly in "character." Twelve months ago my dodge "worked," but is only "so-so" in its results this present season. I am not the only one who is experimenting in this direction, for at Hillegom I saw the practical outcome of another "dodge" to promote good early growth. Here the difference between the ordinary and the other was most marked. Of these more anon.

Some Good Varieties for Early February.

— With accumulated experience, certain varieties are beginning to stand out as good for early work in pots. Foremost among these I must place Fairy, a very free-flowering yellow belonging to Division I. Its prominent and distinguishing characteristic is the fine bold roll-back of its widely expanded trumpet. It is naturally a dwarf grower, but this is no detriment to its value as a garden plant—rather the reverse, as it affords variety in height in the bed and border, while under glass it is always sufficiently long for any practical purpose. A desideratum in these early days among Daffodils is variety. We have a good many yellows, but not many bicolors and very few red cups. Whites, if we may so describe Mrs. Langtry and Minnie Hume, are equally scarce. Fairy Queen, which one might call a clean-cut-out Mrs. Langtry, is altogether a most delightful and satisfactory flower; it "comes" easily and freely, and when fully developed is one of the Leedsis to which the adjective "petite" might

truthfully be applied. It is one of the whites of the future, or I am greatly mistaken.

In Silver Spur we have a fine large bicolor trumpet. Considering its price (about 2s. 6d. per dozen), I wonder it is not more known, for it supplies a want, inasmuch as it provides a contrast in form to the stiff and well-known Victoria. It has a large flower, quite as big as a Duke of Bedford, with a very refined-looking deep yellow trumpet and not at all a bad perianth. Only it is so very inapplicable to readers of THE GARDEN. I would have said it must have heard the old proverb about casting pearls before swine; it is so sparing with its blooms. It is not stingy like some, nor prodigal like others. One big bulb, one good flower, is its rule, and one which is seldom broken.

THE STATELY GALTONIA CANDICANS GROUPED IN THE BORDER FOR EFFECT IN LATE SUMMER.

Under bicolors I must just mention the cheap and pretty Queen Bess as an excellent incomparabilis (Division 2B) for pots or for growing *in extenso* for cutting. When we come to red cups, I am year by year getting more confirmed in the very high opinion I have formed with respect to the good qualities of Blackwell. My own two pots this year "were a treat," and would have done me credit at Birmingham. Alas! alas! the same money that can buy twelve fine bulbs of Golden Spur will only purchase one of Blackwell.

I am glad to find that early culture under glass is more and more occupying the attention of traders. The Royal Horticultural Society's

Forced Bulb Show in March seems to have reminded people of the potentialities of the Narcissus family as pot plants. Gradually the best are crystallising out, and doubtless more than two or three are experimenting as to the best means of producing good early flowers. The collection that I have already referred to at Hillegom belonged to the celebrated firm of Messrs. R. van der Schoot and Sons. In all there were forty-five varieties, most of them represented by two or three panfuls. The majority were their own Poetaz and trumpet varieties. Among the former, Sunset and Triumph were particularly good. As I saw Sunset it was a more effective flower than Jaune à Merveille, inasmuch as its cup is a deep orange, which is well set off by the pale yellow perianth. Fairy was splendid. Hoboken, which is a sort of small, rather deeper-coloured Golden Spur, very early and very free; and the sweet-scented Vanilla, with its wide-mouthed trumpet and somewhat spidery perianth, were both good, and are well worth growing under glass. Does not all this suggest a Daffodil house? What pleasure such a structure might afford us all through February and March! Then, when the Daffodils are over, it would just do for a collection of Darwin Tulips.

JOSEPH JACOB.

THE CAPE HYACINTH.

(GALTONIA CANDICANS.)

THIS noble border plant is now so often seen that it is cherished with the same feelings of respect extended to those flowers that have been grown for centuries in our gardens. To those who are not acquainted with the introduction of Galtonia candicans, it may come rather as a surprise to learn that it was introduced by one who died in the spring of last year. The introducer was Mr. Thomas Cooper, who spent much time collecting plants in South Africa. Another well-known plant for which we are indebted to him is Asparagus plumosus.

G. candicans is sometimes known under the generic name Hyacinthus, or by the popular name Cape Hyacinth. It is a bulbous plant belonging to the Lily Order, with fragrant, white flowers

from July till late September. The drooping flowers are borne on tall spikes 4 feet to 6 feet in height. It is well suited for planting in masses in the flower border, or for mixing with peat-loving shrubs which are not tall enough to hide the handsome spikes of bloom. Although it is a hardy subject, it is occasionally grown for the conservatory, where it is appreciated, as it makes an admirable pot plant. It is of easy culture, showing preference for a rich, leafy soil to which a fair amount of peat has been added. It may be grown from seeds, but this is tedious, as the seedlings take four or five years to flower. The more satisfactory way is to increase it by offsets from the bulbs.

THE LENTEN ROSES.

By reason of their purity of blossom and winter flowering the Christmas Roses stand alone in their season, those of the Lenten section are equally without a rival for quaint beauty and distinctive colouring at any time, and as such merit the attention of those who garden chiefly in the open air. It so happens, however, despite their many graces, their abundant flowering and simple cultural requirements, that these Lenten flowers, while prized by some, have never been greatly popular. Rather has it been left to the few who specialise in good things to take them upon their merits and make of them the success they deserve to be. Were the term "retiring" or "reserved" possible of application to a flower, then I would certainly say that these Lenten Roses merited some such a phrase, seeing that theirs is a beauty apart—something to be looked for—and not making for ostentatious display. Hence for those who see beauty only in gaudy flowers, these are not well suited. All the same, it is not too much to urge that, even without flowers, in certain localities and soils they would merit cultivation for their leafage alone. Lovers of shelter and appreciating the proximity of evergreens or shrubs to protect them from the biting winds of spring, this and a great depth of cool and, if possible, moist loam would appear to be among their chief needs. Shelter, indeed, if we would retain the winter beauty of their leafage till the arrival of the new, would appear more or less a necessity, though even this is modified by circumstances, particularly those of soil and soil moisture. Given the shelter of Hazel bushes, these plants, too, are very charming in the woodland, the same kind of shelter standing them in good stead when growing in lighter loams over chalk. Indeed, there would appear to be much in chalky loams to satisfy their needs, the cooling influences of stone and soil depth apparently suiting them as much as the lime, which they seemingly assimilate to their advantage. But they are not fastidious, and one may see them occasionally in perfection in the strongest of loamy soils. One item, however, is important, viz., that a considerable soil depth be assured, and certainly not less than 2 feet. In this connection mention should be made of their remarkable root activity, which, with its abundance, quite accounts for their somewhat voracious appetite. To some extent the great root system of these Lenten Roses finds its parallel in the fine leafy bushes above the ground, which could not receive adequate support otherwise. Hence it should be clear that soil of a generous character and depth would be much to their liking, and if to this be added light shelter, then, I think, we have presented in nutshell form their chief cultural requirements.

To those seeking to increase them by division—an operation that may be performed in autumn or spring—I would suggest the former as the best season, to save conflict with the flowering period and to enable the plants to become partially established before the coming of the new leaves. Lenten Roses are among those herbaceous perennials which I refer to as "perpetual rooting"; hence they may be planted or transplanted over a somewhat extended period of time. The Christmas Roses, on the other hand, are distinctly periodical in root production; hence, for these, if we would have of their best, I have unhesitatingly set apart August and September as *the only rational planting season of the year*. The genus *Helleborus* is the only one I recall at the moment where these differences of root production are so obvious, which to the observant gardener should give food for much thought.

THE RED-FLOWERED PLUMBAGO.

In most private gardens this beautiful plant, *Plumbago rosea*, is usually grown in pots, and certainly it is a most useful subject for dotting about among Palms and Ferns in a large stove; but, I think, to get the best results it should be planted in a bed or border. Evidently this plant enjoys a fairly free root-run, for it produces much stronger foliage and flower-spikes when planted in a narrow border and trained up the back wall of a warm house.

Here the wall of the stove is completely covered with it, and such has been the quantity of flower-spikes produced that we have been able to decorate several large dinner-tables with it this winter, and there are still a large number of spikes just opening their flowers. The plants are growing in a narrow border about fifteen inches wide

FLOWERS OF THE LENTEN ROSE, *HELLEBORUS ORIENTALIS*, A PLANT FOR THE SHADY BORDER.

A primary attribute of not a few Lenten Roses is the profuse spotted character of the flowers, some of which are very beautiful, while others, of rich or deep plum or purple colouring, appeal to a large number. Unfortunately—or otherwise—the flowers are not of great service in the cut state unless the stems are split longitudinally, and, even so, they never appear quite happy; hence their best place is the garden where they associate well with plant and shrub in woodland and other places. Some good varieties are *antiquorum* James Atkins, rose pink; *a. Willie Barr*, also rose coloured; *orientalis* (see illustration); *colchicus* and *c. magnificus*, plum and crimson coloured respectively; *Apotheker Bogren*, crimson-purple; *gutta tus*, white, spotted crimson; and *g. sub-punctatus*. These Lenten Roses are free seeders, and readily submit to cross-breeding.

E. H. HENRI

and the same in depth, in fibrous loam, with the addition of a 6-inch potful of bone-meal to each barrow-load of loam. Beyond heavy syringing during the summer months and an occasional pinching of the growths to ensure an even distribution of the flowers, the plants have received no special attention. It is necessary to pinch the growths at least three times, for, if left to grow as they like, all the flowers will be at the top, which detracts from the appearance of the plant when grown on a wall. A sharp look-out must be kept for thrips, which play havoc with the foliage if allowed to get a hold. An occasional syringing with Niquas is a good preventive of this pest. After the plants have finished flowering they are cut down to within a foot of the ground, the border top-dressed and kept lightly drier till growth commences in the spring.

Perhaps it will interest some of your readers who have dinner-tables to decorate to know that a table much admired here was done with *Plumbago rosea* mixed with sprays of *Deutzia gracilis*. This makes a very graceful combination, and it lights up well.

JAMES G. BESANT.

Oak Park Gardens, Carlow, Ireland.

VIOLETS IN THE OPEN GARDEN.

ONE of the prominent flowers of the season is the popular Violet, and many gardeners go in for its culture somewhat extensively. Encouraged and protected by glass, in one form or another, Violets can be coaxed to do marvellously. They are, however, eager enough to flower in the open, and will do so under almost any conditions so long as the weather remains mild. Should hard weather be encountered, however, many growers

NEW AND RARE PLANTS.

Iris Cantab.—We believe this beautiful early bulbous variety, which, presumably, is of the *reticulata* set, was raised by Mr. A. E. Bowles, and it is certainly one of the most charming of its class. The fragrant flowers are singularly compact, and nearly six inches high as shown. The standards are pale blue, falls pale violet, with narrow golden crest. From Messrs. H. Chapman, Limited, Rye. Award of merit.

Rhododendron moupinense.—This new Chinese species was exhibited under the provisional name of *warleyense*, a little 6-inch-high bush, having three large white flowers of about two and a-half inches across, in which were seen deep chocolate-coloured anthers. The blossoms have a horizontal inclination. The Box-like leaves are obovate, entire, about one and a-half inches long, and nearly

C. J. Phillips; *Odontioda Diana* variety *Glad*, from Messrs. J. and A. McBean; *Cymbidium Schlegelii* Southfield Variety, from Mr. W. Butler; and *Odontioda Lucilia*, a mauve and purple variety with dark blotches, from Messrs. Charlesworth and Co.

The foregoing plant novelties were shown before the Royal-Horticultural Society on the 10th inst.

SEASONABLE NOTES ON CARNATIONS.

BORDER Carnations are not yet quite extinguished by the immensely popular Perpetuals, and a very nice way of growing a selection is to place them in pots—7 inch for preference—in the South, standing them in the open till the flowering stage and housing them during that period. In the North it is better to grow them the whole time under glass. The plants do better and flower a few weeks earlier than those growing in the open. *Lady Hermione*, can be kept in health only by pot culture, and, as a rule, the lovely flakes, bizarres and white and yellow ground Picotees are easiest to preserve in robust health when grown in pots, but, of course, without being coddled. A compost suited to soft-wooded plants generally suits border Carnations equally well, the one thing they and all sections of Carnation abhor being deep potting.

For Outdoor Cultivation.—I need not labour to prove the extreme hardiness of the Carnation, and only remark that this physical quality permits of those which have been wintered in pots to be planted in beds and borders in early spring as soon as the soil is in a fit condition to work. Those planted early in the year are invariably superior when in flower to those kept on till March or April. If it is not possible or convenient to plant now, the plants should have manure to keep them from becoming more or less starved. Plants rooted from cuttings late in autumn are not to be despised, such a free-flowering variety as *Raby*

RHODODENDRON MOUPINENSE, A NEW DWARF HARDY CHINESE SPECIES WITH WHITE FLOWERS.

leave the beds to look after themselves; whereas, if given a little care while such weather lasts, which is generally only for a few days, the roots would more than repay for the trouble in the extra flowers they would then produce. Violet-beds should always be so situated as to be somewhat protected from the keen winds, and, of course, replanting should be done frequently enough to ensure the crowns being always full of vigour. From the start of blooming to the finish in the early spring it pays to give outdoor Violets a light dressing of Peruvian Guano from time to time. If the weather is mild, the guano may be applied once a month; but if there is much hard weather, once in six weeks will be sufficient. During hard frost give the plants protection, by night at any rate, placing a light frame of lath over them—to prevent crushing—and covering with mats or anything else that comes handy. By following these hints open-air Violets will give satisfaction.

J. T. B.

an inch broad. The exhibited example was said to be about five years old; hence might be of the greatest value in the rock garden. The species is said to be quite hardy. From Miss Willmott, Warley Place, Essex. Award of merit.

NEW ORCHIDS.

The number of Orchids to gain distinction was even greater than usual. Sir Jeremiah Colman, Bart., gained a first-class certificate with *Dendrobium Lady Colman*, a magnificent hybrid of purple and velvety maroon colour. Baron Schröder gained a first-class certificate for *Cypripedium Pyramus* and an award of merit for *Cattleya Trianae* Mr. de B. Crawshay. Awards of merit were granted to the following: *Cymbidium gottianum* Westonbirt Variety and *Odontioda Margaret* Westonbirt Variety, both from Lieutenant-Colonel Sir George Holford, K.C.V.O.; *Cattleya Trianae* Mrs. Phillips, shown by Mr.

Castle, propagated in that way, giving abundance of bloom till quite late in the year, and for that reason stock from cuttings is more desirable for use in mixed flower borders than that from layers. Autumn-planted layers will now appreciate a dressing of soot, which, besides acting as a slow stimulant, keeps birds from pecking the leaves.

Malmaisons.—Plants which have been wintered in 3-inch or 4-inch pots are ready to transfer into others 6 inches or 7 inches in diameter. I now grow very few plants, but at one time I preferred to pot them on in autumn into 6-inch pots, and the strongest of these, being shifted at this season into 8-inch and 9-inch pots, were induced to grow on continuously till the next autumn, when a crop of bloom was secured off the side shoots. Old plants not to be given a shift must have manurial aid and, as occasion permits, be restaked, weakly shoots cut away, and leaves that have recently perished removed.

REPOTTING A YOUNG PERPETUAL-FLOWERING CARNATION: A, DEPTH TO REPOT; B, WHERE TO PINCH OUT THE YOUNG GROWTH.

Perpetuals.—Young plants recently placed in 2½-inch pots fill the latter with roots in the space of a few days, and must then be transferred to larger ones—either 3-inch or 4-inch—a check from underpotting at this stage being inimical to the whole future of the plants. The Perpetuals succeed in such a variety of soils that no one need hesitate to attempt their cultivation on account of soil, the chief point being to make it open enough by means of lime rubble and sand, if too close, to preserve it in a porous condition. Animal manures should be employed with the utmost caution, but a little artificial manure is of benefit in strengthening the plants. There is some diversity of opinion regarding the temperature which the young plants should have, some growing them warmly with slight ventilation. I rather prefer to grow them right on with free ventilation, and not much heat other than that derived from the sun. Growth is slower at first, but in the long run the cooler treatment is the more successful. I must not forget to note the serious effects that follow deep potting, and to this may be traced the deaths that occur in some collections.

Flowering stock is now awakening to fresh vigour after the weary winter, and will now respond to Nature's advances if frequent applications of manure are given. Plants in 5-inch and 6-inch pots may be repotted into those two sizes larger, and the whole examined for withered foliage. Stems from which the flowers have been cut still further shorten to well-placed young shoots, and tie all young shoots loosely but securely in before they lean over laterally. Seeds of Perpetuals should be sown at once, using very friable soil and germinating them in a temperature of 60° to 65°, in which the seedlings will very soon appear, after which transfer them to a lower temperature. Nothing is gained by sowing border Carnations so early.

R. P. BROTHERSTON.

DESIGN FOR A SMALL FRONT GARDEN.

I AM building a small villa for myself, and should feel favoured if you would kindly give me your views of the best way to set out my front garden. There is about twelve inches of good top soil; after that clay. Roses do very well. Would a sort of Dutch garden do, with Roses and old York paving?

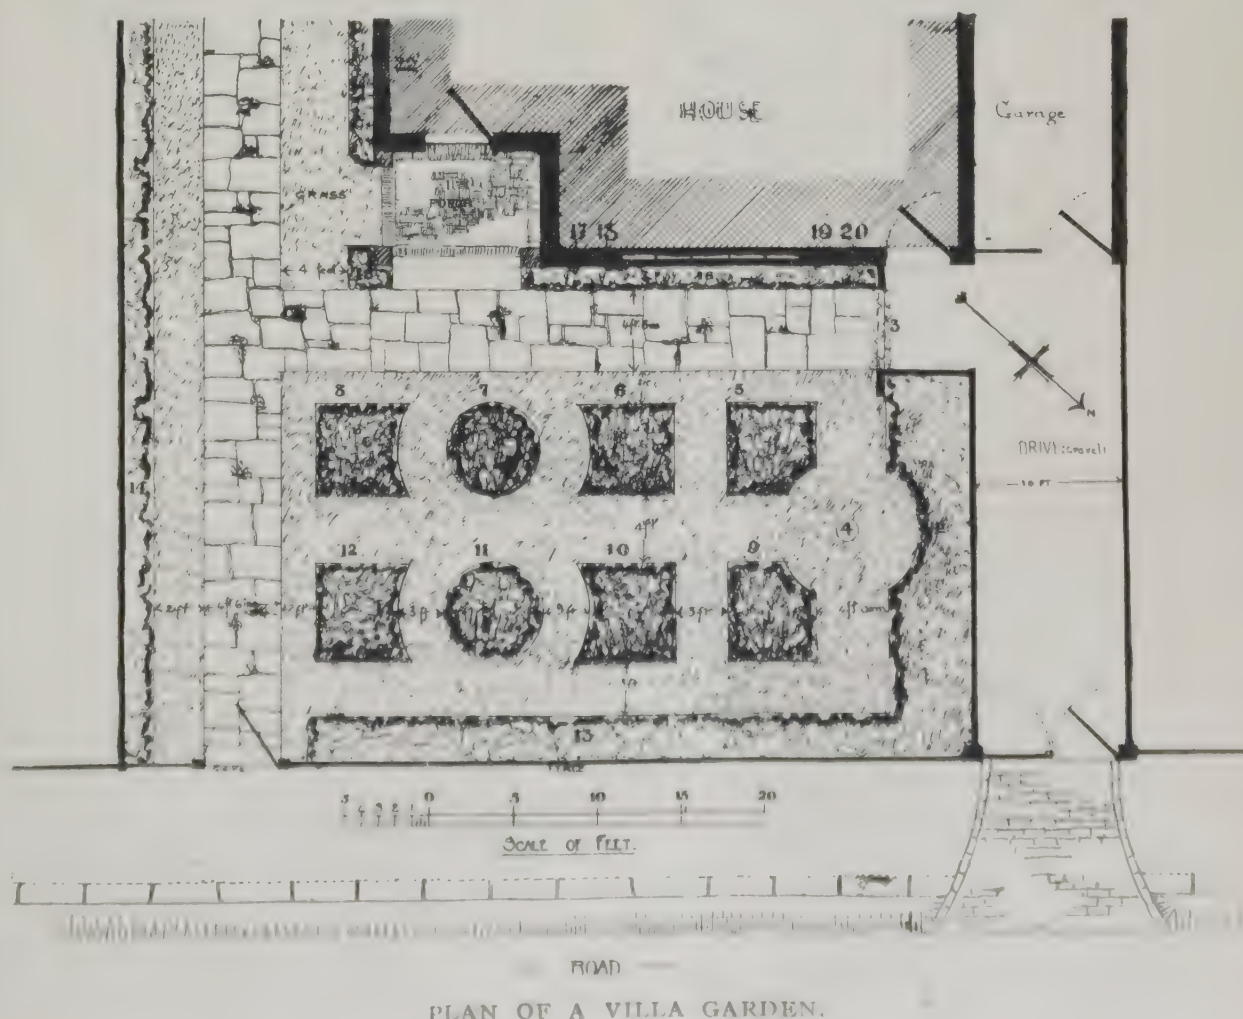

T. B.

[It is assumed that the owner of this villa does not wish to approach the front door by a road wide enough for vehicular traffic, and therefore has a considerable space to devote to gardening on this side of the house. To use his own words: "There is about twelve inches of good top soil; after that clay. Roses do well." Certainly, then, he should use Roses largely in the planting, and the design given in the accompanying illustration has been prepared specially with this in view. If the beds seen in the plan are too simple in outline, remember that Roses cannot be used successfully in beds of fancy shapes, because they will not fit to the beds when they grow.

Such Roses as are included in the planting scheme should have the longest possible period of flowering. Dwarf Roses only should be used in these beds, as the area is not large enough to overcome the aggressive appearance of standards. The design for a garden such as this cannot be too simple, and the only hard paths introduced should be between those points that *must* be approached. Roses, principally Hybrid Teas, that give the longest possible period of flowering are eminently suitable. It is better, however, to make provision for the introduction of a few other plants, as Roses by themselves are not attractive at certain seasons of the year.

1. Could be either trellis covered with pink Roses and pale blue Clematis, or an evergreen hedge to screen off the approach to garage.

2. This border could be filled with pink China Rose Hermosa and clumps of Lavender, with white Madonna Lilies in the corners.
 3. Trellis arch to screen off tradesmen's door.
 4. Lead figure or vase.
 5. Rose Caroline Testout, carpeted with Viola Maggie Mott.
 6. Rose Richmond and dark purple Viola.
 - 7 and 8. Various good Roses of similar habit of growth as desired, principally cream and pink shades, and cream Viola as edging or carpet.
 9. Rose Mme. Abel Chatenay and Viola Maggie Mott.
 10. Rose General Macarthur and dark purple Viola.
 11. Rose Hugh Dickson and purple Viola.
 12. Rose Warrior and purple Viola.
 13. This could either be Rose Fellenberg, allowed to grow into a hedge, or, if a solid fence is used on which climbers could be trained, it could be filled with the choicest and best Roses that do not make rampant growth; just a collection of "gems," the aspect being south-west.
 14. Repeat No. 2, training the longer growths of the China Rose against the fence.
 15. Wistaria sinensis or W. multijuga, and Jasminum officinalis major to train over porch.
 16. Border for bulbs, Wallflowers and a few summer-flowering plants; this border to be changed with the seasons and always kept bright. Also plant the following creepers to train on house;
 17. Clematis Nellie Moser.
 18. Jasminum nudicaule.
 - 19 and 20. Climbers to taste, remembering the aspect is north-east.
 21. Flower border, say, Nepeta Mussinii and pink Antirrhinums.
 22. Magnolia grandiflora trained on house.
- The grass area should not be an inch less than shown on plan. The paved walk from the front gate should lead to some definite feature in the gardens beyond.—ED.]

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Late Vineries.—All late vineries should be shut up and started gently by March 1, as late varieties of Grapes require a long season to bring them to perfect maturity, and unless they are thoroughly finished by the end of September, the prospect of keeping them in plump condition through the winter will be much reduced. Very little fire-heat will be necessary for some time, as the temperature should not exceed 50° by night and 65° by day.

Early Peach-House.—The growth on early trees will be sufficiently advanced to require frequent syringing with clear soft water, to keep aphid and red spider in check. The final disbudding may now be accomplished, leaving a well-placed shoot as near the base of last year's growth as possible; another may be left between the base and the terminal bud if space will permit, but nothing should be left beyond what can be conveniently tied in without overcrowding the tree. Very little thinning of the fruits should take place before the stoning period is over, and then select the fruits on the upper side of the branches, so that they may be fully exposed to the sun. Attend to the disbudding of successional trees, removing a few buds from each shoot at a time, so that no check in the growth may take place.

The Orchard-House.—Give plenty of air to Apple and Pear trees which are in bloom, examine the pots twice daily, and give a good soaking of clear water when necessary. As soon as the crop is set, weak liquid manure may be given once or twice a week. Syringe the trees early in the day and avoid fire-heat as much as possible.

Plants Under Glass.

Chrysanthemums.—The earliest batch of plants will now be well rooted in small pots, and ready for potting into 6-inch pots. The soil may consist of two-thirds turfy loam and one-third leaf-soil, with sufficient old lime rubble to keep the soil porous. The pots must be clean and the soil made firm about the roots; replace the plants in a cold pit on a bed of ashes. No fire-heat should be applied if sufficient covering can be found to exclude frost. The pit should be kept closed for a week or more until the plants are established, after which air should be admitted in increasing quantities until the lights are removed on fine sunny days, the aim being to produce sturdy, short-jointed plants, and consequently crowding must be avoided.

Seed-Sowing.—Chinese Primulas for November flowering should be sown now. The soil may consist of fine sifted loam and leaf-soil in equal parts, with sufficient rough sand to keep the soil from becoming sour. Cover the seeds very lightly with fine sandy soil and place them in a temperature of 60°. If not already done, a sowing of Balsams, Celosia and Cockscombs should be made, also of Streptocarpus.

The Flower Garden.

Pentstemon Plants which were struck in cold pits during September should now be carefully potted into 3-inch pots and placed in a similar pit quite near the roof glass. Let the pit be kept closed until the roots are well established, after which air should be freely admitted until the plants are ready to put out about the first week in April.

Antirrhinums.—If these were raised from seeds in the autumn, they should now be ready for planting where they are to remain, and if lifted with a good quantity of soil about the roots, they will commence to flower early in the season and continue for a considerable time. It is not too late to raise Antirrhinums from seed for flowering in August and September.

The Pleasure Grounds.

Pruning Shrubs.—If not already done, this work should be finished with as little delay as possible, and the requirements of each individual plant must be considered as the work proceeds. A strong pruning-knife is the best implement for the purpose. Specimen Hollies should be carefully pruned, and, where the branches have become too thick and crowded, a few may be carefully cut and drawn out so that the plant may present a more natural appearance. Avoid pruning

Laurels and other large-leaved shrubs with shears, as by this means many of the leaves are cut and the plant made to present a most unnatural appearance.

The Hardy Fruit Garden.

Protecting Early Flowers.—In some districts Apricot flowers will soon require protection from frost, and this is best accomplished by thin canvas blinds, which should be drawn up every morning and run down again in the evening. Old fish-nets may also be used for the purpose, but care must be taken that neither covering comes in contact with the flowers.

Strawberry Plants for autumn fruiting which have been wintered in small pots may now be planted on a well-prepared border with an eastern aspect. These plants do not grow so large as summer-fruiting varieties, therefore it is not necessary to plant them so far apart. St. Antoine de Padoue is one of the best for this purpose, and continues to produce a supply of nice fruit until quite the end of October. Seeds of alpine Strawberries may be sown now for autumn fruiting.

The Kitchen Garden.

Parsley.—The main crop of Parsley may now be sown as soon as possible. An open position should be chosen for the purpose, allowing 18 inches between the rows. Cover the seeds lightly, with fine soil. Young seedlings raised under glass should be planted in a warm position as soon as large enough. This may prove a valuable crop in the early summer.

Cauliflower Plants which have been grown in cold pits during the winter should have the lights removed every morning and replaced again at night, in order to produce good stocky plants for planting early in April. Further small sowings of Cauliflower should be made from now till the middle of May. Magnum Bonum and Dickson's Great Dane are splendid varieties for sowing now.

Leeks.—The principal sowing of Leek seed should be made without delay. A good rich border should be chosen for this purpose, and the seeds sown in shallow drills a foot apart.

Chervil.—Where this is in demand, a small sowing should be made every ten days, and during the summer the sowings should be more frequent. *Royal Gardens, Windsor.* JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery.—Those who are expected to have Celery towards the end of August will require to make a small sowing now. Sow the seeds thinly and place them in a temperature of about 60°. When they have germinated, see that the seedlings do not suffer for the want of water at the roots, as this would assuredly cause them to bolt later. Perhaps there is no crop that will resent neglect in this way more than Celery. The plants will require careful attention right on till planting-time.

Asparagus.—Should the weather be favourable, Asparagus-beds ought now to receive attention. Have all weeds cleared off and give a good dressing of rich manure. On established beds especially this will be all that is necessary. Where it is intended to make a new plantation, the ground should be trenched to a depth of 3 feet, adding some well-rotted manure and burnt refuse as the work proceeds. Leave the whole in a rough state till the end of March, or in cold districts till the second week in April, which will be quite soon enough to plant.

Potatoes.—Early Potatoes may now be planted out of doors, say, on a narrow border at the foot of a south wall. Any of the early varieties now on the market may be planted, as, being against a wall, I find they are easily protected on the approach of frost or very cold weather.

Turnips.—Seeds of Early Milan Turnips may be sown in rows on a warm border. The Turnips, of course, must be used when quite small, otherwise they would assuredly run to seed.

The Flower Garden.

Sweet Peas.—Where Sweet Peas are intended to be grown in a row, it will be well to throw out the trench now, say, to the depth of 2 feet or so.

Leave this trench open until planting-time, when the soil will be pulverised and mellowed by the weather. Previous to planting, this should be filled in, with the addition of manure and fresh soil.

Anemones.—These beautiful perennials are becoming more popular than ever, and will well repay any little extra trouble one may take in their cultivation. To grow them well I find they require to be liberally treated. The present is a good time to plant. The ground, of course, should have been previously dug and well manured. Seeds may also be sown now of the beautiful St. Brigid variety. These will bloom towards the end of September. Being very slow in germinating, I find it best to sow in boxes and place them in a cold frame. They require careful handling until planted out.

Polyanthuses.—Now will be a good time to make a sowing of Polyanthuses; at least, we seem to get better results from this sowing than from one made out of doors in May or June. Sow in pans and prick out the seedlings when ready; these should make fine plants for putting out in the autumn.

Lobelia cardinalis.—It is very doubtful if this attractive plant receives the attention it deserves. Last season I saw a charming bed of East Lothian Stocks, with Lobelia cardinalis used as dot plants. As seen from a distance the effect was very striking. To produce such an effect the Lobelia should be divided now, potted, and brought on very steadily. If placed into a larger size pot before planting, so much the better. From seed sown now very good plants may be had by September.

Cannas.—The old stools should now be brought from their winter quarters, placed either in pots or boxes, and brought on gently in a moderate heat. Where it is intended to increase the stock, the old stools can be divided and potted up singly. Harden them off gradually, and see that they are not put out of doors until all traces of frost have disappeared.

Plants Under Glass.

Achimenes.—These beautiful stove plants, which seem almost indispensable for adding a little colour during the summer, should now receive attention. Shake them out and place them in shallow pans or boxes filled with sandy soil, say, about an inch apart. When they have made about two inches of growth, they may be potted or placed in hanging baskets. In the latter I find they are most effective. During the growing season they should be constantly syringed to ward off red spider, to which they are very subject.

Chrysanthemums.—From now till the beginning of March will be a good time to put in the main batch of bush Chrysanthemums. As the cuttings on the old stools are growing freely, care must be taken to select only sturdy shoots, and do not root in overmuch heat.

Begonia Gloire de Lorraine.—Plants that were cut back early will now be pushing up young shoots. They may be taken off and rooted where they can have a little bottom-heat. Plants that bloomed later should be cut back and syringed frequently; these will supply cuttings later.

The Hardy Fruit Garden.

Spraying with Winter Wash.—Should this most necessary work not have been done earlier, no time should be lost in going over the trees. To destroy insect-life there is perhaps nothing better than caustic alkali, and, like all other operations of this kind, it must be done thoroughly, so that every part of the tree is treated. Great care must be exercised to protect the hands and clothes, as this solution is extremely injurious to both.

Arsenate of Lead Wash.—It is a good plan to spray trees and bushes with this solution just as the flowers are opening, and again when the fruit has set. Arsenate of lead can now be had in paste form, and if used according to the directions, there need be no fear of doing damage.

Brambles and Loganberries.—These may now be planted and treated in the same way as Raspberries. Fruiting canes may now be tied up, and remember that there is nothing gained by crowding them together; in fact, when trained too close, it is almost impossible to get among them to pick the fruit. HARDY CHRYSANTHEMUMS FOR FLOWERING IN NOVEMBER.

THE note by Miss G. Jekyll under the above heading in *THE GARDEN* of January 10 is most opportune. There are now a great number of beautiful Chrysanthemums that flower very satisfactorily outdoors during September and October, and the development of this section has been quite remarkable in recent years. I am quite in agreement with Miss Jekyll as to the value of those that come into flower in November, when outdoor flowers are so scarce; and the getting together of other varieties than those named in the note in question should not be a very difficult matter. The three varieties mentioned by Miss Jekyll are among the oldest now catalogued by the Chrysanthemum specialist. I cannot trace the date of the introduction of Emperor of China (syn. Cottage Pink), which I have seen luxuriating in cottage gardens in my autumn rambles through the country; but the variety Julie Lagravère, a dark crimson-red sort, was introduced by the late J. Salter so long ago as the year 1859. It is quite remarkable how well these old sorts retain their vigour. The foregoing are not large Pompons, but reflexed kinds. Sœur Melanie, raised by Lebois in 1869, is generally recognised as a hybrid Pompon, and is classified as a Pompon by the National Chrysanthemum Society. It is indeed a beautiful plant, and is more appreciated because it comes into bloom just as the plethora of the early flowering kinds is coming to a close.

In reply to the question raised, "Are there any more of this large Pompon class?" I am pleased to name a few varieties that are but very slightly known by the present race of growers. The Christine family is excellent for this purpose, and is represented by Golden Christine (golden bronze), Peach Christine (peach colour), Pink Christine (pink), Primrose Christine (primrose) and White Christine (white). These varieties have been in cultivation for many years, which speaks volumes for their vigorous and sturdy constitution. The plants come into flower during November. Dr. Sharpe, introduced in 1866, is a good rich purple magenta flower, and the plant is dwarf. The flowers, too, are fragrant. King of Crimson, another November-flowering variety, yielding large, full flowers of a rich crimson colour, is quite good and the plant is dwarf. This variety was introduced by the late J. Salter in 1845. Progue is another sweet-scented sort, of a rich amaranth colour. Some of the plants do exceptionally well against walls having a warm aspect. The foregoing are all reflexed kinds, and are larger than the series of Pompons I am now about to describe.

As far as I am able, I will arrange the Pompons in the order in which they bloom. A variety that has given me more than ordinary pleasure in the past is Lizzie George. It is a hybrid Pompon of a rich golden yellow colour that is in good form from the middle of October till the middle of November. The plants are a mass of glorious blossoms, and attain a height of not more than 2 feet. It is the best variety I know for the period. Crimson Précoce is a beautiful branching plant, evolving dainty, bright crimson blossoms in late October; height, 3 feet. Mlle. Elise Dordan, an ideal Pompon of a silvery pink colour, is very pretty

for late October and early November displays, and during the same period Mme. A. Colmiche, a reddish orange, is very useful; height, 4 feet. About the same time Sœur Melanie would come into flower. An excellent companion to the last named is President, a showy, bright rosy purple variety that is very popular in cottage gardens in this neighbourhood; height, 3 feet. For November flowering the following varieties will provide an interesting series of reliable plants: Mrs. Bateman (a large orange brown, dwarf), Rosinante (1856, blush rose, dwarf and fine), Nelly Rainford (buff yellow, sport from the last named), Osiris (rosy purple, shaded and tipped salmon), Prince of Orange (a fine, light orange amber coloured flower), Rose d'Amour (a pleasing rose-coloured sort), Florence Carr (a deep bronze variety, little known, but very attractive), William Kennedy (a rather large crimson amaranth flower of great beauty), and William Westlake (a beautiful canary yellow sort, sometimes suffused red, good habit and free flowering).

There are two families of exceptionally bushy, free-flowering dwarf Pompons that make very attractive bushes. One is the Cedo Nulli, represented by white, lilac, and golden varieties, and the Trevenna family, in which there are golden, rose, and white kinds, all most interesting. Two miniature-flowered varieties that should not be omitted are Snowdrop (white) and Primrose League (primrose). The flowers of these two sorts are of exquisite shape, and are freely evolved in very handsome and attractive sprays in the latter half of November. I could mention others that, I fear, are not now in general cultivation; but I have little doubt that the varieties enumerated will provide a welcome display outdoors later than usual, should the weather be kind and sheltered quarters be provided.

Highgate, N.

D. B. CRANE.

POTATOES SUITABLE FOR PLANTING ON INFECTED PREMISES.

THE Board of Agriculture and Fisheries desire to remind all occupiers of premises declared infected for the purpose of the Wart Disease of Potatoes Order that it is illegal to plant any Potatoes on such premises unless a licence has previously been obtained from an Inspector of the Board or of the local authority. The penalty for any contravention of the Order is a fine not exceeding ten pounds.

Such licences can, however, as a rule be obtained on application to the Board by any occupier who undertakes to obtain from a reliable dealer one or more of the varieties of Potato referred to here, all of which have been tested, some of them for several years, and have been found to resist wart disease under ordinary circumstances.

Should any occupier have any difficulty in finding a Potato dealer who can supply the variety he wants, the Board will, on application, send a list of dealers who have undertaken to stock these Potatoes, with a statement as to the varieties which each is able to offer.

Milecross Early.—White, round, not liable to ordinary Potato disease (Phytophthora), matures rapidly, haulm strong and quality good.

Conquest.—White, round, heavy cropping, second-early Potato of good quality; must be

earthed up high, as tubers are produced near surface.

Jeanie Deans.—A fine oval Potato with strong haulm and white flower. Crops heavily on light, rich soils. Stocks of this variety are not large.

Dobbie's Favourite.—A second-early, round in shape, white flower; an excellent Potato when well grown.

Abundance.—A well-known heavy cropping, late variety, oval in shape, of good quality, rather liable to ordinary disease; white flower.

Sutton's Supreme.—A second-early of pebble shape, white flower, suited to garden cultivation.

Great Scot.—A very good second-early; white and round, eyes rather deep; haulm robust; a very heavy cropper under good cultivation. Quality excellent; flower, white.

Schoolmaster.—A second-early, white-skinned and round; crops well, but is liable to ordinary disease. Not a good keeper.

Crofter.—A late, oval Potato of good quality; liable to ordinary disease. Flower, white.

Culdees Castle.—A pebble-shaped variety, not quite so strong in the haulm as Crofter, and liable to produce more seed size tubers on light soil. Does well under garden cultivation. Flower, white.

White City.—A late, kidney-shaped variety. A fine Potato for garden cultivation, but not a heavy cropper. Under high cultivation tubers are frequently hollow. Of first-rate quality. Flower, lilac.

Provost.—A late, white, round Potato possessing strong haulm and white flowers; well suited to garden cultivation. "Seed" should be changed every second year.

The Admiral.—A late variety, white-skinned and round. Haulm medium, a heavy cropper and good disease resister. Quality excellent. Flower, white.

Irish Queen.—Tubers round, eyes rather deep, haulm strong. Excellent cropper. Keeps late into season.

St. Malo Kidney.—Tubers coarse, kidney-shaped. Haulm robust. Not a good keeping variety.

King George V.—An elongated oval tuber, skin netted, eyes shallow, haulm strong. An excellent cropper. Quality moderate.

Davie's Laird.—Roundish tuber, flesh white. A robust variety that crops heavily on well-prepared medium loams. Quality excellent.

Flourball.—Well-known late variety, round and pink-skinned. Eyes rather deep, haulm straggling with bronzing on stems when exposed. Quality very good; flower, white.

Golden Wonder.—A late, white-fleshed kidney with yellowish brown tinge on skin. The "seed" should be a good size, and if unsprouted should be planted before the end of March, as the variety requires a long growing season. Liberal manuring is essential, and in gardens bastard trenching is recommended. It is possessed of excellent quality, and is one of the best late keeping Potatoes. Flower, mauve, tipped white.

Peacemaker.—Is similar to Golden Wonder.

Langworthy.—A late, kidney-shaped Potato possessing white skin and flesh. Tubers that are fully developed may generally be recognised by the characteristic tapering "heel." Quality excellent. Same treatment required as for Golden Wonder. Flower, mauve, tipped white.

What's Wanted.—Shape not so constant as in Langworthy. In other respects very similar.

N.B.—The last four varieties mentioned are, relatively speaking, light croppers, but they are

probably unsurpassed as resisters of ordinary Potato disease.

This list is not exhaustive, and there are several other varieties which are resistant. They are not quoted, as the supply of Potatoes of "seed" size is believed to be small.

PRACTICAL HINTS ON AURICULAS.

THE seasonable notes on Auriculas appearing month by month in THE GARDEN are much appreciated by Auricula-growers. The writer of these, in his last notes (page 67, February 7 issue), says: "Should the weather keep open and mild, the plants will be very active at the roots." At the time I am writing, all this has taken place, and the plants are passing from their winter rest to the period of their greatest activity, the new growth is pushing up, and, as it develops, the enthusiasm of the Auricula-grower is fanned into full flame again. What pleasure this gives to the ardent Auricula man as he visits his frames during the early spring months! To see the close, hard crown of the plants gently unfolding, displaying bright, fresh leaves, some green, others green with a delicate edge of white meal, some so covered by the meal that they appear to be grey and others quite white, is a pleasure that can only be appreciated to the full by the lover of these chaste plants who has cared for them since repotting-time some seven or eight months ago—months of loving care and attention, watering as needed, shading from the heat of the summer sun, keeping down the attacks of aphids and, later, the removal of withered leaves and transferring the frames to a sunny situation for the winter.

The full reward for this care is about to be reaped as the plants develop into full and mature growth and bloom. My appreciation of the Auricula is almost as great during March and early April, when it is unfolding its leaves and showing its bloom-truss in the heart of the plant, as it is in late April and early May, when in the full glory of its chaste and varied coloured blooms. At this time of year the keen grower is not likely to neglect his plants.

Top-dressing.—I agree with the writer of seasonable notes that top-dressing as practised by the growers of years ago—the taking away of an inch or so of soil and replacing by fresh compost, as recommended by Emmerton in his book, published in 1819—is largely superfluous; but at the same time I would recommend that where a plant, on account of growth made, has a portion of stem exposed, it should have this stem covered by an application of fresh soil in order to encourage new root growth.

The Auricula is not over-fastidious as to the soil in which it will grow, provided it be thoroughly fresh and sweet. A suitable compost for the purpose of this top-dressing would be four parts loam of medium texture, one part leaf-mould, and one part thoroughly rotted hot-bed manure, with half a part of sharp sand added. Press this compost firmly round the collar of the plants up to the base of the leaves.

Seed-sowing.—Now is a good time for the beginner in Auricula-growing to put in some seed, but not the kind that is sold at a few pence per packet, for, from the Auricula-grower's point of view, this is worse than useless. Not only are the

plants raised from it of no value, but the time spent on it is wasted. The seed from which most pleasure and success is obtained is that which is home grown and cross-fertilised by hand; that is, supposing you have a collection of the best varieties to work with. This, of course, is beyond the reach of the beginner, so do the next best thing and get your seed from a grower of repute, even if you have to pay 2s. 6d. for a packet, and leave the cheap seed severely alone.

I would suggest that the beginner commence with seed of the alpine section, as being easier to grow and giving a larger percentage of good flowers than does the show section.

Use seed-pans or pots in which to sow the seeds, as, owing to its slow germination, the pots have to be kept eighteen months or so, and boxes in that time often decay and break.

I will not enlarge on the process of seed-sowing, as I take it for granted that this is already understood by anyone who undertakes Auricula-growing. Sow thinly and cover the seed with a light covering of soil about the thickness of a shilling; put a sheet of glass on the pot, stand in a cold frame away from the direct rays of the sun, and see that the soil is not allowed to become dry. The seedlings will be six or eight weeks before they begin to appear, and some will not germinate for twelve months. I will close by wishing all Auricula-growers a good season with their plants, and by hoping that many recruits may be gained to the societies.

G. J. S.

DAFFODILS IN NEW ZEALAND.

I HAVE read the article, "Daffodils in New Zealand," by Mr. A. E. Grindrod of Auckland, with much interest, and consider that we have much to thank him for in drawing attention to the way the cult has found enthusiastic adherents in this part of the world. There are one or two things in it to which exception may be taken. He says: "There are, I understand, no growers in our capital province (Wellington), though Mr. Thomas Mason (now deceased) raised some good things which have unfortunately gone astray."

I will take the first part of the sentence, where he says that he does not know of any growers in the Wellington Province. There are several who are actively engaged in the work. Mr. Joseph Weightman has been crossing and hybridising for some years now, and has some really fine things. He has succeeded in lengthening our Daffodil season considerably, as he has a flower which he has named Harbinger that is in full bloom in May, before many of the other varieties are showing through the ground. He also has some very fine tridymus which surpass any of the varieties I have seen that are in commerce. He has paid great attention to white trumpets, and has some really fine varieties. One he calls Mrs. J. Weightman is a grand flower of great substance. Another trumpet (unnamed) is a distinct khaki in shade. His collection of seedlings must comprise some twenty to thirty thousand bulbs, and there are plenty among them that will be welcomed when he can be persuaded to put them on the market.

There are others who are raising seedlings, notably Messrs. A. J. Hobbs and Buckingham of the Lower Hutt. These men are keeping careful notes of their crosses and the results, and have got at least two that are a due reward.

One is a large bold trumpet with plenty of substance in the cup and perianth, and the other is an incomparabilis with white perianth and a creamy coloured, much-expanded cup with a distinct band of deep apricot round it.

In reference to the late Mr. Thomas Mason, I should like to tell Mr. Grindrod that all his seedlings have not gone astray. Some of them are still being grown and looked after by his children. When Mr. Mason raised his seedlings he was doing a pioneer's work and had not got the splendid articles in THE GARDEN that we now have to encourage and guide us in the right direction. Consequently, many of those that he considered superior to those of his day are superseded now. I can easily remember the pride with which he showed some seedlings of Sir Watkin and his explanation that this variety rarely seeded in England. He thought a great deal more of selection than of seed-raising, and said that selection would play a very important part in the future. In respect to one variety, Sir Watkin, he was quite right, as his selection of this variety is superior to anything I have seen. He always considered that New Zealand was an ideal place for bulb culture. I have seen some of the bulbs raised in Auckland, and quite agree with Mr. Grindrod that they are good.

What is wanted in New Zealand is a series of shows beginning with Auckland, then Wellington, Christchurch and Invercargill in rotation, and a committee of "daffys"—I beg your pardon, daffodilists—to go from show to show and then sum up the best of the seedlings from notes taken en route. Owing to the length of the Dominion from north to south the seasons vary considerably, and while Auckland's gardens are ablaze with Daffodils, those in Wellington are only just opening, and so on down to Invercargill.

Feilding, New Zealand.

FRANK MASON.

[We thank our esteemed correspondent for his most interesting article and kind remarks about THE GARDEN. We shall be pleased to send a specimen copy free to anyone specially interested in Daffodils in New Zealand.—ED.]

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

VALUE OF BELAMCANDA SINENSIS (A. B.).—The plant is not of much value, and only cultivated by a few amateurs or specialists. As a market plant it is not in demand, and the best way to dispose of the plants would be to advertise them for sale at a cheap rate in THE GARDEN.

INJURY TO VIOLET LEAVES (Alfriston).—The material sent is insufficient to enable us to be sure of the cause of the trouble from which the Violets are suffering. Can you send us some roots? The roots of Violets are often attacked by the root eelworm (see answer to a correspondent in our issue for February 7) and sometimes by a fungus, and it is very desirable that we should have complete plants to examine.

THE GARDEN.

No. 2206.—VOL. LXXVIII.

FEBRUARY 28, 1914.

NOTES OF THE WEEK.

Solomon's Seal as a Pot Plant.—The graceful and pleasing habit of this old favourite plant is well known, although it is very seldom used as a pot plant. Pieces of root placed in pots now and grown on in a little warmth will soon give a good display of fresh green foliage—which is much brighter than when grown in the open—and drooping flowers. A few plants of this mixed among other flowers will greatly improve the appearance of the conservatory. The plant is readily accommodated and easily forced into bloom in an ordinary greenhouse.

Autumn-Fruiting Raspberries.—These should be cut close to the ground each season, as the fruit is produced on the current year's growth. It is good practice to lift and transplant part of the stock each season, as by this means the production of suckers is reduced and a larger quantity of fruit obtained. Although these are not so extensively grown as one might expect, they are worthy of a place in every garden, and should be planted with a view to extending the soft fruit season. Alexandria and November Abundance are two of the best. If not already done, Raspberry plots should be lightly pricked over and a surface-dressing of manure given.

Cypripedium fairrieianum Losing Vigour.—It is stated by more than one Orchid-grower that the plants of *C. fairrieianum* are beginning to lose their vigour, as did the first importation. The reason given by a contributor in the current issue of the *Orchid Review* is that the plant resents too moist and even airs and temperatures. Its habitat is no longer a secret, and it grows at a considerable elevation where the nights are cool and where the sky is clear. This species is said to enjoy the same conditions as *C. insigne*, except that it likes a warmer position in the summer. Those whose plants are seeming to dwindle and losing vigour are advised to give them a more airy and colder treatment in the winter, and a sunnier and more open-air treatment in the summer.

An Early Yellow Hyacinth.—Yellow is the last colour that the Hyacinth "took on." It is only in consonance with this fact that all those of this colour are, as a rule, late-flowering. A variety that will flower in the first half of February with ordinary greenhouse treatment is one to make a note of for another year. We recently saw a small batch of Buff Beauty, and were much attracted by both its colour and its spike. It may be described as a pale buff, with a long, well-filled, but not overcrowded truss of semi-

double, good-sized bells. The stem is wiry and strong, which is a decided advantage. Buff Beauty is quite distinct in colour to Orange Boven, a ruddy orange, to which we called our readers' attention this time last year.

Young Asparagus Sprengeri.—Although everyone knows the utility of the long sprays of this "Asparagus Fern," as it is so often popularly but erroneously called, there may be some who

After these have served their purpose, they may be thrown away and the same process repeated next spring, as the seed is both cheap and easily obtainable.

Erica carnea in the Rock Garden.—At this time of the year *Erica carnea* is greatly appreciated by virtue of its masses of pink flowers. It is a low-growing species, not exceeding 6 inches in height, and it never fails to produce a carpet of bloom in February and March. It is an excellent subject for planting in the foreground of the rock garden, where the flowering branches are allowed to grow more or less unchecked over the fringe of rockwork. Like most other Heaths, it spreads rapidly in a sandy peat soil, or it may readily be grown in a loamy soil if there is no lime present.

An Early Flowering Plum.—*Prunus Amygdalus persicoides* was in full flower on February 22, or just a month later than last year. As a rule, it is at its best about the first week in March in the neighbourhood of London, or about a fortnight before the ordinary Almond. Its almost white blossoms are quite as large as those of *P. Amygdalus*, and are borne with equal freedom; therefore it might well be planted with a more lavish hand than at present, for all trees and shrubs which hasten spring by blossoming early are deserving of every encouragement. There is some doubt as to the origin of this particular variety, and some people consider that it is a hybrid between the Almond and the Peach. To be well placed, it should have a background of dark-foliaged trees, otherwise the effect of the flowers is partly lost.

Rock Gardens at the Chelsea Show.—It is within the bounds of possibility that the Royal Horticultural Society's show to be held at Chelsea in May will be minus the rock and formal gardens that last year were so great a source of interest to visitors. Rightly or wrongly, the society has imposed very severe restrictions on outdoor exhibitors. The latter argue that exhibitors in the tents have shelters and any necessary

ERICA CARNEA, A BEAUTIFUL HARDY HEATH THAT IS FLOWERING NOW IN THE ROCK GARDEN.

have never tried it as a pot plant in a young state for room decoration. If seed is sown now in 2½-inch pots—one seed in each little pot—and the whole batch plunged in a seed pan or box filled with fibre, germination soon ensues. The little plants may be grown on where they are until they are almost root-bound, when they may be potted on into 3½-inch pots. If these are well looked after, they will next year make most useful little bushy plants for room decoration, and be a welcome change from true Ferns.

staging provided free by the society, which is put to no corresponding expense in connection with the outdoor exhibits. Granted that the society is bound by its agreement with the Chelsea Hospital authorities, we think that some leniency might be shown towards the outdoor exhibitors. The rock and formal gardens are, if the weather is fine, the greatest attraction of the show, and the Council might guarantee some, at least, of the expense of repairing any damage that may be caused to soil and turf.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Caterpillars on Cabbage.—These may easily be killed by syringing with a solution of nitrate of soda in water, 2 per cent. to 4 per cent. For caterpillars on Gooseberries the same means may be used, but the Gooseberry bushes will not stand more than 1 per cent. to 2 per cent.

Viola odorata Kaiser Wilhelm II.—This is identical with Princess de Galles (Princess of Wales). It is a splendid Violet where it finds suitable conditions, but this very rarely happens. Ascania or Baroness Rothschild, which is said to be the same, generally succeeds much better, and it is quite as good.—J. S. Rus, Denmark.

Ceanothus Gloire de Versailles.—In your issue for February 7, page 73, it is stated that this shrub will not stand cold. Here in a very windswept place I have a Ceanothus Gloire de Versailles growing in a bed that is situated in a draught between a wall and the house, so draughty that I have to tie all the branches to stakes for the winter. The plant stands north and north-west frosty winds, grows 2 feet a year, and is full of bloom each summer.—HENRY TOLSON, Poppleton, York.

A New Winter-Flowering Begonia.—By the courtesy of MM. Lemoine et fils, Nancy, I am in receipt of a description and photograph of a new winter-flowering Begonia which they think highly of and intend to put into commerce during the coming summer. As these raisers have given us so many fine varieties, including the universally popular Gloire de Lorraine, it is evident that their knowledge of these beautiful plants is considerable. The variety, which is named Nancy, was awarded a certificate of merit by the National Horticultural Society of France in January, 1913, and a work of art at the Paris Autumn Exhibition in October of the same year. It is the result of a cross between *B. socotrana* and *B. Baumannii*, a tuberous, sweet-scented species from Bolivia. This new variety will flower from October to March. The leaves are round and peltate, and the flowers, produced well above the foliage, measure from 2 inches to 3½ inches in diameter. They are of a bright carmine rose, and are slightly scented. Although the male parent is a tuberous species, the hybrid does not produce tuberous rootstocks, and there is no marked period of rest; in short, the variety Nancy may be given much the same treatment as Gloire de Lorraine.—H. P.

Hardiness of *Spiræa lindleyana*.—I was interested in your notes *re Spiræas* in the February 14 issue of THE GARDEN, page 82. You mention that *S. lindleyana* is not quite hardy except in Devon or Cornwall. It may interest your readers to know that here in Woodford we have a specimen

which has wintered three or four seasons outdoors, and is now again in bud. It grows very rapidly, without the least shelter or care, in a garden facing the open country.—F. O. LOUDEN, London House, Chigwell Road, South Woodford.

Rhododendron moupinense.—In reference to this *Rhododendron*, illustrated on page 96 of THE GARDEN for February 21, it was found by Mr. E. H. Wilson in Mupin in September, 1908, and the seed came to England in the spring of 1909, so that this seed has been in England just five years. He found it again in October, 1910, and sent seed to England in March, 1911, so that there should now be many plants of it in cultivation. Mr. Godman of South Lodge, Horsham, flowered it last year.—J. W. C.

BEGONIA NANCY, A NEW WINTER-FLOWERING VARIETY WITH BRIGHT CARMINE-ROSE, SLIGHTLY SCENTED, BLOSSOMS.

Sweet Pea Diseases.—One reads with interest Mr. F. J. Chittenden's remarks on page 79, February 14 issue. Personally, I cannot grasp just what is meant by "a check." One treats their plants with infinite care, yet streak comes along. Years back I always shook out my plants, and yet they recovered from such a check, often lasting a month when chilly winds followed planting. In more recent times I have planted from pots, but streak still remains with me, despite the fact that within the past eight years I have moved four times, on each occasion planting my Sweet Peas on ground that has never before seen such a crop. Successive years of streak attack have made me less and less inclined to spend extra labour on Sweet Peas, and last year, with just plain digging and moderate manuring, I got my plants to

last well into August, a gain of nearly a month. My own view is that dryness causes more disease than moisture, providing, of course, that the soil is not stagnantly wet. Sterilisation has not yet proved its worth. I have chemically treated my ground, without results, while one well-known grower even steam-sterilised many tons of soil, but streak was as bad as, or worse than, ever.—T. W., Kent.

Colour Effects with Annuals.—The criticism of your esteemed contributor, Mr. Turner, on page 79, February 14 issue, has been most welcome and instructive to me, as I happened to be responsible for the planting of the borders illustrated in the coloured plate in the January 3 issue of THE GARDEN. Upon taking charge of these gardens a few months previous to the planting

season, these borders were known as herbaceous borders, and were in a dilapidated condition. I came to the conclusion that the prospects of a display were remote. The plants were taken out, and as the borders had not had consideration in the seed order, I had to make the best of what I had, and I reluctantly introduced the white and blue which have drawn the criticism. Coming to colour effect, I agree with Mr. Brotherston's remarks (page 30, January 17 issue), and would reject blue where pink and carmine are associated, especially so in this case, where the background is a high hedge and dense trees. Personally, I am inclined to think Mr. Jenkins' remarks (page 8, January 3 issue) were based solely on a display of annuals, rejecting colour effects altogether; and I believe there are many employers who prefer a great show of colour to the much-preferred arrangement for colour effect. The diagram shown by Mr. Turner will doubtless prove of great assistance to many during the next few months, and no doubt Mr. Brotherston will lay before your readers an article on this interesting subject.—WILLIAM H. DUROSE, The Gardens, Westwood, Tilehurst. [We hope Mr. Brotherston will do so.—ED.]

Cyclamen Monstrosities.

Looking over the various groups of Cyclamen on the second Royal Horticultural Society's meeting in January, one could not help contrasting the clear-cut, neatly

thrown back, typically petalled varieties with the heavy and deformed-looking crested and fringed modern developments, which, I suppose, are only tolerated because we live in an age when novelty seems to have run mad. How unlike our old, smart, well-groomed favourites are the gorged, grovelling and grotesque gruesomenesses that we only know are intended to be flowers because they are placed at the ends of the peduncles! Quoting from an old poem on gardening:

"Flowers their Titles must to Merit owe

In Flora's Commonwealth, as they shall blow:

Must lose their Peerage, if they run away

From their true colours, and the false display."

How much more when it is form and not colour!—JOSEPH JACOB.

PEAT MOSS MANURE: IS IT INJURIOUS?

THE letters on this subject that we published last week have created a great deal of interest. Below we publish a further selection.

WE have found the peat moss litter manure very useful here, and used (before the days of the motor omnibus) a good deal of it at one time. It is very fiery stuff, and should stand a year in a heap before using. We have only used it as a top-dressing and mulching, or for digging in for rough crops. I should not dig it in for roses and such like, but we found it very good for working into ground before sowing poppies. The great thing is to let it ferment for a year. It is dangerous stuff in the fresh state.

Royal Gardens, Kew.

W. J. BEAN.

IN our opinion peat moss litter manure should on no account be dug into the soil, as in many instances we have known it to set up a fungus which has badly affected plants, and we consider it very much inferior to straw manure.

Wordsley, Stourbridge. E. WEBB AND SONS.

I AM interested in the question of peat moss litter manure. I went into the subject some time ago and compared notes with others, and the result was that I was driven to the conclusion that the peat moss manure was quite good, although in certain circumstances it was injurious. This, I thought, and still think, was caused by the litter absorbing an excessive quantity of urine and being applied too fresh. In light soils I consider the peat moss litter manure more beneficial than in heavy soils. A point which seems to have largely escaped attention has been the acidity of some peat, but this may be rendered innocuous by the drying process. A very large grower of early Potatoes here secures all the manure from the large horse-keepers in town and carts it away daily. He makes a large heap, which lies until required, and this contains a big proportion of peat moss manure, which is much used by horse-keepers here. He allows the same price as for the straw manure, and I am sure he would not do so if he were not convinced of its value. Personally, I would prefer straw manure if I could get it, but I could not hesitate to use the other.

S. ARNOTT.

Sunnymead, Maxwelltown, Dumfries.

I HAVE used peat moss litter a good deal, and it would be excellent were it not for a tendency sometimes to engender fungus, owing, I imagine, to the source of the peat. I would not, however, prefer it to well-decomposed farmyard manure, because here we have the manure both of cow, pig and horse; but if I were confined to ordinary stable manure as often cleared out of stables where carriage horses are kept, I think I should prefer the peat moss litter. The peat absorbs the urine, which renders it a very powerful manure, and if mixed with the soil, care should be taken to keep it well away from roots. Undoubtedly its chief value is as a top-dressing. If the soil is covered thinly with it at intervals, it is a fine stimulant, and the after-hoeing blends the peat with the soil, thus creating a nice humus, and it keeps

the surface soil in a nice workable state. Perhaps a blending of the two, peat litter and farmyard manure, would be an ideal manure.

W. EASLEA.

Danecroft Rosery, Eastwood, Essex.

I HAVE used peat moss litter manure quite successfully, and never noticed any bad results, though for choice I prefer straw manure.

EDWIN BECKETT.

Aldenham House Gardens, Elstree, Herts.

THE origin of the manure in the first place may exert a considerable influence on a crop. That from a stable where a few horses are kept may be much better than that from a stable where from fifty to a hundred horses are littered each night and where quantities of disinfectants are used, or where the litter is allowed to become saturated with urine. Then the nature of the land and the character of the crop have to be taken into consideration. When used as a surface-dressing, it is pretty generally admitted that it does little or no harm, but when dug into the ground in a fresh state it has certainly had a detrimental effect on certain crops.

An article on peat moss litter manure appeared in the *Kew Bulletin*, No. 8, 1911, pages 349-51. In this article reference is made to its deleterious effect upon certain plants after it had been inadvertently dug into beds, though it had been used as a top-dressing for a considerable time without ill effects. Samples of the soil and the manure were examined by Dr. Voelcker, and the following paragraphs, a portion of his report, are taken from the above-mentioned article: "I have come to the conclusion—from my examination—that the ill effects in the present case are due to the marked acidity of the manure, this acidity being due to organic acids in the manure and not to mineral ones. I find in the soil (in which the manure has been used) iron compounds present in the ferrous—or not fully oxidised—condition, and it would seem to me likely that these are the result of the liberal use of an organically acid body such as the peat moss, and that an unhealthy, imperfectly oxidised condition of the soil has been brought about.

"Very probably if the manure be kept longer and allowed to rot more thoroughly, it becomes more aerated and oxidised, and then would not show the ill effects noticed."

W. D.

MY own experience with peat moss litter manure, agriculturally, has been favourable. It can be ploughed into ordinary lightish soils and loams without any bad effect whatsoever. Horticulturally speaking, I am led to understand that it should be used primarily on light soils, since in heavier ground it is apt to produce insufficient aeration, and tends to cause sourness. In this way it would simply fall into line with the usually accepted rule to use long manure on heavy soils and short manure on light soils. Its absorbing power for ammonia is very much greater than that of Wheat straw, and consequently as a manure it should be fairly rich. It decomposes, however, rather slowly in the soil. The composition of peat moss itself shows it to contain 0.7 per cent. nitrogen, 0.1 per cent. phosphoric acid and 0.1 per cent. potash.

University College, Reading. S. J. M. AULD.

YOUR correspondent is correct when he states that peat moss litter has no manurial value in itself, but we cannot agree with him when he says that it would be dangerous to dig peat moss litter manure into the soil. The general opinion regarding this manure, as gathered from the various articles and replies to correspondents appearing in the agricultural and gardening papers, is that it is quite as useful as straw manure; but we would like to point out that it is necessary for it to be properly treated before it can be used. Moss litter itself contains a certain proportion of humic acid, and even after use in the stables there is still some of this left; consequently, it should not be put straight on to the land, unless mixed with lime to neutralise the acidity. Although some people do put it straight on to the land, it is far better to make a heap of it and let it stand for a few months before using, in the meantime saturating it with water or liquid manure, and turning it several times to expose it to the air and get rid of any trace of the acidity. Comparing peat moss with straw manure, the former proves to be twice as rich in nitrogen as the latter, and this is, of course, of considerable value. Dr. Watts gives the following analysis:

	Straw.	Peat Moss
Water	75.42	62.53
Organic matter ..	16.53	21.14
Phosphates ..	0.96	2.56
Alkaline salts ..	4.43	3.60
Insoluble matter ..	2.66	2.17

	100.00	100.00
Containing nitrogen ..	0.61	1.24
Equal to ammonia ..	0.74	1.50

Experiments have been conducted to ascertain the value of the two kinds of manure, and we may briefly mention the result of trials at the Cockle Park Demonstration Farm, Morpeth (see the *Journal of the Board of Agriculture*, September, 1906). The manure was applied to two plots on light soil for Swedes, with the result that 12 tons of moss litter manure gave 25.7-10 tons of Swedes an acre, while 10 tons of straw manure gave 23½ tons of Swedes an acre. The report further states that all through the season the Swedes manured with the moss litter looked best. One of your contemporaries had an article on the value of peat moss litter, in which reference was made to the unfavourable report from Kew on peat moss litter manure. The writer, Hjalmar von Feilitzen, Ph.D., Director of the Experimental Station of the Swedish Peat Society in Jököping, says that the results obtained at Kew do not agree with those of other countries, and he gives a brief account of his experience. He finds that the effect of peat moss litter manure on vegetables was always better than that obtained from other litters, and on garden plants and flowers very favourable. The manure was used both as a top-dressing and mixed with the soil. The writer concludes by saying that as regards the unfavourable results obtained at Kew, there is no evidence that it is due to the moss litter used, as no comparable experiments appear to have been made.

JUDGING EXHIBITION VIOLAS.

[In Reply to a Correspondent.]

THE question raised is one that constantly recurs as each successive exhibition period comes round. How to judge a show Viola is not so easy to answer as

A GOOD EXHIBITION BLOOM OF FANCY VIOLA MAVOUREEN.

many people may imagine. So far as I am aware, there is no published record of what are the properties of a show Viola. I have looked into old publications dealing with the show and fancy Pansies, and I find that to make the show Viola conform to rules laid down for blooms of the show and fancy Pansies, as regards their properties, would be to lessen the beauty and charm of the Viola. The show Pansies are so distinct from the Violas as we know them to-day; the latter are so free and graceful in their character, and they possess a beauty peculiarly their own. No hard-and-fast rule can be laid down as to what a good Viola should be, and this remark applies to the question of size, form, colour or marking.

Beauty in respect to form, whatever the type may be, colour and marking, each has to be considered by those appointed to judge exhibition blooms, and the better these points are exemplified in the flowers set up for adjudication, the more will they commend themselves to judges who are true florists. Points worthy of consideration are the following: Size.—There is a tendency to give too much attention to size, to the exclusion of many flowers of smaller varieties that possess points of quality far in excess of those seen in the unduly large flowers that are often very coarse. It is not difficult to determine what are well-grown flowers, and if these are a little above the average size, they always look well. In whatever way

the flowers may be set up, whether it be in sprays, as was the rule years ago, or in bowls filled with sand, the blooms should be of consistent size and form. Prizes have often been lost because an exhibitor has arranged in a spray, &c., one or two undersized blooms. In such cases the better blooms have set the standard of quality, and the smaller ones have exhibited how far they have fallen short of the standard.

Then as regards colour, this, too, should be consistently good. Care is very necessary when gathering the blooms that the self-coloured sorts should be as nearly alike in colour as possible, and that fancy and edged flowers should be even in their markings and margins. In the nineties, when twelve sprays of Violas were set up, it was customary, in the classes for six blooms in each spray, to give one point as a maximum for each bloom, so that it was possible to obtain seventy-two points for a series of perfect sprays. In very close competition additional points were awarded for variety, arrangement and general effect. This system of awarding points works out very well, for in ordinary competitions, by allowing one point to each perfect bloom as a maximum, this may be reduced by fractions or otherwise in proper ratio for blooms less perfect. The total number of points gained by each competitor can then be very easily determined.

Other considerations that are important in exhibition Violas are the following: Small, neat, bright eye; flowers that are well balanced, absence of ragged or notched edges, freedom from waviness and blemishes, such as punctures by insects and dirt splashes. Most important of all, the flowers should be absolutely fresh. Stale flowers and any that may be in the least disposed to curl at the edges should be discarded in favour of fresh blooms, even though they may be smaller. Preference should be given to blooms of stout, velvety substance, with the petals lying evenly and closely upon each other. Such blooms invariably last longer and maintain their fresh-

ness throughout the day of the show. The "Rules for Judging" issued by the Royal Horticultural Society defines the points in judging Violas as follows: (a) Good outline and stoutness of petal, one point; (b) smoothness of petal and edge, one point; (c) in selfs, well-defined colour, one point; (d) in belted and blotched flowers, harmony without confusion, two points; (e) erect, stout stems, blooms facing well to the front, one point. Each of these points has practically been dealt with in these notes, so the matter should now be perfectly clear. One judge who knows his business could judge the flowers quite satisfactorily; but, so that suggestions of incompetence or uncertainty shall not be made, it is much better to obtain the services of two men who know the Viola and its varieties, and in case of a disagreement it should be possible to call in an umpire.

Highgate, N.

D. B. CRANE.

WHY FORCED BULBS FAIL.

EELWORMS EATING THE ROOTS.

FOR a long time I was uncertain whether eelworms (by this term I do not mean the real creature, *Heterodera radicola*, but a white, worm-like grub with a black head, the larva of a gnat-like fly) really destroyed the living roots of bulbs, or that they were merely scavengers, eating up roots which had already decayed through the attacks of fungus or other causes. Many an argument have I had with a good Daffodil friend on this subject, he holding to the scavenger view, while I upheld the other theory. Then, some bulbs having been submitted to an expert, my opinions were for a time upset by him saying that the trouble was caused by a fungus and not by the eelworm.

However, only just lately I have quite satisfied myself by discovering the creatures actually at work in the living roots of a Daffodil. Not one

VIOLAS ARRANGED WITH YOUNG HAWTHORN SHOOTS FOR EXHIBITION, IN A PAN OF WET SILVER SAND.

only, but three or four were seen in the field of a small Coddington lens at one time, while the effects of their ravages were plainly observable in the tunnelled-out roots and frayed edges of the same. I have not the slightest doubt but what this pest is the principal cause of the failure of bulbs in pots, accounts of which constantly appear in your "Correspondence" columns and those of your contemporaries. I feel almost certain that these worms are not present in the dry bulbs, but are in the potting soil. My reason for this opinion is that one never finds bulbs attacked when grown in fibre, but only when grown in fibrous loam.

Sterilisation of the soil seems to be the only remedy, and when soil has been thus treated it should be done some months before it is used; in the meantime it should be turned several times, so that it may get well aerated. I have tried several soil sterilisers, both liquid and solid, but the eelworm seems to *thrive* on them all. It is curious to notice how "chancy" the growing of bulbs is in infested soil. For instance, at the present time I have a box of Daffodil Golden Spur as good as one could wish for, while another box of the same bulbs in the same soil has quite half the bulbs destroyed. Anyone who has constantly suffered from the attacks of eelworms can tell at a glance when the bulbs are affected, for, instead of the leaves growing freely away as they should, they make a feeble effort and then come to a standstill, and if the grower will take hold of the growth and give a firm pull, he will find the bulb come up without much resistance, the roots having been eaten away.

One may examine a great many bulbs before finding the worms at work, one reason being that, having done their fell work, they may have moved to fresh fields and pastures new, and another reason being that the wretches are rather lively in their movements, and unless the roots are examined immediately after the bulb is removed from the soil, they will have wriggled away under cover of soil or the old skin of the bulb.

Of course, eelworms are not the only cause of failure in bulb forcing, for some people can manage to spoil the best of bulbs even without their aid. Only quite lately my firm had some bulbs of Daffodil Golden Spur sent by post which only had one poor flower to six bulbs. On examining these it was found that every bulb had an embryo bud within, but the bulbs had evidently been submitted to too much heat and they had "gone blind," a disaster which will often happen when bulbs are given too high a temperature. Those who force large numbers of bulbs for the cut-flower trade find that only a few degrees will make the difference between success and failure. This is especially the case with Darwin Tulips. Mr. Leak of Messrs. Bath, Limited, who made such a grand exhibit of these Tulips in fibre last year, told me that it had taken him several years to find out the exact temperature to suit them.

It is unfortunate that when the average amateur has a failure with his bulbs, he immediately lays the blame on the bulbs themselves rather than on his methods of cultivation or the soil used in potting. The man of experience, on the other hand, looks to every other thing (soil, temperature, watering, &c.) before he thinks of condemning the bulbs.

Some years ago, when judging pots of Tulips at the Midland Daffodil Show for prizes offered by the late Mr. Robert Sydenham, I had a lesson I have never forgotten. There were some six entries for the prizes, and there one could see very good, indifferent, and very poor plants, all grown from the *same* bulbs supplied by *one* firm! I wonder if the growers learned the same lesson

IRIS 'CANTAB, A BEAUTIFUL CHANCE SEEDLING OF STRONG CONSTITUTION.

that I did, or whether the producers of the poor pots went away blaming our old friend "Uncle Robert" for sending them poor bulbs! I would say, in conclusion, that turfy loam contains far more insect-life, often including eelworm, than does ordinary garden soil; so it might be well for those who have had bad results from bulbs grown in turf to try their ordinary garden soil, to which might be added sand, leaf-mould, Cocoanut fibre, or anything in that line which would tend to keep it open and sweet. In fact, it would be better to rely upon fibre only than to use soil known to be infested with eelworm, unless it had been previously sterilised.

Lowdham, Notts.

J. DUNCAN PEARSON

A CHANCE SEEDLING IRIS.

IRIS CANTAB.

ON this page appears an illustration, almost life-size, of the new bulbous Iris which gained an award of merit at a recent meeting of the Royal Horticultural Society. This charming variety, which has pale blue standards and pale violet falls, with golden orange crests, originated as a chance seedling in Mr. E. A. Bowles' garden at Waltham Cross. It is probably derived from *I. Krelagei* or Max Leichtlin's *I. cyanea*, both of which were growing near to the place of origin. Although not unusual for Irises of the *reticulata* group to be weak in constitution, the new seedling, which, by the by, was shown by Mr. Herbert Chapman of Rye, grows very freely and multiplies rapidly, and for this reason it is likely to prove quite an acquisition for the open border. The flowers, which are borne about six inches from the ground, are fragrant, while they are far exceeded in height by the vigorous, deep green foliage.

THE CULTIVATION OF COB NUTS AND FILBERTS.

NUTS and wine! This phrase brings to mind a Georgian interior, mahogany tables reflecting the light from many candles, while the port, with due solemnity, makes its journey round the board. But, as times change, the Nut becomes divorced from vinous liquors and figures as the main course of a vegetarian meal, a scene of frugality contrasting strangely with the older picture. But whether we take our Nuts in the old or the new style, Cobs and Filberts have a special appeal to English tastes. When the demands of these Nuts as to soil are considered, it is rather remarkable that they are so little planted. They will grow in practically any soil, but in moist ground they are apt to make wood rather too freely, and it is upon dry and rocky soils that they flourish best. In Kent the limestone rock called "ragstone" offers an admirable

subsoil, and with the smallest of loam deposits on the surface the Cob grows to a remarkable age. Trees of 200 years can be seen planted 12 feet to 15 feet apart, and as they are tolerant of shade, Apples, Plums and other fruits are grown as standards between them. There must be many gardens where a dry, sloping bank or a neglected corner exists which could be made fruitful and pleasing to the eye by the planting of Nuts. The varieties now are many. A learned monograph in German lies before me which describes some eighty-seven kinds. The average gardener, however, will be content with rather less than this, and a good selection will be as follows.

GUNNERAS GROWING ON THE MARGIN OF A POOL IN AN ESSEX GARDEN.

The earliest to ripen is the Prolific Filbert. This old sort was found in a Norwich garden about 1840, and is remarkable by reason of its curiously frizzled husks. The Nuts are small but sweet and are produced in bunches, often as many as twelve being found in one cluster. The Kent Cob or Lambert Filbert, so called after its raiser, Mr. Lambert of Goudhurst, Kent, is not really a true Cob, but is the best all round Nut now grown.

The distinction between Cobs and Filberts is a very old one, and consists in the fact that in the Cob the Nut is not fully covered by the husk, while in the Filbert it is entirely so. The Kent "Cob" is therefore properly a Filbert. The old Kentish Filbert, which is considered by many to be the best flavoured of all Nuts, has now largely dropped out of cultivation on account of the greater fertility of more modern kinds. Some of the best Nuts are the seedlings raised by Mr. Webb of Calcot about thirty years ago, and one of them, Duke of Edinburgh, can be highly recommended for its excellent flavour. The Cosford is a most prolific variety, with a shell so thin that it may be cracked in the fingers (fairly strong fingers are required!), and Merveille de Bolwyller is probably the largest of all, a vigorous grower and of first-class flavour. The Purple-leaved Filbert is perhaps more often seen in the shrubbery than in the fruit garden, and its fruits are sometimes overlooked, as the husk and shell are of the same

the garden, giving with so little expenditure of time so satisfactory a return. E. A. BUNYARD.

ROCK AND WATER-SIDE GARDEN AT COPPED HALL.

COPPED HALL, Epping, was at one time a retreat of pleasure and privacy for the Abbots of Waltham. At the present time it is owned by E. J. Wythes, Esq., who cherishes not only the historical associations of Copped Hall and its surroundings, but also the immense trees and the rare beauty of the spacious flower garden and lawns, which are pleasantly designed and admirably maintained. Remnants of the ancient garden of the monks are to be seen in the grand old Yew avenue which was figured in our issue of February 14, while the old-time interest of the garden is enhanced by the presence of venerable trees of the Cedar of Lebanon and a remarkably fine specimen of the Deciduous Cypress, *Taxodium distichum*. The Yew avenue leads to a shady and sequestered dell, now converted into a rock garden of rare beauty and delight. Although the position is too shady for many flowers of the High Alps, which rejoice in all the light and air they may receive, yet there are many shade-loving plants which furnish this dell and make bright patches of colour at varying seasons,

purplish red colour as the leaves. As to the culture of these Nuts, there is hardly a more long-suffering plant in the fruit garden; but the trees will, nevertheless, repay occasional manuring, and wool waste, rabbit fur, or feathers are largely used for this purpose in commercial plantations in Kent.

In the Maidstone district a very restricted pruning is adopted, and a basin-shaped tree is preferred. The fruits on these trees are very large, naturally more so than those gathered from trees where less thinning is adopted, as in the north of Kent. The crops obtained from these trees are very variable, but are estimated at 7cwt. to 8cwt. per acre over a series of years, while in years when there is a shortage, such as the present, the price of the Nuts is often 1s. a pound or even more. Altogether there is no more useful plant to fill up odd corners of

while the neighbouring tree trunks are clothed with *Ampelopsis* and *Clematis* in variety. Though it was in the dull time of the year that our visit was made, the fine effects created by perennial Candytuft, *Cerastiums*, *Campanulas*, *Primulas*, the American Wood Lily (*Trillium*), dwarf perennial Asters, London Pride and *Aubrietias* may easily be conceived. A little stream flows through the rock garden, and is crossed by stepping-stones partly hidden by the River Mimulus, *Primulas* of the japonica type, *Saxifraga cordifolia* and Ferns in variety, of which the Hart's-tongue (*Scolopendrium vulgare*) and the Oak Fern (*Polypodium Dryopteris*), together with *Aspidiums* and the Royal Fern (*Osmunda regalis*), are used with charming effect; while growing by the stream-side are such hardy aquatics as *Butomus*, *Alisma*, *Caltha palustris* and *Typha angustifolia*. A beautiful collection of suitable shrubs, including *Cotoneasters* or *Rocksprays*, Japanese *Acers* in great variety, *Berberis stenophylla*, *B. Darwinii*, *Azaleas*, *Hypericums*, *Kerria japonica* and *Bamboos*, is planted with good effect in the background of the rock garden. Flowering shrubs form one of the most delightful features of this garden, and many of Wilson's introductions from China were noted, while rarely, if ever, is *Romneya Coulteri*, the Californian Tree Poppy, seen grown to greater perfection than against a wall in these gardens. In another part of the grounds is seen a large pool of water, which is being converted into a place of unusual splendour. *Gunnera manicata* looks magnificent planted on the margin of the pool, while later on the bank will be gay with the blooms of Japanese *Anemones* (pink and white), Siberian Irises, *Rodgersias*, golden-striped Rush, and *Kniphofias* or Torch Lilies. *Bamboos* and Weeping Willows are also planted to great advantage.

COLOURED PLATE. PLATE 1488.

THE COLUMBINES.

AQUILEGIAS have long inhabited our gardens, and in a Herbal which bears the date of 1564 Dr. Turner mentions *A. vulgaris*. This is the botanical name of the common Columbine, and single and double forms of various colours are found in abundance in gardens all over the country. Several very charming species were introduced into England in the first half of last century, and these beautiful *Ranunculads* are undoubtedly the forerunners of the exquisite strains of long-spurred hybrids found in commerce to-day. *Aquilegias* are somewhat widely distributed over the globe, and species have been introduced from the dry, rocky districts of North-West Himalaya, from Siberia, Europe, Canada, and from Guatemala.

Many of the species introduced into England have ceased to find a place in catalogues, and their place has doubtless been taken by the long-spurred hybrids. One of the best of the species was *A. leptoceras*, the Slender-horned Columbine, and under this name it was figured in the *Botanical Register*, 64. It is described in the Journal of the Horticultural Society as having flowers of a pale bright violet, with the tips of the sepals greenish, the short petals a clear bright straw colour. It is a native of Siberia beyond Lake Baical. *A. jucunda*, another native of Siberia, at one time known as the Joyous Columbine,

is rarely met with in gardens. It differs somewhat from *A. glandulosa*, having an altogether dwarfer habit and flowers of a much brighter blue, and in its very glaucous, round foliage. It is a much easier cultivated species than *A. glandulosa*, and a very pretty coloured plate of it appeared in the *Floricultural Cabinet* for May, 1857. In the same journal a coloured figure is also given of *A. kanacriensis*, a native of Cashmere, introduced to the Royal Botanic Gardens at Kew by Dr. Thomson. The flowers, about half the size of those of *A. jucunda*, are nearly similar in colour, and it is not met with, nor even listed, nowadays. It was also figured in the *Botanical Magazine*, 4,693. The *Floricultural Cabinet* for August, 1853, in a description of new or showy plants in bloom during that month at the Royal Gardens, Kew, mentions *A. sibirica* and *A. fragrans*. Both are said to be showy, the former having large, deep blue coloured flowers, and the latter having very large flowers with the outside blue and the interior white. They are seldom met with now. Many other species were in cultivation about that time, and one of the most notable was *A. alpina*. This is one of the gems among the *Aquilegias*, and the true form is exceedingly scarce now. It is offered in lists, but the true *A. alpina* is hard to obtain. It is a native of the European Alps, bearing immense, spreading blossoms of a charming shade of blue.

Coming to the species that are very probably the parents of the long-spurred hybrids, one of the loveliest is *A. glandulosa*. This beautiful native of Siberia has exquisite flowers of clear blue, with white below. It is a difficult sort to grow well.

During recent years a hybrid variety named *A. Helenæ* has been introduced, and it is said to resemble *A. glandulosa*. The writer has tried it, and discarded it as worthless. Undoubtedly the best of the hybrids from *A. glandulosa* that have received a name is *A. Stuartii*, raised by the late Dr. Stuart of Chirnside, the well-known *Viola* raiser, and distributed by Messrs. Cocker of Aberdeen. This hybrid, like its parent, is difficult to cultivate well; but we now have many unnamed hybrids in the long-spurred section that are quite as charming, and have the virtue of being easily grown. *A. chrysantha*, a tall, graceful plant with clear yellow, long-spurred flowers, has left its stamp almost indelibly upon the long-spurred hybrids of to-day, and is certainly one of the species from which they have originated. It is a native of New Mexico. *A. Skinneri*, at one time named *A. mexicana*, is another species to which we owe our modern varieties. This well-known *Columbine* has crimson red flowers tipped with orange, and the green mouth of the blossom is a conspicuous feature. *A. californica*, a pretty native of North America, is certainly another parent of the long-spurred hybrids. The spurs and petals of the flowers are a vivid orange red, and the mouths of the tubes deep yellow. Doubtless *A. Skinneri*, *A. californica*, *A. cærulea*, *A. chrysantha*, and in all probability either *A. glandulosa* or *A. Stuartii* are the species from which the long-spurred hybrids have been derived in conjunction with the many garden forms of *A. vulgaris*.

Quite a number of the leading seed firms have given a lot of attention in recent years to the development of the long-spurred *Aquilegias*, and the wonderful exhibits of them seen in the early summer at the Royal Horticultural Society's meetings are always a centre of interest. Efforts

have been made to get the more beautiful forms to breed true to colour from seed, but this has never been done quite successfully. As already indicated, the new race of long-spurred varieties is easily grown. It is advisable to sow seed as early as possible, in order to get strong plants for putting out in September. Some growers believe in sowing the seed as soon as it is ripe, just for the purpose of getting the plants as forward as possible. They succeed in almost any good garden soil, but to obtain large, fine flowers the beds ought to be deeply cultivated and well manured. Quite one of the finest plantations of *Aquilegias* we ever saw was at Messrs. Dobbie and Co.'s seed farm in Essex. A very large bed was planted out for seed ten years ago, and last summer it was flourishing amazingly; in fact, most of the flowers depicted in our coloured plate were obtained from that bed, and we are indebted to Messrs. Dobbie and Co. for sending the collection of flowers to our artist.

HARDY CHINESE PRIMULAS

(Continued from page 93.)

P. Cockburniana (Hemsl.).—This member of the *Candelabra* section was introduced in 1906 from Tatsienlu, Central Szechwan, by Messrs. James Veitch and Sons, and was collected by Mr. Wilson. Its brilliant orange scarlet flowers at once attracted the notice of the public. Unfortunately, it has not proved so satisfactory in cultivation as was desired, and many apparently have to cultivate it as a biennial. It is a free seeder, and its short life in gardens is therefore not of so much consequence. In some places it is quite perennial, but not always under the same conditions. It is naturally a lover of moisture, yet sometimes is perennial in dry, well-drained soil and even in clay. It has Primrose-like leaves and whorls of stalked flowers on scapes about a foot or more high.

P. Cockburniana Hybrids.—Crossed with *P. pulverulenta*, *P. Cockburniana* has produced some beautiful hybrids. *P. × Unique* is a handsome plant with coppery brown flowers. This, recrossed, has given *P. × Excelsior*, a deeper-coloured but less hardy plant than *Unique*.

P. × Lissadell Hybrid, which is the reverse cross to *Unique*, is a finer plant than *Unique*, and is hardier and more deeply coloured. On a damp soil I find these hardy and satisfactory. Cultivation: Good rich loamy soil in half sun.

P. cortusoides lichiangensis (G. Forrest).—This is now generally known as *P. lichiangensis* (G. Forrest). It is a good garden plant, easy to grow, even in the border, and quite a satisfactory subject. It resembles the valuable *P. Veitchii*, but is distinguished from that species by the foliage, which is not white beneath, being less hairy, and by the larger, more drooping flowers, which have also a larger eye. The anthers are yellow in *P. Veitchii*, but purple in *P. lichiangensis*. It was collected by Mr. Forrest in the Tali region, Yunnan, and introduced in 1908 by Messrs. Bees, Limited. Cultivation: Any good soil; easily grown in half shade.

P. deflexa (Duthie).—The plants of this section (*Muscaroides*) are generally of difficult cultivation in a wet climate, owing to the hairs on the leaves; but *P. deflexa* appears to be the easiest to grow. It has rather erect-growing leaves, covered with downy hairs, and close spikes of narrow, lilac purple or bluish flowers, which, like the others of the section, are curved in the calyx and corolla so as to assume a drooping form. It is exceedingly fragrant. *P. deflexa*, which comes from

STEPPING STONES IN THE ROCK GARDEN AT COPPED HALL.

Western China, was raised from seeds sent by Mr. Wilson. It flowered in 1906. Cultivation: Good garden soil with ample drainage; shady situation.

P. denticulata (Smith).—This, or an allied form, is described as from Mengtze in South-East Yunnan. As it is more general in the Himalayas, it will be referred to in my notes on the Himalayan Primulas. *P. pseudo-denticulata* (Pax) is earlier than the type from India.

P. Forrestii (Balf. fil.).—Introduced from the Tali region of Yunnan in 1908 by Messrs. Bees from seeds sent by their collector, Mr. Forrest. This distinct Primula has been found difficult to cultivate. It has massive stems, large masses of evergreen leaves, and yellow, sweet-scented flowers. It does not do well with me in the open, but in some places thrives on dry rock or in a retaining wall. It belongs to the section *Suffruticosa*, of which there are few representatives in cultivation.

P. Gagnepainii (Petitue).—This is synonymous with *P. heucherifolia* (Franch.) and resembles *cortusa Matthioli* in its general appearance. It is very hardy and easily grown. The drooping lilac purple flowers are carried on stems several inches high. This Primula was introduced under the name of *P. Gagnepainii* by Miss Willmott, who received seeds from Mr. Wilson. Section *Geranoides*. Cultivation: Will grow in any soil and in any situation.

P. Giraldiana (Pax) was introduced by Messrs. Bees in 1908 and sent out under the name of *P. muscaroides*. It belongs to the same section as *P. deflexa*, to which it has a strong resemblance; but on a minute comparison marked differences emerge. While *P. deflexa* is sweetly scented, *P. Giraldiana* is scentless. In the former the foliage is downy and the stems covered with white hairs; in the latter the leaves have fewer, though larger, hairs, and the stems are hairless. The very small bracts of *P. Giraldiana*, as well as its flowers, are purple. It was collected in Yunnan by Mr. Forrest. Cultivation: No doubt in some places this plant may prove perennial in the open, but with me it does not. I grow it in pots in a cold house in soil composed of two parts pulverised loam, one part leaf-soil, one part silver sand; in half shade.

JOHN MACWATT.
(To be continued.)

A RARE SAXIFRAGA (S. MEDIA).

THERE are certain members of the genus *Saxifraga* that are particularly difficult to cultivate. *Saxifraga florulenta* and *S. Grisebachii* are two species which readily occur to mind. In *S. media* we have another that is likely to give a good deal of trouble in order to cultivate it successfully. When not in flower, this species closely resembles *S. Grisebachii*, possessing a similar compact rosette of leaves. In flower, however, it is quite

distinct, for, instead of producing a spike, it sends up a raceme with spreading branches 2 inches long, as depicted in the illustration. It is imperative that this plant should not suffer from damp, and for that reason it is best grown like *S. Grisebachii*, either in pots or planted out on a small cone of stones.

ROSE-GROWING IN TOWN GARDENS.

CLIMBERS FOR WALLS AND FENCES.

THE Roses best suited for growing against walls include most of the Noisettes, Hybrid Tea and Tea

with whom it succeeds will be more than amply repaid for their care and trouble. A light, rich soil suits it best, and when well established it should be kept going with liberal supplies of manure. The blooms are of a delightful shade of glowing rose pink, and are among the earliest to open and the last to go. François Crousse also appears to prefer rather light soil, and needs a sunny wall to bring out the best of its colouring, which is a bright crimson. Large-flowered climbers of this shade are none too numerous, and are often asked for. Tea Rambler (coppery pink) is pretty and useful, and almost the only multiflora that is at home on a wall. With a westerly aspect Mme. Alfred Carrière,

William Allen Richardson (Noisette) and Reine Olga de Wurtemberg will do well. The latter is a semi-double Rose, crimson in colour, with fine foliage. William Allen Richardson, orange yellow in the bud, fading almost to white in the expanded blooms, is sufficiently well known to need no description. Walls facing east will suit Mme. Alfred Carrière, Climbing Mrs. W. J. Grant, Gloire de Dijon (Tea), Alister Stella Gray (Noisette), Climbing Caroline Testout (Hybrid Tea) and Conrad F. Meyer (rugosa). The last named is a fine, useful Rose of a silvery pink shade, especially desirable because it usually produces the first large, well-shaped bloom out of doors; but the plant is rather prone to mildew when placed against a wall. Alister Stella Gray, buff, with orange centre, is particularly good in the autumn. Very few Roses will do well on a wall facing north, and in town gardens, where other advantages are denied them, it seems rather like cruelty to plant them there. Félicité Perpétue, to which I referred in a previous article as a Rose for a bad spot, is a notable exception, and Bennett's Seedling may also be made to grow in such a position.

Points to Remember.—At the foot of a wall or fence the soil is much drier than in the open border, and consequently climbers so placed will need careful mulching and hoeing, especially when first planted. The difficulty in getting a plant to start satisfactorily may generally be traced to dryness at the root during the first season. In planting, all the roots should be

spread out in fan shape, and should all point away from the wall.

Pruning.—All climbers for walls should be cut down the first season, so that only the strongest rods are left longer than a foot, and none more than 3 feet above the ground. Afterwards it becomes a matter of thinning rather than pruning, but unripe and dead wood must always be cut away. When growths are overcrowded, thinning is best done in the autumn, the oldest shoots being selected for removal. Hybrid Tea and Tea Roses may be pruned back slightly, but Reine d'Or and other Noisettes should be left almost untouched.

P. L. GODDARD.

SAXIFRAGA MEDIA, A LITTLE-KNOWN SPECIES FROM THE PYRENEES.

Roses of climbing habit. For walls facing south, the Noisettes Reine d'Or and Mme. Alfred Carrière, the Hybrid Teas Climbing Mrs. W. J. Grant and François Crousse, and Tea Rambler (*Rosa multiflora scandens*) are among the best sorts for towns. Noisettes require to become well established before they will bloom satisfactorily, and little can be expected of them until the third year after planting. Reine d'Or is somewhat tender, and should be grown only in the most sheltered spots. Mme. Alfred Carrière, the best white climber, grows well, is sweetly scented, beautiful for decoration and quite hardy. Climbing Mrs. W. J. Grant is rather subject to mildew, but growers

GARDENING FOR BEGINNERS.

ROSES FOR SMALL BEDS.

THE wild Bramble and the Dog Rose in the hedgerows look quite charming when growing in masses, really in an overcrowded state. The garden Rose crowded in small beds would not be as attractive, because it would present a very untidy appearance, the flowers would not be quite true to character, and the wood would not mature properly, so that the cultivator would meet with difficulties and much disappointment in future years. We must be content and wise enough to put in just as many Roses as the small bed will contain; then the plants will thrive.

There is often a certain amount of shade in a suburban garden. Well, many varieties of strong-growing Hybrid Perpetuals will do nicely in such positions, especially the dark red and deep pink ones, as the blooms do not fade so quickly as when the plants are grown in an open position fully exposed to the sun's rays. The strong-growing Hybrid Teas may also be planted in partial shade. That grand old favourite Gloire de Dijon does remarkably well there; the tints in the petals are much deeper and richer.

Ground may still be prepared and Roses planted. The soil must be deeply dug, the lower portion well broken up at the time, and the top left in a rough state. It is not necessary to put in any manure. The latter can be applied in the form of a mulch after the Roses are planted. Standards and dwarfs may be grown in the same bed—one standard in the centre of a small bed, and three in a larger one. Such beds are full of

HOW TO PRUNE DWARF AND STANDARD ROSES.

interest to the cultivator when there is no overcrowding. Fig. 1 shows how the cultivator must prune a strong-growing dwarf; and Fig. 2 a young standard.

It is too early to do the work yet, because, if the shoots are cut now, the buds that are left would quickly burst into growth. The young shoots formed would be very susceptible to injury

from cold winds and night frosts that are always experienced during March and the early part of April. If pruning is delayed for at least another three weeks, the lower buds will remain dormant, and in that condition will not be harmed by cold weather.

HARDY BORDER FLOWERS.

UNTIDY borders should not be tolerated in any garden. When one plant is allowed to grow into another, when old flower and leaf stems are left to decay on the plants, and when foreign matter is allowed to remain choking the young shoots of clumps of plants, the result is very unsatisfactory. The border is not attractive, and it actually makes the whole garden look untidy.

The new border must not be made by simply turning over the surface soil a few inches deep, and then putting in a few kinds of plants in a haphazard way. No; this will not do at all. The cultivator must trench the soil and do everything in a deliberate manner with the firm intention of having a really beautiful border, as it will go such a long way towards ensuring a beautiful garden. Then it will be advisable to plan the border for the plants, which should be mostly herbaceous. Some hardy annuals will be useful for filling up vacant places later on. The tallest-growing of the herbaceous plants must have positions near the back of the border, those of medium height in the centre, and the dwarf ones at the front. Before planting, make a rough plan of the border on paper, marking the positions so as to have harmony of colour and a regular succession of blossom from early in the summer till late in the autumn.

In the case of small borders, single specimens of many kinds of plants may be used; but where the border is broad and proportionate in length, clumps containing three, five, or seven plants would have the best effect. A good background forms a suitable setting for such border plants. Where there is no neat shrubbery, a row or clumps of Sweet Peas would do nicely. Hedges, neatly kept, will do. Wooden fences should be clothed with suitable climbing plants. On a low fence, quick-growing climbers, planted 6 feet apart, would do well and soon cover it.

In most mixed borders groups of spring-flowering bulbs, such as Daffodils, Tulips and Crocuses, are planted near the front, and these add considerably to the charm of the borders during the early months of the year. Unfortunately, when their flowers have departed, there is a more or less obvious gap, and this is where annual flowers are particularly useful. If seeds of such hardy kinds as Mignonette, Sweet Alyssum, Virginian Stock, Godetia, Clarkia, pot Marigold, Swan River Daisy, pink Mallow and Candytuft are sown between the bulbs at the end of March or early in April, the seedlings will be well advanced by the time the foliage of the bulbs is dead, and in the late summer and autumn will give a glorious display of flowers. If half-hardy kinds, such as Asters, Stocks, Nemesis and Zinnias are preferred, these can be raised in a cool frame or greenhouse and planted out between the bulbs about the third week in May. One of the chief values of annuals is their suitability for filling

temporary gaps during the summer and autumn months, and beginners would do well to utilise them more for this purpose.

CHARMING CLIMBERS.

IN nearly every garden climbing plants can be used to very great advantage. A few arches are soon erected; the more rustic-looking the better. Rough posts, too, will be found useful; and in the largest gardens, or in any affording the necessary space, pergolas would look very attractive. Avoid the erection of structures that are too light to withstand strong winds. The bare structure may, at first, stand all right; but when it is clothed with branches and leaves a greater strain is imposed, and it may be quickly destroyed, also the plants on it. Therefore be sure that the wood used is of sufficient strength.

A pergola must be erected over a straight path, arches too may go there; but the latter look well at the junction of paths and at almost any other point. Beside garden paths, dotted here and there, posts covered with climbers have a charming appearance. Below is shown a quite plain arch spanning the garden walk. It is well to fix the upright posts a few inches away from the edges of the paths to allow room for the branches of the climbers.

Of course, we cannot exclude the lovely climbing Roses. Then there are the fragrant Honey-suckles, the noble Wistarias, suitable for the long

ARCH SPANNING GARDEN PATH.

pergolas, also the Vines, which possess such richly coloured leaves. Clematises are charming. Ceanothuses clothe posts beautifully, and, if novelties are desired, put in a few plants of Wilson Junior Blackberry and Japanese Wineberries. Both kinds fruit freely and form a contrast in the colour of the berries, and both will thrive in gardens near towns.

G. G.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Fruit-Houses.

Early Permanent Vines.—If all has gone well with December-started Vines, the bunches should now be ready for thinning, and this should be done with great care. Carefully avoid touching the bunches with the hand, and do not thin too hard at first. Stop the shoots at the second or third leaf beyond the bunch, and gradually work them down to the wires a little at a time. Damp the floor and vacant parts of the bed twice daily, but avoid steam. The temperature may be 70° at night, rising to 85° by day with sun-heat.

Strawberries.—The early batch of plants will now have set their fruits, and should be placed near the glass in a warm forcing-house. Syringe the foliage twice daily, and give frequent waterings with weak liquid manure. A shelf at the back of a Melon or Cucumber house will suit them well. Continue to introduce plants to gentle heat as required.

The Plant-Houses.

Gloriosa superba.—The roots, having been dormant for some time, should now be potted up and placed in comfortable quarters. Loam and peat in equal parts, with a good quantity of rough silver sand, will suit them. Cover the roots about two inches, and if the soil is in good condition very little water will be necessary until growth shows through the surface of the soil, but the atmosphere should be kept moist.

Roses.—Plants in pots which were started early will now be growing freely and showing their flowers. At this stage they may be given light dressings of guano, which is one of the most reliable manures for this purpose. Overhead syringing should be discontinued, or mildew may prove troublesome. Ventilate carefully at the top of the house, and fumigate if green or black fly should make its appearance. Permanent Rose plants in cool houses will now require liberal supplies of liquid manure at the roots. Avoid cold draughts.

The Flower Garden.

Violas.—If these plants have been wintered in cold pits, the lights may be removed whenever the weather is favourable, so that the plants may be grown as stocky and short-jointed as possible. Stir the soil between the plants, and remove all small weeds.

Calceolarias.—The tops may now be pinched, and the young plants should either be potted up or transplanted in a cold pit in order to prevent them becoming drawn.

Herbaceous Phloxes.—To grow these to perfection it is necessary to trench the soil to a depth of 2 feet, and give a good dressing of decayed manure. The position should be somewhat sheltered from the sun during the warmest part of the day, or the colour of many of the best varieties will be impaired. In lifting and preparing the roots for planting, pull them to pieces with the hand, and plant pieces capable of producing three or four spikes each; by this means better flowers will be produced than if larger clumps are used. Allow 2 feet between the plants, and if hot, dry weather sets in, mulch the bed with decayed manure and give plenty of water at the roots.

Climbers on Walls should be pruned and regulated without delay. No hard-and-fast rule can be laid down as to the manner in which the different climbing plants should be pruned and trained. The position in which they are growing has a great deal to do with this; but in all cases overcrowding must be avoided.

Roses of the Rambler type should be carefully thinned out, removing as much of the old wood as can be spared and tying in the strong, young growths of last season's production. These Roses are not adapted for walls; but for pergolas or pillars where the air can pass freely among them they are well suited.

Hardy Fruit.

Mulberries, Medlars and Nuts.—The branches of these should now be carefully thinned so that light and air may pass freely among them. Remove all suckers from the base of Nut trees; but the

pruning of these may be delayed until the catkins are formed.

Pruning Young Trees.—The pruning of young trees is an important matter, and should be performed with great care, as the future of a tree largely depends on the way this work is performed during the early stages of its growth. The branches of a perfect tree should be furnished with fruiting spurs from top to base, and should be sufficiently thin for the sun to reach the centre. To attain this end, trees which were planted a year ago should be carefully thinned, leaving only sufficient branches coming directly from the stem, and these should now be shortened back according to their strength, and to a bud inclining outwards.

The Kitchen Garden.

Lettuce.—Young plants raised from seed in January should now be ready for planting in cold frames. The soil for this purpose must be light and rich, and within 18 inches of the glass. Allow a space of 6 inches between the plants each way, and when sufficiently advanced half the crop may be cut for immediate use, leaving every second plant to develop. Autumn-sown Lettuce should now be planted on a warm south border. Slugs will be their greatest enemy, but may be kept in check by frequent dustings of lime in the early morning.

Peas.—The early sown Peas will now require protection from rough wind. A few Spruce boughs should be placed along the rows for a few weeks. Let the stakes be placed in position as soon as possible. The early sowings in pots should be freely ventilated in a cold pit. Keep the plants near the glass, and do all that is possible to keep them stocky.

Potatoes.—These may now be planted on a warm south border, where protection from frost can be applied if necessary. The sets of second-early and maincrop varieties should be laid out thinly in a cool shed in order to promote the growth of sturdy shoots. A change of seed is advisable, especially if obtained from Ireland or Scotland.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

The Hot-Bed.—For obvious reasons the raising of seed and the production of a few early vegetables must have the protection of a hot-bed. If this has not been done, no time should be lost in getting together the necessary quantity of manure. This should be turned several times to prevent it becoming heated, and if it becomes too dry, a little water may be sprinkled over it from time to time. During the final turning add a quantity of dry leaves, which, I think, help to maintain a steadier heat. For growing vegetables, about a foot of soil will be ample.

Brassicas.—Most members of the Brassica family may now be sown out of doors. But it will not be wise to sow all the seed at once, especially in the case of Cauliflower, Cabbage and Brussels Sprouts. At the very least two sowings should be made. At the outset it will be wise to place a double net over the seed about two feet from the ground. This will not only act as a protection against birds, but I find it also acts as a protection for the young plants towards the end of the month.

Leeks.—The main crop of Leeks may now be sown out of doors. Many make this sowing in cold frames, but I do not think this is at all necessary. My experience is that they do equally well on a warm border. It is, however, essential that the seed should be sown thinly; otherwise one never gets sturdy plants for transplanting.

Carrots.—A small sowing of Early Horn Carrots may now be made on a south border. It will not be wise, however, to put in more than a few rows, because if these are not used in a young state they will most certainly run to seed.

Celery.—Those who did not make a sowing last month may now put in a little seed of one of the dwarf varieties. In the majority of cases this sowing will be quite early enough. As previously advised, see that the young plants do not receive a check, either through lack of moisture at the roots or extreme fluctuations in the temperature.

Cucumbers.—For those who grow Cucumbers in cold frames, seeds may be sown any time during the coming week. They should be sown in small pots. In cold districts it is good policy to pot them on, at least into 6-inch pots. By the time they are established in these pots they may be safely transferred to the frames. They will, of course, need a little protection on cold nights, and in the earlier stages of growth little or no air should be admitted.

The Flower Garden.

Larkspur.—This lovely annual is becoming more popular each season, and little wonder, as, apart from its attractiveness as a bedding plant, it is especially effective for decorative purposes indoors. It has, however, a nasty habit of going off mysteriously, even up to the time of flowering. To get over this, many gardeners treat it as a hardy annual, and sow it where it is to remain. Personally, I have always treated it as half-hardy, and, with the exception of a few odd plants going off, have been able to make a wonderfully effective display with it. I usually give the ground a good dressing of lime before planting. Sow the seeds now and bring them on gently, as coddling in any shape would only be courting failure. When large enough, prick out the seedlings into frames and plant out about the beginning of May. I find they do best if planted in a border by themselves, or at least in large patches in a mixed border.

Mignonette.—This is such a common plant and its requirements so well known that one need say very little about it. Yet one hears numerous complaints about its fickleness, and many times I have been asked if I could account for its failure to germinate. Some years ago I saw a long border sown entirely with Mignonette and only a few plants appeared, whereas the following season almost every seed grew, which would suggest that there was something wrong with the preparation of the seed-bed. Before sowing see that the ground is made very firm (this I consider essential), and thin out the plants when quite small. If this is not attended to, the plants will last only a short time in bloom.

Pillar Roses.—No time should be lost in completing the work of tying up pillar Roses and other climbing plants, as after this date much damage may be done to the young shoots, which will now be very prominent.

Plants Under Glass.

Hydrangeas.—These indispensable greenhouse plants can be had in bloom over a very long period of the year. Cuttings may be rooted now, and again in the autumn. Those struck now will produce immense heads by September, while those rooted in the autumn will flower the following spring and summer. Older plants may now be brought from their winter quarters and pruned. They will be found to make fine specimens for the conservatory.

Salvia splendens.—Old plants of this useful winter-flowering Salvia should now be looked over, partly cut back, and placed in a warm vinery to produce cuttings. Like all other Salvias, this variety is a rapid grower, and cuttings put in at the end of this month will make handsome plants towards the end of September.

The Hardy Fruit Garden.

Strawberries.—Where planting was not done in the autumn, the present will be a suitable time to get this done, although it will not be wise to delay this work much longer. Those planted now should have the flowers pinched off as they appear, which will assist the plant to build up the crown for fruiting the following season.

Planting and Pruning.—The planting and pruning of all hardy fruit, which, through various causes, could not be done earlier, should now be completed.

Fruits Under Glass.

Melons.—This is a crop that must be regulated according to requirements. At this season Melons will take fourteen to fifteen weeks from the sowing of the seed until the fruit is ripe. Midsummer crops will take twelve to thirteen weeks. It will always be wise to allow a little longer in each case, as one never gets good flavour unless the house is well ventilated as the fruits approach the ripening stage.

THE USE OF LIME IN THE GARDEN.

LIME is present to a greater or less extent in all soils excepting peat and the poorer sands. Its presence is essential to the maintenance of fertility, as it has many important duties to perform, both in the soil and in the body of the plant itself. Yet, strictly speaking, it is not a food—that is, it is not actually required in the intimate chemical structure of the living parts of the plant. Nevertheless, it contributes more than anything else to the proper nutrition and general health of our crops. So far as its beneficial actions in the soil are concerned, in the first place its presence improves the physical or mechanical condition of both light and heavy soils. It binds sands and improves the texture of stiff clays. The great fault of a clay is its extreme closeness of texture; the individual grains are so minute and they are packed so closely together that little space is left for air or for the downward movement of water. The presence of lime causes these grains to coagulate into little groups or masses, and so opens the soil and thus materially improves its texture. Certain obvious results follow: The movement of water through the soil is rendered easier and more rapid, the soil dries quicker in the spring, and this favours earlier warmth and, as a result, earlier crops. The consolidation following the application of lime to light soils increases their water-holding power, an important factor during a dry growing season.

In the second place, lime exercises important chemical activities in the soil. It is a well-known fact that lime readily neutralises acids. Lime-water added to sour milk will correct its acidity, and chalk added to vinegar will act in the same way and produce the same kind of result. Similarly, quicklime or ground limestone mixed with a sour soil will neutralise its acidity and render it sweet and wholesome to the roots. The application of lime in some form or other is the only practical method open to a gardener to correct sourness in the soil. An acid soil is very distasteful to the roots of the majority of cultivated crops, and, furthermore, it interferes with the activities of useful soil bacteria. On the other hand, such root diseases as club-root are encouraged by acidity of the soil. The particular form of fungus that induces this disease can only thrive and multiply in a soil which is acid in its reaction; therefore a generous application of lime to such a soil is the only real practical method of combating this troublesome form of disease. It is because of this peculiarity that cruciferous crops on calcareous soils are never affected with club-root. In this connection it ought to be remembered that the use of certain artificial manures—superphosphate of lime and sulphate of ammonia especially—tends to destroy the carbonate of lime present in the soil, and thus by their continued use bring about an undesirable acidity unless corrected by the occasional application of fresh supplies of lime. It is not only in connection with the question of acidity that the chemical activities of lime favour the gardener's work. Lime has a direct influence upon the liberation of plant food that otherwise might remain locked up in an insoluble state. This is especially true with respect to phosphorus and potash, two of the three most valuable constituents of the food of garden crops. By the action of

lime the insoluble salts of these essential elements are gradually brought into solution in soil water.

It is, however, in its third relationship that lime exercises such a potent influence upon the fertility of a soil, namely, in its relation to the biological activities of the soil. Apart from the direct application of such "artificial" nitrogenous manure as nitrate of soda, all the nitrogenous food of crops is prepared for the roots through the agency of living bacteria. The chief source of supply is the organic matter or humus present in all garden soils. Dead roots, fallen leaves, ordinary stable manure, &c., all contribute to the soil's store of humus. But before any such material can be utilised as food by crops, it must be broken down or fermented by vast hordes of putrefactive or decay bacteria. The most important end product of decay is ammonia, because it contains the valuable nitrogen in its chemical molecule. But relatively few plants appear to be able to make use of an ammonium salt; a further transformation, therefore, must take place before it is available. It is at this point that lime becomes so essential a constituent of the soil. All well-drained, cultivated soils support a vast population of bacteria concerned in nitrifying ammonia. In point of fact, there are two definite and distinct races, one engaged in oxidising ammonia into nitrous acid, and the other continuing the work by oxidising the nitrous into nitric acid. The function of the lime is to neutralise the acid immediately it is formed, so that nitrate of lime accumulates as a direct result. This nitrate of lime is the chief source of the nitrogenous food of all garden plants. The progress of nitrification thus depends upon a sufficiency of lime being present in the soil. It follows, therefore, that, if the supply runs out, the nitrification stops, as the nitrifying bacteria are checked in their growth if the acid products of their activity are not immediately neutralised. Nitrification is at its best when the soil is fairly moist and warm, when it is well aerated, and when it contains a sufficiency of lime. The absence of any one of these factors will check nitrification.

The particular point I am anxious to drive home in this connection is this: That the presence of lime in the soil encourages the activities of all those races of soil bacteria that are concerned in the preparation of nitrogenous food for cultivated crops. I am convinced that there are a large number of gardens the soils of which are heavily charged with rich stores of humus, but which, owing to the lack of lime, are unable to unload their treasures. In such cases it is lime, not additional manure, that is urgently required. The soil is fat, sluggish and inert, whereas it ought to be alive, buoyant and active, having its food reserves rapidly transformed into nitrates for the nutrition of our crops. Lime, therefore, is the most active agent in the transport service of the plant. It carries valuable food up to the absorbing root-hairs; but, comparatively speaking, it rarely enters the plant itself. Supposing it presents itself in the form of a nitrate. In the act of absorption the nitrate is decomposed, the nitric acid is absorbed by the living root, while the lime is left behind. The now freed lime instantly makes a fresh combination with the carbonic acid given off by the breathing root, and thus again in the form of a carbonate it is ready to repeat its part in the work of nitrogen transportation. A certain percentage of lime, however, enters the plant, as it is needful in the performance of certain duties in the living tissues

of the plant. One such duty only need here be mentioned. During the process of growth certain acids are formed, which, if allowed to accumulate, would interfere with the health of the tissues. These acids are neutralised by lime and thrown out of solution in the sap in the form of crystals. Some plants are able to excrete their excess of lime. This is well demonstrated in the case of "crustaceous" Saxifrages, where the white incrustations that appear along the margins of the leaves represent compounds of lime carried out in exuditions of sap which, on evaporation, leave the solid lime salts behind.

As is well known, certain plants dislike lime, and their spontaneous appearance in a soil indicate the absence of lime in that soil. The common Dock Sorrel (*Rumex acetosella*), the Foxglove and *Erica cinerea* are examples of such plants, and gardeners are familiar with many others which under cultivation must be kept free from lime; but these cases do not in any way affect the general question. It is worth noting, however, that Principal Wright found by direct experiment in the West of Scotland that the application of lime to the soil had a distinctly bad effect upon the yield of Potatoes, and he recommends that Potatoes should not be planted in ground recently treated with lime.

D. HOUSTON.

Royal College of Science for Ireland.

ACETYLENE GAS GENERATOR REFUSE

FOR GARDEN CROPS.

DURING the last few weeks a great many readers have written for information respecting the use of acetylene gas refuse, and we therefore reprint the following, which appeared in *THE GARDEN* for March, 1909. "The question of the usefulness or otherwise in gardens of the refuse from the acetylene generator plants is very frequently raised. 'May this refuse be placed upon the land without injury to crops and with beneficial effect upon the soil?' is mostly asked. Calcium carbide is made by causing lime and carbon to combine together in an electric furnace, so that a compound having the chemical formula CaC_2 is formed. When water is brought into contact with this substance, certain chemical reactions immediately take place, with the result that acetylene gas is generated and a white substance remains mixed and partly dissolved in water. This is shown by the following chemical equation:

The white substance is slaked lime, and if it were not for the presence of some impurities, derived mostly from the form of carbon used in the manufacture of the carbide (that have, of course, been ignored in the equation), this slaked lime would not differ in the least from that obtained when fresh burnt lime is slaked with water.

"On account of the presence of some impurities in the carbide, however, the refuse is likely to contain certain compounds of sulphur and lime (sulphides), and occasionally some phosphide of lime, a compound of phosphorus and lime. Both of these compounds are injurious to plant-life, but the latter is not likely to be present in sufficient quantities to do any appreciable damage, and the former soon alter in composition in the soil and become innocuous. Thus the refuse may be used with advantage upon soils,

though it should first be exposed to the action of the air for a time before it is allowed to come in contact with roots. It may be spread on the soil in the autumn at the rate of about half a bushel to the square rod, as evenly as possible, and allowed to lie for a time before it is forked in. Used in this way it will have the same beneficial effects upon the soil as a dressing of slaked lime applied in the same way, counteracting sourness of the soil and mitigating the evils arising therefrom, and, in the case of clay soils, causing the minute particles of clay to coagulate and therefore making the pores in the soil larger and the soil itself easier to work, more open to the air and, as a result, more easily warmed by the sun in the spring. SCIENTIST."

IS THE DAFFODIL A FLORIST'S FLOWER?

IN his interesting discussion as to whether the Daffodil ought or ought not to be considered a "florist's flower" (THE GARDEN of January 31 and February 7), Mr. Jacob asks me a number of questions which, with your permission, I shall do my best to answer. Why was Mr. Jacob asked to judge the Daffodils at Barnstaple, and not Tom, Dick or Harry? This question is so easy as to be almost difficult. Why, because Mr. Jacob is Mr. Jacob, and not any random individual you may chance to pick up. Tom, Dick and Harry may be estimable persons in their way, and may even know a Daffodil from a Dandelion when they see it. I have nothing against Tom, Dick or Harry, except that none of the three happens to be Mr. Jacob, and that, when I have Daffodils to show, I prefer to submit them to someone whose knowledge of the flower is above suspicion; someone who has seen all that there is to see in the way of Daffodils, who has grown them and shown them (peradventure even measured them with a foot rule) and who has written about them with enthusiasm and distinction. Mr. Jacob happens to fill the bill.

Again: Should I prefer the head-gardener of the nearest big place to judge my Daffodils to, say, Mr. P. D. Williams? I hesitate to say that there is any judge in the wide world I should prefer to Mr. P. D. Williams; but as concerns the head-gardener in question, I should have to know more about him before I suggested that he was not "the man for Galway." I suppose, as a rule, head-gardeners have so many claims on their attention as hardly to allow of their becoming specialists in a particular flower. My acquaintance with head-gardeners is not extensive, but I know (or knew) of one at least to whose judgment I should not hesitate to submit my Daffodils.

The broadside of queries with which Mr. Jacob opens the second instalment of his article I can best answer by conceding the necessity for shows, which I do very readily; also the necessity for recognising "points," if by "points" Mr. Jacob means certain desirable qualities which we all recognise when we see them. But such points must be manifestly desirable, and not arbitrarily selected by a junta of florists merely because the qualities in question are difficult to secure. If judges bar certain colours, combinations of colours, rays, stripes, pencillings, blotches and what not, it must be because these are thought to be intrinsically ugly and undesirable, and not because they run counter to certain florist conventions.

Why, for instance, may the edge of a Carnation petal not be fringed? A fringed petal is a charming feature in a Begonia, Pink or Poppy. But the florist rules it out as improper in the Carnation. Again, why, to have a chance with the judge, must an Auricula have a thrum eye? There is nothing disgraceful or inherently ugly in a pin eye. It is a thing of Nature's designing for a special purpose of her own; and, in my experience of the Primula tribe, she perpetrates a pin eye quite as often as she achieves a thrum. I myself do not admire pin eyes; but that is because I have been badly brought up (am, in fact, a florist in disguise), and proves nothing. I daresay there are people who prefer the pin eye to the thrum, and, if so, how must these inoffensive amateurs wince at the indignity put upon their taste by the florist! Coming back, then, to the Daffodil, there are accidental features of the flower which please one and displease another. We may prefer a red eye, or an eye of another colour; a perianth segment like the ace of spades or one of another shape; a flower that looks up or a flower that looks down, or a flower that looks straight ahead. These are unessential points on which the best judges may agree to differ. On the other hand, there are certain things we all desire in the flower—size, substance, purity and delicacy (or depth) of colour, massiveness, symmetry, proportion, and so on, to all of which qualities a competent judge will surely give their full value, without any Glenly at his elbow.

Finally, may I be permitted to suggest to Mr. Jacob the reason why he is so equally divided between "Yes" and "No"? It is, I think, because he has not determined for himself what exactly he means by the word "florist." Sometimes he has in his mind the florist of the old school, now almost, if not quite, extinct, who tolerated only one or two types of a flower (the Tulip, for instance), and judged them by rigorous and sometimes by arbitrary standards. Sometimes the "florist" of Mr. Jacob's vocabulary means exhibitor, sometimes hybridiser, and sometimes little more than the skilful grower. I myself am a florist because I prefer maximus to Santa Maria; Mr. Farrer is a florist because he approves of hybrid Saxifrages; John Heal was a florist because he created a new race of Begonias. No doubt, in various senses such as these we are all florists. But how many of us are florists in the sense in which Glenly was a florist? However, when all is said, I am glad to believe that any differences between Mr. Jacob and myself are of the purely academic kind. As regards the essential points of Daffodils and Daffodil culture, I do not remember any on which I do not agree with your distinguished contributor. Let him not even think that I undervalue the Spanish loveliness of Santa Maria. But, then, she is so "uncertain, coy, and hard to please"!

SOMERSET.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

PLANTS FOR A SMALL POOL (H. S. H.).—There is no reason why you should not do as you suggest with your Lily pond by introducing soil among the stones. Here and there the soil should be brought within from 3 inches to 6 inches of the surface of the water to accommodate such plants as succeed best where the water is shallow. In the deeper water you may plant the Flowering Rush (*Butomus umbellatus*), double-flowered Arrowhead (*Sagittaria variabilis* flore pleno), variegated Myrtle Grass (*Acorus Calamus* variegatus), narrow-leaved Reed Mace (*Typha angustifolia*) and *Richardia africana*. Where the water is shallower, *Iris sibirica*, *I. laevigata*, *I. pseud-acorus*, *Caltha palustris* flore pleno, *C. polypetala*, *Calla palustris* and the Bog Bean (*Menyanthes trifoliata*) may be grown. The plants should be procured and planted as soon as possible.

WATER LILIES IN GARDEN PONDS (Colonel W.).—There is no reason why Water Lilies should not thrive excellently in your ponds. The best way to establish them would be to drain the water away and make mounds of good loamy soil, kept in position by whole turves and bricks, on which to plant the Water Lilies. As a rule, the top of such mounds should be from 1½ feet to 2 feet below the surface of the water; a few inches either way, however, makes little difference. Planting should take place at once; in fact, it is already rather late. The following are really good kinds: *Nymphaea gladstoneana*, white; *N. William Falconer*, red; *N. tuberosa flavescens*, yellow; *N. Marliacea carnea*, pink; *N. robinsoniana*, red; and *N. alba candidissima*, white. We suggest that this number will be sufficient for your requirements, as they soon form large plants.

THE GREENHOUSE.

LILY OF THE VALLEY FLOWERING WITHOUT LEAVES (J. P.).—The German-grown crowns of the Lily of the Valley that have been forced hard to get them in flower early will throw up their blossoms without showing any foliage. Owing to this, retarded crowns are usually employed for very early flowering, as they produce leaves as well as flowers. As the season advances, the German crowns will push up the leaves and flowers together.

FERNS FOR CONSERVATORY (E. S. L.).—Any of the following Ferns will suit your requirements: *Adiantum aethiopicum*, *A. Capillus-veneris*, *A. decorum*, *Asplenium bulbiferum*, *A. Colensoi*, *Blechnum occidentale*, *Cyrtomium falcatum*, *Davallia canariense*, *Lastrea aristata* variegata, *Nephrodium molle corymbiferum*, *Onychium japonicum*, *Osmunda palustris*, *Polypodium aureum*, *Pteris cretica*, *P. c. albolineata*, *P. c. cristata*, *P. c. major*, *P. c. nobilis*, *P. internata*, *P. longifolia*, *P. l. Mariesii*, *P. nivalis*, *P. scaberula*, *P. serrulata*, *P. s. cristata*, *P. s. gracilis*, *P. Summersii*, *P. Wimsettii* and *Woodwardia orientalis*.

DIPLACUS GLUTINOSUS (Atherstone).—Generally speaking, *Diplacus glutinosus* should be given much the same treatment as a *Fuchsia*, except that it should not be kept so dry during the winter. It is best propagated by cuttings of the young growing shoots, taken in the spring when they are about a couple of inches in length, inserted into pots of sandy soil, and placed in a close propagating-case till rooted, which will not take long. A compost made up of loam, leaf-mould and sand will suit it well. As soon as your cuttings are rooted, they should be potted into small pots, giving them a warm situation in the greenhouse to encourage growth, and shifting them on into larger pots when required. They will flower well in pots from 6 inches to 8 inches in diameter.

TREES AND SHRUBS.

BUDDLEIA COLVILLEI (E. S. L.).—This is of rapid growth, but as a rule it flowers only when it has attained a fair size. As your plant is in such good condition, we should not advise you to prune it at all. It is altogether more tree-like in stature than *B. veitchiana*.

COTONEASTER FOR NAME AND TREATMENT (Japonica).—The specimen sent for identification is *Cotoneaster microphylla*, a native of the Himalaya. It may be propagated by seeds sown at once in sandy soil in a warm greenhouse or frame; or cuttings of young shoots, 3 inches to 4 inches long, may be taken in July and inserted in pots of sandy soil, or in a bed of sandy soil, in a close frame. A good compost for cuttings is made up of two parts loam, one part leaf-mould or peat, and one part silver sand. Make the compost moderately firm before inserting the cuttings.

HONEYSUCKLES NOT FLOWERING WELL (F. B. L.).—Your Honeysuckles are not likely to bloom any more satisfactorily if you cut them down and allow them to make new growth. As you say they are growing among Roses and Hops, we suggest that they are rather heavily shaded at times, and perhaps too crowded to allow of their obtaining a proper circulation of air among the branches. Roots of other plants may rob the Honeysuckles of food, and thus make them too weak to flower. As a rule, Honeysuckles succeed most satisfactorily when grown alone. We, however, advise you to leave them as they are for another year, and you may obtain flowers during the summer. It is difficult to advise correctly regarding the cause of non-flowering without seeing the plants and the exact conditions under which they are growing.

THE GARDEN.

No. 2207.—VOL. LXXVIII.

MARCH 7, 1914.

NOTES OF THE WEEK.

Early Daffodils at Wisley.—In the Royal Horticultural Society's Garden at Wisley may be seen at the present time colonies of the delightful *Narcissus cyclamineus* naturalised under trees and flowering to perfection. The dainty, rich yellow flowers, about six inches from the ground, spring up from a carpet of soft green moss in shady woods. This is one of the earliest Daffodils to flower, and is of great value for naturalising in woods or near the water's edge.

Planting Raspberries.—The present is a suitable time to make a new plantation of Raspberries. If possible, select a plot where they may be planted in rows running north and south. As a rule, no trouble should be found in getting sufficient suckers from existing plantations.

Our Spring Number.—Next week we shall publish a special enlarged spring number, containing many practical and interesting articles on seed sowing, the late planting of Roses, perennials, ornamental shrubs, and other plants. The illustrations will be of a unique character, and as there is sure to be a large demand for this issue, we advise readers to order copies well in advance.

An Attractive Winter-flowering Tree.—*Cornus Mas*, the Cornelian or Jew's Cherry, is one of the earliest of our flowering trees, with its clusters of yellow blooms, which are borne so freely on the trees at this season. As the trees get old they commence to bear fruits freely, and these are red and as handsome as a Cherry. In many places on the Continent selected varieties are grown for the sake of their fruits, which are excellent for preserving, and they might be grown more extensively in this country for that purpose. It is very effective, particularly where it is as a background of large conifers.

Crocus Sieberi.—This is one of the best known of the "species" Crocuses, and we imagine that everyone who goes in for these charming flowers includes this variety in their collection. It has been particularly good in many gardens this last February on account of the open weather. It is of such a short, sturdy habit that wind that could play havoc with the larger and taller *C. imperati* and *C. tommasinianus* has but little effect on *C. Sieberi*. We pen this note because

we believe that there are many gardens where this gem is as yet a stranger. This should not be so. It should be as widely distributed as the ubiquitous and universally loved fine old-fashioned Dutch Yellow, which Forbes Watson calls in his famous book, "Flowers and Gardens," "Most gladsome of the early flowers," and then goes on to say why it should never be taken up and divided. *C. Sieberi* is a small flower compared with this, but it has such a daintily shaped, goblet-like bloom of such a pleasing shade of deep but brightly hued mauve that it, too, will have admirers whose name will be legion when it is distributed in our gardens as its merits warrant.

NARCISSUS CYCLAMINEUS NOW FLOWERING IN THE WILD GARDEN AT WISLEY.

Pruning Street Trees.—This is the season when municipal and urban authorities usually turn their attention to the so-called pruning of the street trees in their respective districts, and, judging by past experience, a word of warning is very necessary. All too often we see these trees so hacked and mutilated as to render them cripples for life, and mere caricatures of what Nature intended them to be. In large cities, where the street trees are usually under the control of a practical and experienced man, the evil is not often perpetrated; it is in smaller towns, where the work is supervised by the town clerk or sanitary inspector, that the mutilation is rife.

That some curtailment of the branches is at times necessary we are fully aware, but this can be done without making the trees look like giant clothes props or mops. Perhaps some day urban or borough councils will realise that street trees are an asset to their respective towns, and secure and act upon practical advice concerning them.

Sparrows and Yellow Crocuses.—Just now we have a good many Dutch Crocuses of various colours in the garden, and, with the exception of the yellow varieties, these are unmolested by the sparrows. The yellow ones, however, have been plucked and torn to tatters with a vengeance that is almost fiendish. It would be interesting

to know whether this is the general experience of readers, and whether any reason for this selection of yellow varieties for destruction has been put forward. Hitherto the sparrows have left the yellow Crocuses alone in our garden, although, of course, we are well aware that others have not been so favoured.

Standard Plants for Summer Bedding.—Old plants of Fuchsia, Heliotrope, Plumbago, Abutilon and strong-growing Pelargoniums may be shaken out of the soil in which they have been wintered, and potted into a compost of turfy loam and leaf-soil with a good sprinkling of rough sand. Place the plants in a temperature of 55°, where they may be syringed twice daily. Seedling plants intended for this purpose may be kept growing in a temperature of 60° until the required height is reached, when the tops should be pinched out and the resulting shoots stopped again after a few leaves have been made.

Hyacinth Garibaldi.—Garibaldi is a Hyacinth of outstanding merit for early flowering in pots. It can easily be had in good condition in mid-January, or, with a little extra heat beyond a usual greenhouse temperature, earlier still. When the bells are expanding, it is something of the colour of General Pelissier, but as the bloom ages it develops a singularly effective shade of rich, glossy crimson and the petals become gracefully recurved, showing a pleasing contrast between their interior and exterior, as by this time the outsides have become flushed with quite an orange tone, which is very pronounced in a good light.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Lady Hermione as a Border Carnation.

Please allow me to take exception to the statement by Mr. Brotherston on page 96, issue February 21, about the above Carnation, "that it can be kept in health *only* by pot culture." We grow this variety out in the border, among others, right through the season, and at the time of writing no variety could be looking more healthy and vigorous, the leaves having that desirable gloss and Malmaison-like curl so noticeable with this particular sort. This testimony will be strengthened by adding that Highgate is considered a cold district, and the subsoil is solid clay not more than 2 feet below the plants. The foregoing applies to one year and two year old plants, the layers being wintered in pots or boxes in a cold frame. Last year Lady Hermione was in every way most satisfactory with us.—C. TURNER, 3, Kenwood Road, Highgate, N.

I doubt if anybody could tell one from the other. At the last Royal Horticultural Society's show it was noticeable that a great number of Gloria and major were exhibited with only one or two flowers on each. Naturally, they were larger than on plants more profusely flowered. I offer no opinion whether the plants with only one or two flowers had been disbudded, but we all know what the result is when Roses bear only a few blooms for exhibition purposes.—ALPINIST.

Peat Moss Litter Manure.—The remarks in THE GARDEN of February 21 and February 28 respecting the value of peat moss litter as manure are interesting, and I am pleased to see the opinion of distinguished men upon it, also that many have had better results from its use than I have had. Last season, owing to the scarcity of farmyard manure here, we used peat moss litter which had come from the stables and had been given time to decompose. Our soil is a light, porous loam, resting upon a well-drained gravel subsoil. Alternate years I endeavour to work our soil 2 feet deep, using straw manure between the

Vegetable Marrows and Broad Beans we lost in the same way as the Peas. For satisfaction I forwarded samples of the affected plants and the peat manure, as used, for investigation to a scientific expert at a research laboratory, who endorsed the view I had—that the mischief was due to the presence of mite, which he freely found in the manure and plants sent.—H. FRENCH, *Forthampton Court Gardens, Tewkesbury.*

— Moss litter has been used with farmyard manure to prevent the wastage of ammonia; it seems to fix this element and conserves moisture well. Therefore it is beneficial, when used with farmyard manure, on light soils, but on soils of a heavy nature it would tend to increase the acidity.—JAMES CARTER AND CO., *Raynes Park.*

Lenten Roses as Cut Flowers.—I have read the article on Lenten Roses in your issue for February 21, page 95. As regards the cut flowers, we have lately tried the plan of hammering the stalks gently, so as to split them without breaking them too much, and find that the flowers remain quite fresh for some time. This is also the case with Maidenhair Fern, the fronds remaining quite fresh, sometimes for as long as ten days.—M. M. CAMPBELL.

A Fine Plant of Garrya elliptica.

Few evergreen shrubs are more attractive than *Garrya elliptica*. This handsome Californian plant, with its long, tessellated catkins, of a peculiar yellowish green, measuring from 8 inches to 10 inches, forms a very striking appearance against the dark green, coriaceous foliage, which somewhat resembles the Evergreen Oak. Although generally grown against a wall, it is more ornamental in the open, where a plant 11 feet high and 32 feet through, as shown in the illustration, growing on a lawn, is a very attractive feature during this time of the year. The plant is dioecious, the male being the more handsome; the female plant is seldom seen in gardens. It succeeds best in rich, loamy soil, and is readily raised from seed, by cuttings, or layers. If any pruning is required to keep it in shape, it should be done directly after flowering.

The plant illustrated is growing in the Botanic Garden, Cambridge.—F. G. PRESTON.

Miniature Hyacinths.—Many of my friends in Holland are, I know, readers of THE GARDEN. I would like to ask them, more especially those who make a speciality of Hyacinth culture, if they could not unearth a few more kinds like Orange Boven, which I saw was mentioned not long since in "Notes of the Week"? This is one of the varieties that look well in its miniature form. It is then a true counterpart of the Roman Hyacinth, which I consider the ideal type for true "miniatures." Thin, tall, stiff stems, with medium-sized, well-shaped bells, lightly and somewhat sparsely arranged upon the spike, constitutes my idea of perfection. Very many of those now sold as miniatures depart too far from this standard to be really pleasing. It looks as if growers have put young three year old bulbs on the market without ever considering the appropriateness of the variety to be grown in this way. A yellow variety that I once had under the name of Fleur d'Or was just such another as Orange Boven.—JOSEPH JACOB

A REMARKABLE PLANT OF GARRYA ELLIPTICA IN THE BOTANIC GARDEN, CAMBRIDGE.

Saxifraga burseriana.—Mr. Raymond Negus, whose note appeared on page 90, February 21 issue, is to be congratulated on his success in growing this very interesting plant, and I am glad to have the opportunity of supporting his method of cultivation by personal experience. Until last year I grew *S. burseriana* and its allies in shade; but since trying them in full sun my plants have increased in size and have flowered more freely. Mr. Negus may well feel proud of his plants with thirty flower-spikes on each, but it is to be hoped that he saw Mr. Frank Lloyd's plant at Vincent Square on the 24th ult. This plant, it was stated, bore over three hundred flowers, and although I did not count them, the dense mass of bloom gave strength to this statement. It would be interesting to hear from the grower how this result was obtained. From personal observation of my plants, I have come to the conclusion that there is practically no difference discernible between the type and the varieties Gloria, major and magna. Given approximately the same number of flowers on a plant of each, grown in the same way side by side,

spits and bringing the lower soil up to the surface each time. Last year the peat moss manure was just dug in for certain vegetables one spit deep. The result upon early Potatoes was satisfactory, but the presence of small white mites was noticeable in the tubers. For midseason and late Peas I usually prepare trenches, and in these the peat moss manure was dug in a spit deep. The Peas germinated freely, and looked well until the growth was about six inches high, when the foliage and stems turned brown and died. Several rows behaved like this. Upon examination I discovered that the peat manure around the roots was infested with mites, as were also the roots and stems of the plants. The plants, apparently, were all right until the roots came in contact with the manure. Evidence that the manure was responsible for this was the fact that other rows of Peas which had straw manure were quite satisfactory and growing on the same patch of ground. I may also add that others in this district experienced the same trouble where peat moss manure was used, and good results where they had also used other manure. Our

Crocus Sieberi in Essex and Scotland.—I was rather surprised to see that *Crocus Sieberi* was no further forward in an Essex garden the other day than with me in the south-east of Kirkcudbrightshire. In ordinary seasons there would be from a week to a fortnight's difference between the two. *C. Sieberi* is one of the best of the early *Crocus* species, and ought to be much more cultivated for its purple flowers. It is now very cheap, and should be planted in quantity.—
ARNOTT, *Maxwelltown, Kirkcudbrightshire*.

Canker in Fruit Trees.—I quite agree with "E. M.," page 78, issue February 14, in his remarks on the cause of canker in fruit trees. I have cured very bad cases of canker, mainly by dealing with the roots. I will only refer to one case now. A half-standard of Cox's Orange Pippin was very badly cankered. I was asked to try to cure it. We took out a trench, cut off the main roots permeating the cold, clayey subsoil, and burrowed well under the tree; then filled the trench with lighter loam and plenty of grit. The canker was so bad at the junction of the head branches with the main stem that one could see through the holes. All the cankered part was cut away and the wounds dressed with undiluted air tree oil. The stems healed, the bark grew healthily and covered the holes. The tree bore a heavy crop of handsome fruits the following year, and did not suffer from canker afterwards.—G. G.

—A most interesting article, of great value to all fruit-growers, appeared on page 56, in the issue of January 31. Having very much of this canker to deal with, I can only add that I find Stockholm tar the best for healing the canker wounds after cutting out the disease. The canker is very far-reaching, as in many instances, when cutting off the diseased shoot, I have to make it still further cut, as the canker is so plainly seen in the wood when cut. As a wet season develops the spread of the disease, and knowing that in our silty soil the roots run down, I have done much root-pruning to advantage. I might here say that I find our underground soil, or, rather, it, in a wet year, excessively wet, almost a running sand—poor indeed for top fruits—yet we do fairly well by feeding with basic slag, &c., avoiding stable manure. There is not the least doubt the free use of the latter does encourage the free wood growth, which, being difficult to open, is a ready prey to canker.—STEPHEN CASTLE.

—I have read with interest the remarks by "Scientist" and "E. M." on this subject. "Scientist" points out the danger of subjecting the trees to attacks by the breaking of the bark through carelessness in gathering fruit, pruning and other work. But from experience in this particular place the larger trees seem to fare best. Small pyramids and young trees that one can gather fruit from and prune without damaging are attacked much more severely. I were to cut out every bit of canker or diseased patches, certainly I should have many useless stocks, whatever may be thought of a cankered tree. It would cause me to begin afresh every year. I prefer to check if possible, and help Nature to heal, rather than do too much cutting and removing. I quite endorse the remarks about being careful to keep the bark sound, and one cannot be too careful against insect attacks. A few years ago a case came under my notice that was perhaps, worthy of quoting. A cottager had a standard Apple tree badly cankered about four feet from the ground. After removing thoroughly the diseased bark and decayed wood, he

applied Stockholm tar, and then placed a bandage around to assist protection. Whatever may be the experience of applying tar as a remedy, that particular tree to-day is healthy and fruitful. I have Ribston Pippin and Cox's Orange Pippin cankered slightly, while Lord Suffield, Reinette du Canada and Belle de Pontoise are almost killed. With regard to "E. M.'s" note, the soil here corresponds exactly; but I notice that certain varieties canker worse on certain stocks. Longfield (Canadian), a never-failing cropper, cankers worse on the free stock than on the Paradise stock. Baldwin seems useless on any stock in this neighbourhood. North Star on the free stock does fairly well; on the Paradise stock it is almost worthless.—J. J. G., *Penzance*.

—Permit me to record my experience and conclusions re canker in the Apple tree. "Scientist" (page 56, issue January 31) and "E. M." (page 78, issue February 14) have each, from different standpoints, diagnosed the cause, and suggested the cure for this common disease. While accepting in the main "Scientist's" theory, I am disposed, from my own experience, observation and reading, to say that "E. M." is on the true lines as to the origin of this mischievous pest. My knowledge of the disease points to the conclusion that soil has a very considerable influence in inducing canker. The majority of practical gardeners, while always grateful to scientists for their research and discoveries, have to be content to know and act according to mere elementary principles. Those principles are discovered in practice. "E. M." has noticed that certain causes produce certain effects. Reasoning from effect to cause, he concludes that a water-logged clay soil is apparently a predisposing cause of canker. I wish to state that it is my opinion also. Whatever may be true as to "Scientist's" theory of canker, its cause and cure, it seems to me that anything in the constitution or condition of the soil which tends to lower the vitality of a tree will make it more liable to develop canker. I have charge of a garden, closely surrounded by trees on the east, south and west. The soil is a stiff heavy clay, resting on an undrained subsoil of blue clay. In certain parts of this garden, no matter what variety of Apple I have planted, it eventually succumbed to the disease in question. As the healthy, vigorous person is found, as a rule, to be proof against tubercular troubles, so the robust, healthy tree is as a rule immune from canker. The tendency to tubercular affections may be mainly hereditary, but I am persuaded that the tendency to canker is to be found chiefly in root conditions. As the mere presence of fat is not evidence of robust health in the human being, so the fact of gross wood is not evidence of vigour in the case of fruit trees. Too much growth is, to the experienced eye, in some varieties of Apples a sure sign of a deficiency, and not of an excess of health. The lesson seems to be to make the root conditions right, if it can be done; but if it cannot be done—well, expect canker.—GEORGE JOHNSTON, *Ashfield Lodge, Cootehill*.

FORTHCOMING EVENTS.

March 9.—United Horticultural Benefit and Provident Society's Committee Meeting.

March 10.—Royal Horticultural Society's Bulb Show (two days).

March 12.—Manchester and North of England Orchid Society's Meeting.

March 13.—Beckenham Horticultural Society's Meeting.

DAFFODIL NOTES.

The New Poetaz.—It may be news to some readers to know that there exists alongside of the now well-known Poetaz of van der Schoot (Alsace, Elvira, Aspasia, Jaune à Merveille, Irene and Sunset, to name the six I think the best) another set, raised for the most part, if not entirely, in the village of Limmen by one Albert Vis, a sort of bulb recluse, at whose death a few years since they passed into different hands. I believe the exact knowledge of the cross from which he got his hybrids died with him, but it is said to have been a Poet fertilised with pollen of some of the Tazettas. This, it will be remembered, is the origin of what I must call, in contradistinction to these, the older Poetaz. If my facts are correct, it then becomes a matter of peculiar interest to raisers to know that the newer ones are of quite a different type in both habit and inflorescence, featuring as they do in stem, in height, in truss, in scent, and in individual flowers the Tazetta parent in a greater degree than those raised by van der Schoot at Hillegom. I have summered and wintered four of them for three years, so I feel I am in a position to pronounce judgment upon them. My verdict is that they are excellent as pot plants; and inasmuch as there are delightful combinations of colour to be found among them which are wanting in the older ones, I fancy they have a great future before them. Distinction, a fine, large-flowered variety with a pale red cup and soft yellow, undulating perianth, with a fair number of blooms to a truss; and Albert Vis, which has a big rich orange eye in the centre of a well-proportioned pure white perianth, and with a smaller quota of flowers to a stem than is found in the above-mentioned Distinction, were both to be found in some retail lists last autumn, so that I hope someone who has bought them will give us a note in THE GARDEN as to his experience with them. I have also grown Orange Blossom and Orange Cup for the same number of years as the preceding. The former is a long-stalked Albert Vis, but in other respects very similar. The latter is on the lines of Distinction, but the cup has a real red edge, which is doubled, puckered and pleated in a way that at the moment I cannot recall in any other Narcissus or Daffodil.

Thanks to the kindness and courtesy of Messrs. M. van Waveren and Sons, I have been able to increase my collection this spring, and I am now busy making the acquaintance of some of the others of this new race. Of these I will write in my next notes, when all the different varieties have flowered. Visitors to the "Midland" last year will remember a collection of them from Mr. H. Prins of Lisse, but they were so badly set up and so out of condition that they did not do themselves justice. Moreover, they had been grown in the open, I expect, and they are not at their best then.

Daffodils in New Zealand.—Of course, one has known what a voracious appetite these two islands have had for years for new varieties, and that lately the pangs of hunger have been partly assuaged by home-grown food; but since the publication of the Daffodil Year Book I have become aware that I under-estimated both the one and the other. I am hoping to include two or three articles upon what is going on "down there" in the 1914 edition. The following extract from an article in one of the New Zealand papers by a very keen and successful amateur, Mrs. Maclean of Oamaru, who visited three of the chief shows last spring

(that is, last September and October), will be of interest, and, I hope, will not unduly depress my "Sic transit gloria mundi" friend at Rye. After dealing in detail with each show, she thus ends: "Comparing the three shows, there is not the slightest doubt but Oamaru leads so far as excellence of cultivation is concerned. Naturally, a much larger number of the latest and most expensive varieties are shown in Dunedin and Christchurch, and these, of course, take the eye; but where the same variety is grown and shown at each show the Oamaru flower is the best, and any exhibitor who can secure honours at Oamaru need not have any fear of competing with every prospect of success at either of the other shows. Locally, the season seems to have suited Barris and incomparabilises with red in the cup, as was evidenced by the many flowers of these divisions which were exhibited here (Oamaru) in perfect condition. New Zealand seedlings compare more than favourably with imported flowers so far as size is concerned, and when colour and form of

took place fifty-eight years ago, I feel it is unlikely that anyone is living who can enlighten us.

Daffodils from Sweden.—Has anyone in England done what I have done this last month—had Daffodils in their greenhouse that had been grown last year in Sweden? Hearing that a philanthropic lady there—the Lady Sigrid Stjernsward—had started a Daffodil farm at Widtsköfle in Scania some four or five years since, I wrote for some bulbs, and before long a couple of packages arrived by parcel post, which contained samples of some of the better-known varieties in commerce. Part I potted up and grew them alongside of my others; part I planted in the garden. All of the former have now bloomed, and they have been carefully compared with the same varieties from other sources. Mrs. Langtry, Barri conspicuus and princeps were decidedly weak in growth and bore few flowers; whereas Empress, Sir Watkin, ornatus, Golden Spur and Queen Bess were all very good, and quite up to either English or Dutch grown bulbs; in fact, in the

SEASONABLE WORK AMONG THE ROSES.

It is not too late to plant Roses if a little extra care is taken. I have often had even better results from spring planting than when done during the midwinter months. One of the chief points is to have everything ready, and so avoid any unnecessary exposure of the roots, which, in many cases, will be more or less active and easily affected by a drying wind or sun. Pruning will be dealt with fully in a week or two, but I may say it is better in all cases to prune newly planted Roses down close, and, this being the case, you will have little, if any, wood exposed to drying influences, which will be a great help to the more uniform advance of both roots and top growth. Avoid getting upon freshly moved ground if it is wet. Use a few boards if it must be done, but it is far better to delay the work for a few days. As a further

help in not treading until the soil has become dry and more settled, I would prune before planting in spring. At the same time, the soil should be fairly firm around the roots and base of the plants. Should you be planting standards, do not fail to afford some efficient support at once. They must have it the first year, and it is a pity to allow them to sway at all, which cannot but do harm to and strain the newly forming roots.

As one looks over his Roses at this pruning-time a few blanks will probably be found in the beds and borders. Too often one does not take enough care in replacing these. Let a better preparation be made by moving more soil and making a slightly larger hole. The slight injury to its neighbour's roots will not matter, and it will be a better start for the new-comer. When pruning pegged-down Roses, do not miss the opportunity to feed by mulching and top cultivation of the soil before laying the young wood down again. You will not have such a good chance again during the whole season. Mulching generally may be done after pruning, and will still be in ample time to feed the roots at the period they

most need it. A properly mulched Rose bed or border in which the trees have been pruned has a pleasing and promising look, while it needs no more attention for a considerable time. I may say that Roses are by no means so particular as many other subjects about the class of manure they receive, but the best and its application has been frequently treated of in these pages. I only hint that now is a most seasonable time to use this.

Under glass our plants should be in full growth, and will need free waterings of weak liquid manures. I am firmly convinced that many checks to growth and other partial failures are caused by the use of overstrong liquids. It is far better to spread the same amount of stimulant over double the number of applications than run the risk of injury to the tips of healthy growing roots. But it is one of the most common errors. Simply because the plant is doing well it does not want a strong dose of liquid manure to maintain its vigour; much better feed steadily and more often.

A PAN OF SAXIFRAGA BURSERIANA WITH OVER THREE HUNDRED BLOOMS.

an equal standard are produced here, there will not be any doubt as to which are the better flowers, but at present the home-grown ones are ahead in these qualities, and, after all, perfect form and colour are superior to size."

A Prehistoric Exhibit.—From March, 1851, to March, 1859, there existed an influential society called "The National Floricultural Society." Quoting from the "Address" in Vol. I., Part I., it was formed to supply the want of a "tribunal to test new Florists' flowers and hybrids." On looking over its Transactions, I found, under the date of April 24, 1856, this entry:

"The following were the subjects of exhibition:
"Azalea from Mr. E. A. Hamp.
"Auriculas from Mr. C. Turner.

"Narcissi from Mr. Leeds," &c.

Unfortunately for us, these seedlings received no award, or otherwise we would have had their names and descriptions, and as this exhibition

case of Queen Bess, superior. Five bulbs bore ten fine blooms—better I have never seen. All the above flowered at the same time as Dutch-grown bulbs.

JOSEPH JACOB.

A MAGNIFICENT PLANT OF SAXIFRAGA BURSERIANA.

A GOOD deal of interest was centred around a remarkably well-grown pan of Saxifraga burseriana which gained a cultural commendation at the last meeting of the Royal Horticultural Society. Over three hundred blooms were crowded together in a profuse mass, almost covering up the dense rosettes of foliage. It was shown and grown by Mr. F. Lloyd of Croydon, who for some years has grown alpine plants, notably Saxifrages, with marked success. The magnificent specimen which we illustrate above reflected great credit upon the cultivator, and well deserved the cultural commendation bestowed upon it.

Insects, too, will probably be more trouble as the season advances. Here, also, too severe measures, with an idea of immediate effect, are altogether wrong, and not infrequently do as much, or more, harm than the enemy itself. Use weaker solutions and be more persistent in your washings, and you will have better results combined with safety.

The need for ventilation should be avoided as far as possible by a careful regulation of fire-heat, and I am sure much ventilation might be made unnecessary if a little more thought was used in this direction. Mildew is sure to trouble you if you vary the temperature much and allow the slightest draught. Much benefit has been found here by dissolving a little extra flowers of sulphur in the washes generally used. If the solution is kept well on the move, as it should be, you will find a very light and unsightly dusting of sulphur left both above and below the foliage. This is not only harmless, but is a good preventive, and need not be used except to leave the faintest dusting of sulphur upon the foliage.

Sussex.

A. P.

THE JAPANESE MAPLES.

THE various forms of Japanese Maples, or *Acers*, are always popular in gardens by reason of their dainty, elegant leafage and brilliant colouring. Even in cold districts, where they are not a success out of doors, people often grow them in pots or tubs to stand in a conservatory or greenhouse during spring, for their prettily tinted leaves at that period make them invaluable for grouping with forced shrubs, bulbs and other plants. Then, towards May they are stood out of doors, to be placed in the conservatory again in autumn for the few weeks during which their leaves are gay with brilliant autumn tints. The *palmatum* group is divided into several sections, according to the lobing of the leaves. The *septemlobum* section may be recognised by reason of its leaves being considerably larger than those of others in the group. They may be as much as 5 inches long, exclusive of the stalk, and 4 inches wide. The number of lobes into which the leaves are divided varies, but is usually from seven to eleven, and they are divided almost to the base. Each lobe is again prettily cut. The colour of the leaves varies on different plants almost as much as the lobing, and for this reason distinctive names have been given to the various forms, such as *atropurpureum*, *bicolor*, *elegans*, and *elegans purpureum*. In spring the colour varies from bright bronze to greenish bronze or pale green, and in autumn from orange scarlet to scarlet and deep red. In the South and parts of the Midlands the Japanese Maples thrive satisfactorily in a sheltered part of the garden, but in many parts of the North they are not recommended for outdoor work. In West Lancashire good specimens are sometimes seen in the open.

D.

SEASONABLE NOTES ON AURICULAS.

WITH the arrival of March some of the early varieties show signs of flowering, and it is essential that sufficient protection be given to keep out frost. The grower must study the weather, and not be taken off his guard by bright, sunny days, because these are often followed by several degrees of frost at night. Some cultivators remove the plants that are pushing up their spikes into a cool, low house; but even a small quantity of fire-heat will sometimes draw the plants and the scapes, which render them very unsatisfactory from a decorative standpoint. Before the first flowers open I always like to vaporise the frame to kill any green fly that

and are considered by some to be more easily grown than the show varieties.

The Fancy Auricula.—Seedlings which cannot be arranged in either of the show classes previously mentioned, but at the same time possess certain good qualities which make them worth growing, are referred to as fancy Auriculas.

Exhibitions.—Next month I shall give a few details on preparing the plants for show. In the meantime a schedule should be procured, the classes selected and the plants watched, so that they are in full beauty on the day required. If they are coming on too fast, a north position should be chosen, and the lights removed whenever the weather is mild and dry. T. W. BRISCOE.

MAGNOLIA STELLATA.

To *Magnolia stellata* belongs the distinction of being the first *Magnolia* to open its flowers. It

THE FIRST MAGNOLIA TO BLOOM (M. STELLATA).

may be on the plants. The operation is not required again till the flowering season is over.

Types of the Auricula.—There are two distinct sections of Auricula—the garden kinds, derived from *Primula Auricula*, and the alpine varieties, from *P. pubescens*. The latter group contains some of the most beautiful tints and shades, while the former are often covered with a delicate meal or farina. These are known as show Auriculas and are divided into four sections, viz., green edge, grey edge, white edge, and selfs. The first three are very beautiful, but I am afraid they are not grown to the extent that their merits deserve. The selfs are a class where the colour extends from the paste to the edge of the petal, and are, in consequence, very attractive, while in some instances the foliage is densely coated with farina. Although the selfs are largely grown, the premier place in regard to popularity must be awarded to the alpiners, which are devoid of all meal or farina either on the leaves or flower

is a deciduous species, and the blooms open before the leaves unfold. Sometimes the flowers suffer for this earliness in being cut down by spring frosts. In a mild spring, however, there is no shrub more beautiful, for on a bright, sunny day the fragrant flowers light up the surrounding landscape with telling effect. It is a native of Japan, and is often cultivated in this country under its old name, *M. halleana*. Like other *Magnolias*, it is a little fastidious about soil and situation, showing a marked preference for a light, loamy soil of an open nature and a warm position sheltered from strong winds. It should be borne in mind that *Magnolias* resent disturbance at the root more, perhaps, than any other class of plants. When transplanting has to be accomplished, it is best done in the spring, immediately after flowering and as new growth commences. The fine fibrous roots require very careful handling, while, after planting, the shrubs should be sheltered under mats and freely syringed if the weather is dry.

STOCK BEAUTY OF NICE.

Of all the gorgeous array of annuals, few can equal the Stock, and of its many varieties Beauty of Nice must, I think, be awarded first place. This variety can be had in bloom at almost any season of the year, and where a large quantity of cut flowers is required, it is invaluable, as it blooms in about three months from the date of sowing, lasts exceptionally well in water and, above all, has a perfume with which few other flowers can compare. I find it most useful under glass for giving cut blooms in early summer, when the bulbs and spring flowers are all over and the summer flowers not yet in bloom. In this cold climate I sow about the middle of February to have the blooms ready about the end of May, but those who are situated in a warmer spot would do better to defer sowing until the end of the month.

Its cultivation is very simple, and I have adopted the following method with great success. Sow the seed thinly in pans of very sandy soil, just covering the seed with a sprinkling of sand, and place the pans in slight bottom-heat until germination takes place, which will be in about eight or ten days. When the young seedlings appear, stand the pans on a shelf near the glass in a cool house and grow on steadily, taking care not to weaken the young plants by forcing. As soon as they are ready, prick them off three into a 3-inch pot, using a light, rich compost. Care should be taken not to discard the weaker seedlings, as these invariably produce the double flowers. As soon as the young roots come to the sides of the small pots, repot into 5-inch or 6-inch ones, the latter preferably, in which they will flower. A compost consisting of two parts good fibrous loam, half a part each of leaf-mould and well-rotted manure, and sufficient sharp sand to keep it porous, will be found most suitable for the final potting. If any bone-meal is at hand, a sprinkling of this can be added, with only the best results. When the flower-buds appear, frequent doses of liquid manure are necessary to produce large spikes, and a rich top-dressing well repays any time and trouble spent in applying it. To produce the best results, a cool but steady temperature is necessary, hard forcing at any period being highly detrimental to the production of good spikes.

One word of warning when buying the seed: Go to a reliable firm and be prepared to pay a reasonable price for it, as only the best strains will yield a high proportion of double flowers. I personally like the pink variety best; but seed can also be had of yellow, white and mauve, and is simply a matter of taste. I am sure that anyone who buys a packet of good seed and gives the plants

a fair chance will be rewarded with a quantity of the sweetest blooms, which in beauty of form and fragrance are unsurpassed by any other annual.

Troon, Ayrshire.

AN AMATEUR.

A COOL GREENHOUSE HEATH.

ERICA MELANTHERA.

This is beyond doubt one of the most profusely flowered of all greenhouse Heaths. The flowers are usually white or tinged with pink, but the distinguishing feature is seen in the prominent black anthers seated in the centre of each tiny

ERICA MELANTHERA. AN EASILY GROWN HEATH FOR THE COOL GREENHOUSE.

flower, a peculiarity which has earned for this Erica the title of the Black-anthered Heath. The flowering season is from autumn till spring, and in the depth of winter pot plants, compact in growth and smothered in bloom, are sent in thousands to our leading flower markets, this being certain proof of the popularity of *E. melanthera*, if such were needed. The chief point to observe in its cultivation is that it resents a warm temperature. A cool greenhouse will suit its requirements throughout the flowering season, while in the summer-time the plants should be placed in unheated frames from which the lights are raised or removed on all favourable occasions.

SOME BEAUTIFUL ANNUAL FLOWERS.

THE NEMESIAS.

THE time for deciding what is to fill our beds and borders in the summer is now at hand once more, and I should like to advise amateurs to give *Nemesias* a trial. There are, I am sorry to say, only too many who have never had the pleasure of growing these lovely annuals, and I am sure the only reason that can be given is that they do not know what *Nemesias* are capable of doing. For making a brilliant display I know of nothing to surpass them, and the flowering season extends over a much longer period than that of the majority of flowers. Being half-hardy annuals, they require a little heat to assist germination if sown early in the year, but this is not essential if sown later on.

Their cultivation is simple, and I have always found the following treatment very successful: About the middle of March take some well-crooked pans and fill to within an inch of the rims with a light compost containing a good percentage of old leaf-mould. Over the surface sprinkle a layer of very fine soil, and on this sow the seed very thinly. Just cover over with fine soil or sand and place in gentle heat. Cover each pan with a sheet of glass and keep well shaded until germination has taken place, when the young seedlings must be gradually exposed to the light and air. Great care must be exercised in watering, as negligence in this respect will cause the seedlings to damp off wholesale. As soon as ready, prick them off into boxes about two inches apart each way, using a slightly stiffer compost than before. Place over the crocks a good layer of very old manure to keep the young plants well nourished until they are planted out. Grow them on in gentle heat until they have made nice little specimens, when they must be gradually inured to a cool temperature, as this is necessary to keep them robust and strong. About the end of April they can be safely transferred to cold frames which have been filled

to within a few inches of the glass with good soil enriched with leaf-mould. The latter half of May is the best time to plant them out in their flowering quarters, and the beds must be well enriched with a liberal dressing of manure. They should be well dug and the manure thoroughly mixed with the soil some time before planting out, so that they may have had plenty of time to settle down to their normal level.

Those who wish to give these annuals a trial, but have not a heated greenhouse at their disposal, can raise a fine batch of plants by sowing the seed in cold frames about the middle of April. Keep close and well shaded until the young seedlings

appear, when they must be given a little air to keep them sturdy. The after-treatment is the same as previously described, and watering must be done with great care. If a spell of frost should come, throw some mats over the frames, and these will keep all safe. These plants will not, of course, flower quite so early as those raised in heat earlier in the year, but when the flowers do come they will be every bit as good. When the young plants are well established in their flowering quarters, give weak doses of liquid manure, and, should the weather be very dry, a mulch of old manure will be found beneficial, and will considerably prolong the season of flowering.

Most people prefer the mixed colours, chiefly, I think, because the shades are so numerous and varied and all blend so well together. There are, however, blue, orange, white, and crimson varieties which come true to colour from seed, and all are very beautiful, especially the blue, which is a lovely pure shade. A good strain of seed is essential, so when buying it go to a good, reliable firm and be prepared to pay a reasonable price for it. Amateurs would do well to try these lovely annuals, and I am sure they will be delighted with the glorious display of colour which a mass of *Nemesias* produces.

Ayrshire.

G. B.

HARDY CHINESE PRIMULAS.

(Continued from page 108.)

P. helodoxa (Balf. fil.).—This promises to be a most valuable plant. It belongs to the *Candelabras*, and has all the good qualities of *P. Bulleyana*. It is of strong growth and bears handsome scapes of whorls of dark yellow flowers in many tiers. It was collected for Mr. J. C. Wilson, Caerhays Castle, in 1912 by Mr. Forrest. It requires the same treatment as *P. Bulleyana*.

P. Knuthiana (Pax).—This has but recently come into cultivation. The flowers are lilac or lilac mauve. It resembles *P. frondosa*, but is more difficult to grow. It belongs to the *Sertulium* section.

P. Littoniana (G. Forrest).—This most distinct member of the *Muscaroides* section does well with me in pure pulverised loam in a well-drained, shady position. If a piece of glass is placed over it during the winter, it will prove perennial. Unless pollinated it does not seed here, but if that is done it seeds freely. A most handsome and striking plant, with its long spikes of flowers, sometimes 6 inches long, with scarlet bracts and lavender or rose lavender flowers. Collected by Mr. Forrest in the Tali region and introduced in 1908 by Messrs. Bees, Limited.

P. Maximowiczii (Regel).—A strong-growing, fragrant species collected in North China by Mr. Wilson and introduced into cultivation by Messrs. Veitch in 1906. The leaves are distinctly petiolate, from 3 centimetres to 5 centimetres long, narrowly elliptical, acute and denticulate. The scape is from 20 centimetres to 40 centimetres in height, and bears in May a many-flowered umbel of small, dark purple or, in some cases,

brick red flowers. I had this plant growing luxuriantly in the open border, but, as it has died, I think that it must be only half-hardy. Cultivation: Should be grown in a cold house in good loamy soil in full sun.

P. nessensis (G. Forrest).—Introduced in 1911 by Messrs. Bees from seed collected by Mr. Forrest. It has pretty flowers of cherry pink in moderate-sized heads. It comes from Yunnan, and belongs to the *Denticulata* section. This is the plant which is being sent out by Bees, Limited, under the name of *Primula farinosa* Beesii. Cultivation: Treatment similar to *P. farinosa*.

P. pinnatifida (Franch.), a beautiful little plant with blue flowers, has not proved hardy with me in the open, but in a cold house it should be satisfactory. It belongs to the *Muscaroides* section.

P. Poissonii (Franch.), of the *Candelabra* section, has been in cultivation since 1890, introduced by the Jardin des Plantes, Paris. It resembles *P. angustidens* in many ways, but has

P. pulverulenta (Duthie).—Introduced from West Szechwan by Messrs. Veitch in 1908, this *Candelabra* *Primula* has become a general favourite. It is a plant for every garden, and grows from 2 feet to 3 feet high in rich, moist soil. It has crimson-purple flowers in whorls. It seeds freely, but the lovely white variety Mrs. Berkeley fails to do so with me (see page 42, issue January 24). Cultivation: Good rich garden soil in half shade. The illustration represents a fine colony of this beautiful variety in Messrs. J. Veitch and Sons' Coombe Wood Nursery, and is from a photograph by Mr. R. A. Malby.

P. pycnoloba (Bur. et Franch.).—The sole known member of the section *Pycnoloba*. This species has a cluster of flowers, with a long, creamy, membranous, wide-mouthed horn, filled at the mouth by the small, dark red corolla. It has hairy leaves, with petioles, and is hardy if it is protected by a sheet of glass from winter moisture. Collected by Mr. Wilson in Central Szechwan and introduced by Messrs. Veitch in 1906.

A BEAUTIFUL GROUP OF PRIMULA PULVERULENTA MRS. R. V. BERKELEY.

shorter and broader leaves, and the flowers, which are fewer in number, are larger and of a deeper purple. *P. Poissonii* has not proved hardy with me, but it is so in some parts of England and Ireland. Cultivation: Good rich soil in damp situation. Half shade.

P. pulchella (Franch.), of the *Nivalis* section, with blue or purple flowers, is very beautiful, and seems to be fairly hardy. It is not yet in the hands of the public.

P. pulchelloides (E. K. Ward) belongs also to the *Nivalis* section. The leaves and stems are covered with yellow farina. The slender flower-scape rises well above the leaves and carries at its summit a number of pale lilac flowers. Both *P. pulchella* and *P. pulchelloides* owe their introduction to Messrs. Bees in 1911. Cultivation: I have no experience of this in the open, but in pots in a cold house it does well as a pot plant in well-drained gritty soil.

P. septemloba (Franch.).—Introduced in 1906 by Messrs. Bees, Limited, from seed sent by Mr. Forrest. The leaves are lobed like a *Geranium*, as are all the members of the section *Geranoides*, to which this species belongs. In most of its characteristics it resembles *P. Gagnepainii*, but with me it has not proved hardy in the open.

P. sibirica will be dealt with under Himalayan species.

P. sinolisteri (Balf. fil.).—An interesting micro-form of *P. obconica*, sent out as *P. Listeri*, but not that species which is Himalayan. It is barely hardy with me, but should be so in the South. The reniform, orbicular leaves have not the irritant hairs of *P. obconica*. There are two forms, one white flowered, the other pink. *P. sinolisteri* is very free-flowering. Cultivation: Should be treated in the same way as *P. obconica*.

P. Veitchii.—One of the hardiest of all garden *Primulas*, *P. Veitchii* came from West Szechwan

in 1906, and was introduced by Messrs. Veitch through their collector, Mr. Wilson. It grows well in ordinary soil, and gives an abundance of magenta flowers on stems 18 inches or so high. It belongs to the *Cortusoides* section and has handsome leaves.

P. vittata (Bur. et Franch.).—I think the true *P. vittata* (with which may be discussed *P. secundiflora* as closely resembling it) will only prove half-hardy. *P. vittata* was introduced in 1905 by Messrs. Veitch from seeds sent by Mr. Wilson. It has elongated, erect leaves and drooping pink-purple flowers, with a white mealy band to the calyx. It is rare in cultivation, and what we see in gardens masquerading under the name is *P. angustidens*, a plant which it in no way resembles. *P. secundiflora* was collected by Mr. Forrest and introduced by Messrs. Bees in 1908. It has oblong-elliptic leaves, horizontal in a rosette. *P. secundiflora* does well with me in a cold frame, but whether it is hardy during the winter in cold districts I am not prepared to say.

JOHN MACWATT.

Morelands, Duns.

THE CULTIVATION OF ASPARAGUS.

THIS is one of the most important vegetables, and one that does not receive as much attention as its merits deserve. In some gardens the same roots will last in a satisfactory condition for twenty years without renewal, while in other parts the beds require making often. The most suitable soil is a deep, friable loam with a porous subsoil, as this does not require much preparation. Deeply dug and well manured, it will last for years in good condition if yearly attention is given to the addition of suitable manurial stimulant. The soil which requires the most preparation is that which is naturally heavy in character, some 18 inches or 2 feet deep below which is a hard pan of clay-like matter almost impervious to water. If this is not broken up to a considerable depth to allow water to pass away quickly, the succulent Asparagus roots suffer a check, and under such conditions cannot grow vigorously, as they should to produce heads of the desired quality.

Treatment of Poor Soil.—The best method of bringing such soil into a suitable condition would be to remove some of this hard pan of subsoil, replacing it with lightening material when trenching is proceeding, and this should be done at least 3 feet deep, or, all the better, 4 feet, replacing the soil in the same position as it was found. The bottom spit or base should be broken up a foot deep.

The Size and Shape of Beds.—In unsuitable soil it is best to form beds 4 feet wide, keeping them a foot above the ordinary ground-level to ensure effective drainage. Where the soil is

naturally of a drier character, with a well-drained subsoil, special beds are not at all necessary; the plants can be equally well grown in rows 2 feet apart, thus requiring no alley space.

The Best Plants.—The common practice of forming beds of Asparagus is to purchase two year old plants from the open ground, carefully putting them out in April. A much better plan is to sow two seeds in a 3-inch pot in sandy soil during the first week in April. Stand the pots in a cold frame, shading them from bright sun and keeping the frame close to hasten germination. Directly the plants appear above the soil, remove

When to Plant.—The first week in April, when the plants are on the move, put them out in rows with a trowel, covering the crowns 2 inches with a compost of old potting soil, decayed leaves and wood-ashes to encourage quick growth. Allow a space of 15 inches between the plants, which will provide ample room for development. Should the weather set in dry, keep the surface soil freely stirred to conserve the moisture. As the growth progresses support the "grass" if it is liable to be bent or broken by strong wind. The second year will see much progress, and every encouragement should be given to induce growth. Liquid manure applied freely will have considerable influence on the subsequent progress of the plants, and frequent stirring of the soil will also assist in that direction.

E. M.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Sparaxis King George V.—A brilliantly flowered sort of robust habit that should prove popular with all. In point of brilliancy it is akin to Fire King, which gained an award of merit in June, 1902. The new-comer, indeed, may well be described as a vigorous variety of that kind, and as such it will be welcome. The dominant colour of the petals is crimson-scarlet, richer scarlet near the tips, the whole in striking contrast with the deep golden colour of the tube of the flower. Shown by Messrs. Barr and Sons, Covent Garden, W.C.

Freesia Excelsior.—A novelty of the first water; a plant possessing the vigorous growth of a Montbretia. For the sake of comparison we might refer it to a glorified *F. Leichtlinii*. The handsome, erect flowers, of remarkable substance, are coloured a rich cream, with faint touches of orange on one side of the tube. Vigour, substance of flower and marked fragrance are among the best attributes of *F. Excelsior*, which came from Messrs. Sutton and Sons, Reading.

NEW ORCHIDS.

Foremost among new Orchids is the immense *Odontoglossum Colossus*, with heavily blotched chocolate flowers from 4½ inches to 5 inches across. This is one of the largest, if not the largest *Odontoglossum* yet raised; the petals are 1½ inches

broad, with white frilled margins. The plant carried four blooms. Its parentage is unknown. Shown by Baron Bruno Schröder and awarded a first-class certificate. A similar award was granted to *Cymbidium Alexanderi* Hamilton Smith's variety, having neat ivory white flowers with a scarlet crimson lip. Shown by Mr. Hamilton Smith, Finchley. Awards of merit were granted to *Cypripedium Mogul* and the golden orange *Laelio-Cattleya Ariel*, both shown by Lieut. Colonel Sir George Holford; and to *Phalanopsis Ariadne*, shown by Messrs. Sander and Sons.

The foregoing awards were made by the Royal Horticultural Society on February 24

ODONTOGLOSSUM COLOSSUS. A BEAUTIFUL NEW VARIETY WITH VERY LARGE AND HEAVILY MOTTLED FLOWERS. (*Much reduced.*)

the shading, gradually giving air to induce sturdy growth. When it can safely be determined which is the strongest plant, remove the weaker, as one in each pot is sufficient, and eventually remove the frame-light altogether. When the plants are a few inches high, plunge the pots in ashes at the foot of a north or west wall, which will keep the roots cool during the summer and lessen the necessity for applying water, though any neglect in this respect will prevent that steady growth which is so desirable. Here the plants may remain until the following April, gradually reducing the water supply as the "grass" ripens off.

GARDENING FOR BEGINNERS.

SOME EASILY GROWN WALL PLANTS.

THE title of the text here chosen carries with it more than a suggestion that not all the plants which from time to time may be found upon walls are alike easily grown or established.

To some extent the deduction would be true, though not absolutely. Given the right kind of wall and a selection of plants to suit its special requirements, quite a large number of the subjects planted would eventually become a complete success. Quite naturally, of course, there is considerable diversity among the plants themselves—the slow growing and the quick, for example—though we must not allow such differences to create a wrong impression in our minds, since the minute-growing alpine may require neither more nor less care than a plant such as the Aubrietia, which is of much freer growth. The real difference is one of inches against yards; and those of the latter set, catching the eye by reason of the superabundance of their growth, appeal rather to the unthinking as the more easily grown. At the same time, if we view the matter closely, such exuberance will be found to be nothing more than the limitations of the plant's development, that phase of it in particular with which the subject has been endowed by Nature. Such growth is on all fours with the giant and the dwarf, the Tom Thumb Snapdragon, for example, taking as long to reach the flowering stage as its taller relative 3 feet or 4 feet high. Why it should be so is not quite clear. But this we know: that such things occur abundantly in both the animal and the vegetable kingdom, those of the latter affording the gardener greater opportunities for embellishing phases of gardening that otherwise would perforce have had to remain unadorned for all time. In no department of gardening is this more true than wall gardening, the vigorous and free-growing subjects one has now in mind providing material for ornamenting the roughest walls or embellishing as with Nature's hand old ruins or rocky places wherever they occur.

To what extent such places may be ornamented may be gathered from the white Arabis on the roadside wall in the accompanying illustration, and though certainly one of the freest, is also one of the easiest plants to increase. Every scrap of it getting into touch with damp soil will root, and in a couple of years form sheets of trailing greenery, for a long time in spring and early summer beautified by miniature Stock-like spikes of almost snowy whiteness. It is a plant for the roughest of rocky places or rudest walls, dwarfed, it may be, where the soil is scanty or poor, yet always flowering abundantly, and perhaps all the more prodigally owing to this. The best way of introducing so free-growing a subject is by means of freshly rooted cuttings as the wall is built, arranging them high up the wall so that the draping habit of the plant may receive fair play. Similarly rooted cuttings may be introduced at other times, though preferably in autumn or early spring, so as to ensure a firm foothold before the drought of summer arrives. A particularly good subject, far too rarely seen on rough walls, is

Corydalis lutea, whose elegant, Fern-like habit of growth and myriads of yellow flowers should

commend it to all. The plant is most profuse in flowering, is apparently at home in the smallest cranny or crevice, and grows and flowers apace. It is almost impossible to root cuttings of it, and seeds, which are not always plentifully produced, are the best means of introducing it. Another excellent free-growing subject best introduced by means of seeds is *Saponaria ocymoides*, which forms trailing masses of growths 3 feet or 4 feet long, smothered in their season with rose or pink flowers. The white form, *alba*, and *splendens*, with flowers more richly coloured than the type, both merit attention because of their free growth and flowering.

The Aubrietias.—These as a class are unequalled, whether for freedom of growth or flowering, hardiness or reliability; hence are good enough for all. So good, indeed, are they that one might be pardoned for suggesting an Aubrietia wall, than

named. There is also a value in Wallflower, Snapdragon, the Red Valerian (which gives brilliant sheets of colour on chalk cliffs), *Dianthus deltoides* and many more. Poppies and Thrift have a charm of their own, and so, too, has *Zauschneria californica*, which, coming late, is capable of brilliant effect. Nor can one overlook

The Great Value of Silver-leaved Plants, which, apart from their own intrinsic merit, perform, when rightly placed, an even greater service to other plants around. This is particularly true when arranged in near proximity to green-leaved plants, which they mirror into greater life by reason of the contrast they afford. Moreover, the silvery whiteness of these plants is enhanced by the drier conditions of soil and the proximity of stone. *Achillea umbellata*, *A. Clavennæ*, *Senecio incanus*, *S. argenteus* and *Sempervivum*

WHITE ARABIS OR ROCK CRESS GROWING ON A ROADSIDE WALL.

which, in its day, nothing could present a greater feast of colour. How the plants thrive in the smallest wall crevice is proverbial, so that, with a little encouragement, much might be expected of them. And they never fail. Moreover, they are free seeders, and are easily multiplied by seeds, division or cuttings; hence the supply is practically unlimited. To entirely mantle a wall with Aubrietias, it should be planted at more than one level to give effect to the object in view. Such a wall would be best if the face of it is rugged. All the same, the Aubrietias are good in isolated tufts, and gladden the eye by their rich or effective colour masses. Dr. Mules (richest violet), Lavender (a most delightful shade) and Fire King are all good, while the older forms of *deltoidea* are still as serviceable as of yore.

Iberis sempervirens is also a fine trailing plant, with white flowers, and perfectly hardy and enduring. Then one cannot omit such as *Campanula muralis*, *C. pusilla* and its varieties, these preferably for cooler places than those already

named. *arachnoideum* are all good, with *Cerastium tomentosum* for rough places.

Finally, to add a cultural note, it is important that spring-planted walls or seed-sown walls be carefully tended in the matter of watering till the plants have become established and capable of fighting their own battles. Watering should be so done that the soil is saturated, and in this way encourage the roots to penetrate the deeper recesses of the wall, where their safety will be assured.

If these few cultural hints are conscientiously attended to, and the plants named selected and planted with a reasonable exercise of common sense, many old walls and cliffs, that in a neglected state are more or less an eyesore to their owners, might be converted into beautiful features, and the expense would be very small indeed. When the beginner has mastered the cultivation of these simple, vigorous growing plants, he will find further interest in overcoming the subtleties of those that only the experienced can bring to perfection.

F. H. JENKINS

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

New Vine Borders.—Planting should not take place before the end of this month. By that time the soil should have been warmed through, and the young Vines will immediately start into growth. The soil should be carefully removed from the roots, and this is best done while it is in a moist condition. No fire-heat will be necessary. If the Vines were cut down in early winter, so much the better; but this must not be attempted now, or the Vines will suffer seriously.

The Early Muscat Vinery.—If the Vines were started in December, they will soon be showing flower, and during this period the temperature should not fall below 70°. Ventilate with caution, and do not allow the atmosphere to become stagnant.

Plants Under Glass.

Campanula pyramidalis.—Plants of this, having been wintered in cold pits, should now be examined, the surface soil pricked up, and a top-dressing of fine loam and bone-meal applied. Ventilate the pit freely, and as the season advances give frequent waterings of liquid manure. These plants when well grown are valuable for the conservatory during the summer and autumn.

The Conservatory.—Let this be kept as attractive as possible by the introduction of fresh batches of flowering plants, which may include Rhododendrons, Lilacs, Wistarias, Deutzias and Azaleas, as well as various kinds of bulbs. Plants which are being grown for Easter decorations should be given plenty of atmospheric moisture. Very little fire-heat should be necessary now, but it is well to have them in a forward state, so that there may be no mistake about the supply of such plants as Lilioms, Spiræas, Richardias and Solomon's Seal, as well as various kinds of flowering shrubs.

Fuchsias.—Old plants for summer flowering may now be cut hard back and placed in a temperature of 55° until numerous young shoots appear, and at this stage the old soil may be removed and the plants potted into a compost of turfy loam and leaf-soil, with a sprinkling of rough sand. Early struck cuttings may now be potted into 3-inch pots and plunged in bottom-heat. The syringe should be freely used and very little air given. Pot again as soon as the plants are ready, and place them in a temperature of 65°.

The Flower Garden.

Bedding Plants.—In the present month there is much to be done in the way of propagating bedding plants, both by seeds and cuttings. The stock of various plants, such as Coleus, Iresine, Lobelia and Ageratum, is easily increased by cuttings, which should be inserted in fine sandy soil as soon as possible. A gentle bottom-heat is a great advantage where large quantities are required. Seeds of many summer-flowering plants should be sown now, and these may include Godetia, Clarkia elegans, Nigella, Larkspurs and Antirrhinums for autumn flowering.

Plant Out autumn-raised Antirrhinums, Canterbury Bells and Sweet Williams in their flowering quarters. Gladiolus Childsii, G. gandavensis and G. brenchleyensis may also be planted now. If only for cutting, these bulbs should be planted on a border for the purpose, so that the flowers in more important situations may be left uncut.

Lawns.—During the present month it will be necessary to roll and sweep the lawns, trim the edgings and renovate the paths. Examine the drains so that the surface water may pass quickly away. All these things should be attended to as early in the month as possible.

The Rose Garden.—In sheltered situations some of the hardiest varieties may be pruned now, but in exposed positions they are better left for another ten days. In all cases the weak and unripe wood should be cut away, leaving only that which is strong and well matured. Unless it is necessary to increase the size of the plants, strong-growing varieties should be cut back to within five or six eyes of the base, while the weaker-growing kinds may be pruned closer, and always to an eye pointing outward.

The Kitchen Garden.

Tomatoes.—A sowing should be made now to produce plants for cultivation in the open garden. Dickson's Open Air is one of the best for this purpose.

Parsnips.—The roots of last season's crop should be lifted at once and placed in some cool place where a covering of soil or ashes can be applied to keep them in plump condition. The ground ought then to be dug, and, if necessary, a dressing of manure should be given. This ground may afterwards be occupied by late Cauliflower or Broccoli. If not already done, the Parsnips should be sown on ground which has been deeply dug or trenched for the purpose. There should be no delay in sowing the main crop of Onions. Carrots may also be sown now on well-prepared soil, and should be ready for use in June.

Beet.—If a warm south border is available, a sowing of Turnip-rooted Beet may be made now, and again in a fortnight's time. This should be ready for use in June, when young roots will be appreciated.

Peas.—A good sowing of Peas may be made now in the open garden for use about the end of June. As soon as the young plants are through the soil, they may be carefully earthed-up and the stakes placed in position. The Pea has many enemies, which must be carefully guarded against. The Pilot, Early Giant and Gradus may all be sown now.

Carrots in Pits should now be ready to thin. Let this be done before the plants become drawn. Three inches should be allowed between the plants. Water the bed carefully as soon as thinning is finished, to settle the soil about the roots. Give air freely when the weather is favourable. Carrots which have been allowed to remain in the ground through the winter should now be lifted and placed behind a north wall, where a slight covering of soil or ashes should be provided to keep them in good condition.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—Any time after this date the general or main crop of Onions may be sown out of doors; this, of course, will entirely depend on the condition of the soil. If the ground was turned up before the winter, the soil will be well pulverised and in good condition to sow. From this sowing one does not expect to get very large specimens, nor are they desirable for keeping purposes; consequently it will not be necessary to work in any manure at this stage. One should always, however, give the ground a good dressing of soot. This will be found to be a splendid fertiliser, not only to assist growth, but as a preventive against the maggot. As soon as the Onions can be seen in the rows, the Dutch hoe should be kept going to keep down weeds and prevent the soil becoming hard.

Peas.—A sowing of an early variety might be made outside now, and for this select a warm border where the soil is inclined to be light. It is not necessary to have the ground so heavily manured as one would have it for maincrop varieties. As soon as the plants can be seen in the rows, give them a dusting of soot, which will ward off slugs and other pests. One usually finds that it is this early crop that suffers most from vermin.

Round or Summer Spinach.—A sowing of Spinach may also be made now. Do not sow between the rows of Peas, as is so often done. Unless space is very limited, I think this practice is to be condemned. This sowing should be made on a warm border, and, if thinned out, the plants will not be so liable to run to seed. Continue to make a sowing, say, every three weeks, which should give a constant supply.

Parsley.—As a rule, for early supplies of Parsley I prefer to make a sowing in boxes and plant out next month. Where this is not possible, a sowing may be made any time now. We usually grow our Parsley as an edging, and a very handsome edging it makes. Sow the seed sparingly and thin out the seedlings to at least 3 inches apart.

French Beans.—Heated pits or frames are usually fully occupied at this season, but if one can be spared, it will be wise to make a sowing of French Beans in it. This would prove a useful crop to follow plants grown in pots, and so keep up the supply of this fine vegetable.

The Flower Garden.

Pentstemons.—Those growing in frames will now be making growth, and as it is rather too early to transplant them in a sheltered border, I would advise pinching them now. This pinching is usually done after they have been transplanted, but I prefer doing it now, and they make very fine plants if treated in this way. Where one wishes to increase the stock of some good varieties, these tops can be rooted in the propagating-pit, and will make quite good plants by April. Pentstemons are becoming popular for massing in the flower garden, and they are very satisfactory plants for that purpose. They require no staking (always a consideration) and will last in bloom longer than most bedding subjects. The latest addition to this class is Mrs. Fred Fulford, glowing crimson-scarlet, possibly the finest of its colour in cultivation.

Violas that have been rooted in cold frames should now be placed in nursery lines at the foot of a wall or hedge, and so make room for other bedding plants that require to be hardened off.

Crataegus Pyracantha (the Fire Thorn).—For clothing a wall this is a plant that is not so frequently met with as it might be, considering its adaptability. It carries its orange scarlet berries throughout the winter, and these being decidedly bitter, birds seldom trouble it. This is an excellent plant for any wall, thriving equally well on the north and east, and where space is limited it will just suit it, as it fruits more freely when the roots are confined.

Tropæolum speciosum.—This is without doubt one of the prettiest of all climbers, alike for its elegant foliage as for its rich crimson flowers. It is very hard to establish in the warmer counties of the South, but no difficulty should be experienced in getting it established in the North. For some years past I have been successful in growing it on almost any aspect. I prefer to get the roots, or underground growths as they are called, in preference to plants that have started into growth. My practice is to take out a small trench at the foot of a wall or hedge, and into it put some leaf-soil; then lay out the roots horizontally and cover them over with some fine soil. On no account must they be disturbed after they have been planted.

Plants Under Glass.

Poinsettias.—These will now be out of bloom. They ought to be gradually dried off and, finally, water should be entirely withheld. When resting, care must be taken to store them where the temperature will not fall much below 50°. About the end of March or the beginning of April they may be partly cut back and placed in heat to produce cuttings. April or May will in most cases be quite soon enough to begin propagating.

Clivias (Imantophyllums).—These useful greenhouse plants are not now grown as extensively as they used to be, and yet I find they force readily. A few plants put into heat from time to time will produce fine spikes of pale red flowers, which will be much appreciated for decorating. Unlike most plants when forced, the colour seems to me to be intensified.

The Hardy Fruit Garden.

Gooseberries.—As I pointed out some time ago, there is not nearly enough attention paid to the pruning and training of the humble Gooseberry. Anyone seems experienced enough for this work. In many cases, when the pruning has been completed, the bushes resemble as much as possible a hedge that has been indifferently trimmed. Some years ago I was very much struck with a system of training Gooseberries I saw practised in a garden in Kent. Each bush was supported by a stake about four feet in length. To this stake the centre shoot was trained, which gave it the appearance of a pyramid. The wood in every part of the bush was thoroughly ripened, and the crop was one of the finest I have ever seen.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

DECORATIVE varieties are being cultivated more extensively every year because the blooms can be obtained by amateurs from August to Christmas without a great deal of labour and expense. New varieties must be purchased, and no enthusiast will hesitate in this matter; and even where there is a good stock of cuttings on the place itself, wise growers will occasionally renew it, or a part of it, from a fresh source.

Accommodation for Plants.—Now, amateurs, as a body, do not possess unlimited accommodation either in the garden itself or under glass, and, of course, they must grow plants accordingly. Even a dozen will afford many blooms in December and at Christmas-time. By judicious stopping, each specimen may be relied on to yield at least ten flowers, so from twelve plants more than one hundred fine blooms may be available, and as these flowers last fresh for quite a fortnight, a very nice display will be secured at a season when all kinds of flowers are scarce.

Propagate by Cuttings Now.—Those of early, medium and late varieties may be propagated now. Insert them singly in small pots or three in 3-inch ones; then, when rooted, they should be repotted in larger pots without being disturbed. In this way fine pots of plants, bearing at least two dozen blooms, will be available next autumn. Use a very sandy compost, but place a little well-rotted manure in the bottom of each pot before putting in the soil. Make use of a cold frame for striking the cuttings. They may be rooted in a frame on a greenhouse stage; but at this season the cuttings soon droop, on account of the heat and dry atmosphere, unless very carefully attended to. In the cold frame only a light shade will be needed when the sun's rays are strongest. The early varieties may be propagated in boxes instead of flower-pots, inserting them 2 inches apart each way. From the boxes, transplant the rooted cuttings to others a little deeper, and from these, in the early part of May, to their flowering quarters. When the plants are well rooted and about four inches high, stop them by pinching out the point. This operation will induce side shoots to grow, and usually the three top ones are the strongest and take the lead. Well, another stopping means an addition of six shoots, often nine, and so an amateur cultivator can readily see that, when finally disbudded, a dozen blooms at least are ensured. If not disbudded, each pot of plants presents in appearance a huge bouquet. In the matter of stopping, the late-flowering varieties should be dealt with first and the early ones last. Sometimes a natural break near the right time obviates the necessity for stopping.

Good Early Varieties.—Gertie (salmon pink), Hetmine (pure white), Elstob Yellow (better than Horace Martin), Diana (deep bronzy red), Harvest Home (red, tipped gold), La Somme (mauve pink), Normandie (blush pink), Provence (rose pink) and White Pet.

Medium.—White Quintus, Le Pactole (bronzy yellow), La Garonne (terra-cotta), October Gold (old gold), Source d'Or (orange red, tipped gold), Viviani Morel (blush mauve), William Turner (white, makes a fine specimen plant), Crimson Source d'Or, Countess (pure white), Cranford Yellow, Mrs. Luxford (Indian red) and Janet (reddish buff).

Late.—A. J. Balfour and Dr. Enguehard (two good pinks), Baldock's Crimson, December Gold, Mrs. J. Thompson (white), Western King (white), Nagoya (yellow), Embleme Poitevine (yellow) and Tuxedo (reddish bronze). Avon.

NURSERY NOTES.

NEW ROSES IN IRELAND.

IN July last I paid my second visit to the beautiful Emerald Isle, and as I know that so many readers of THE GARDEN are very much interested in all that pertains to our national flower, especially its novelties, I thought a few notes as to what I saw during my visit to the three famous nurseries at Portadown, Belmont and Newtownards would find a welcome in its pages. I have visited most of the leading establishments, both at home and abroad, where Rose hybridising is carried out extensively, but I think I should have to award the

had been budded or would be budded. At one time Mr. McGredy used to bud five or six each of every seedling he raised—a most prodigious undertaking—but now he is obliged to make selections and bud only the most promising. As it was, I saw one breadth of stocks containing some 30,000 that had been budded with selected seedlings, no sort in greater number than ten or twelve. What an interesting plot this will be this summer! Even while I was there, there were very many kinds that had started into growth, and I detected some rare gems, some nearly black, others of most wondrous shades. I have an invitation to go over and see this block in bloom this summer, and I only hope I am able to avail myself of it. Mr. McGredy is working on the right lines. He is providing us with rare colours of splendid vigour of growth.

We who had the handling of many thousands of plants last autumn know only too well of the great popularity of Lady Alice Stanley, Mrs. Wakefield Christie Miller, Mrs. Alfred Tate, Edward Mawley, Mrs. Herbert Stevens, Mrs.

FREESIA EXCELSIOR, A BEAUTIFUL NEW VARIETY SHOWN BY MESSRS. SUTTON AND SONS AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW LAST WEEK. (See page 120.)

palm for this to Messrs. McGredy. No one could view that splendid house, some 90 feet long, full of plants, every one bearing huge seed-pods, without being impressed by the sight. The crosses made all seemed to have been effective, for the plants bore from three to six, and often more, grand hips, many of the size of small Pears. I was informed that Mr. McGredy had long been working with the old Tea-scented Roses. I could hardly name a variety but what he said was in that house to be used as a pollen parent chiefly. Can we not trace, now that we know, the influence of some of these old Tea Roses upon several of Mr. McGredy's seedlings? Surely Mrs. Herbert Stevens, in its almost horizontal and slender growths, has a large infusion of the old Niphetos. Comtesse de Nadaillac, Mme. de Watteville, Devonensis, Souvenir d'Elise Vardon and others were all in some way utilised and blended with the Hybrid Tea.

In another huge structure were to be seen thousands of the little seedlings, many of which

Amy Hammond and others. Next autumn I expect a great demand for Old Gold. It is typical of Mrs. Alfred Tate, only of a very intense old gold colouring. Something like 10,000 of this variety had been budded before my visit, and the same number each of Mrs. Charles E. Pearson, Mrs. Frederick Vanderbilt, Lady Mary Ward and Edith Part. This will give some idea of the estimation in which this year's novelties are valued by their raiser. I saw such a number of good things that I cannot possibly name them all.

One named after Mrs. W. D. Prior will be heard of in the future. It is a beautiful golden sort with very long buds. Duchess of Manchester is a fine Rose of tree flowering habit. I noted that it bore some resemblance in its flower to E. Vevrat Hermanos, that very vigorous but shy blooming climber, and I was informed that this Rose was its pollen parent. Colleen is a "great" Rose. Practically every flower comes perfect, and there is a distinct yellow base to its rich rose coloured

blossoms. The petals of this Rose are enormous. Mrs. C. E. Pearson will probably surpass Lyon Rose, and Lady Mary Ward, Mrs. F. Vanderbilt and Edith Part are all worthy additions. The latter is like a heavily shaded Mme. Abel Chatenay.

A beautiful golden seedling was far better than Mme. Ravary, as seen growing at Portadown, and no small attraction was its beautiful Beetroot-coloured foliage. Here also was a lovely scarlet better than Liberty. Iona Herdmann, Florence Forester, Mrs. Ricardo and Mrs. F. Dennison were all gems that we shall all be wanting when introduced. To view the stupendous number of seedlings, both here at Newtownards and Belmont, one could not help feeling that Rose-lovers are assured of novelties for many years to come. It is to be hoped that the special attention that will be directed to the production of fragrant novelties by the gift of a beautiful challenge cup by Messrs. Clay and Son will induce raisers to strain every effort towards this end. I feel certain that if raisers would refrain for a time from intercrossing so many of the scentless Hybrid Teas, but rather utilise the Damask and Hybrid Perpetuals as pollen parents, at least we should have more fragrant novelties. I fear that this quality enters very little into the estimation of a new Rose on the part of the judges who award the gold medals, but I am also certain that if we could obtain a jury from the general public, this quality would not be ignored.

From Portadown I journeyed to Belmont, and met with a most hearty welcome from Messrs. Hugh Dickson. It is always a pleasure to go to Belmont. Both of the brothers who control this huge business are filled with enthusiasm for the production of novelties of merit. Mr. Hugh Dickson, who carries out the hybridising, sets himself a very high standard, so much so that novelties I thought splendid did not attain to his ideal. This is as it should be, and certainly we are sure of having good introductions from such a source. (In my notes the word "glorified" occurs very frequently.) One is a glorified Mme. Abel Chatenay, another a glorified Mme. Segond Weber, another a glorified Mrs. Foley Hobbs, and so on. Perhaps one of the greatest novelties I saw was Gorgeous. I started putting three crosses to certain kinds, but found very soon I had to increase them to four, and then to six in the case of Gorgeous. There is a blending of amber, crushed Strawberry, with tips of ivory white. Mrs. John Jamieson is a splendidly built Rose; Archie Gray may take the challenge cup, for its scent is delicious; Mrs. R. J. McMordie has huge flowers of a most lovely shade; Mrs. Willie Dickson is the glorified Chatenay; Mrs. Hugh Dickson is one of the "great" Roses, and is it any wonder that every bud was being worked of it? Countess Clanwilliam is considered by the firm as one of the very best productions, and is a glorified Luciole. Duchess of Buccleuch, ivory and cream, tipped pink; Ulster Gem, a splendid addition to single Roses, the first real yellow variety; Mrs. J. W. Parker will completely rival Bessie Brown; and I shall not be surprised to find it at the head of Mr. Mawley's Analysis of show Roses very soon. Charming is well named, and will be a formidable rival to Mrs. A. R. Waddell. Brilliant is also well named; it is of the colour of Pelargonium Paul Crampel, and one can imagine what a bed of this Rose will be like. Muriel Dickson has Pernetiana blood in it; one can see this at a glance. I cannot describe its shade of colour, neither do I think an artist could paint it.

These are but a few of the beautiful novelties in store for us at Belmont. I only wish we did not

need to wait four or five years for some of them; but when a new Rose is produced it takes quite a long time to raise up a stock equal to the demand. I certainly think something should be done to secure to our raisers a sort of copyright in their productions; but how it is to be done has hitherto baffled all who have tried to solve the difficulty. We heard from the Rev. J. H. Pemberton at the National Rose Society's annual meeting that the raising of new Roses did not pay, and I believe the large raiser would endorse this statement. The public should, therefore, if they wish for good novelties, do all in their power to support the industry. I must defer giving an account of my visit to Newtownards for another article. DANECROFT.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowerin9 shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

INJURY TO VIOLETS (Trent).—The fungus Botrytis cinerea is attacking the foliage of the Violets sent. It is one likely to be troublesome if the plants are at all close, and even when they grow vigorously they are apt to become victims of this fungus attack unless every precaution is taken to maintain a free circulation of air around and between the plants.

MAKING A WALL GARDEN (Yorks).—We are obliged by your letter. The whole question of a "few inches" or a "few feet" of concrete or stone resolves itself into one of circumstance, and frequently, as we know full well, stone is scarce, while suitable material for concrete is more generally available. A wall 20 feet high constructed of a "few feet" thick of rock with a good batter should be as solid as the rock itself. In some localities, however, the cost of so much stone would be prohibitive. Wall gardening presents so many phases that we hope in the near future to deal with it in a short series of articles, and to show by illustration and text what is possible in varying circumstances.

PLANTS TO SUCCEED DELPHINIUM (E. H. S. E.).—The Aconitum would certainly be good as a succession, but it comes late and is tall growing. A much better way of filling the gap would be by planting indiscriminately clumps of the pure white Madonna Lily, which flower in mid-July at 3 feet or 4 feet high, to be followed some weeks later by the spreading plants of Aster Amellus, which take up so little room at other seasons. The Aster is about two feet high, the colour violet or some shade of purple. It is a good plant and a wonderful bloomer. Aster diffusus horizontalis and A. ericoides Desire, reddish and white respectively, would be equally good and free-flowering. These latter are about three feet in height.

FLOWERS FOR CUTTING (Nemo).—In the 4-foot-wide bed at the house end of the lawn you could not do better than plant Sweet Peas, which are both useful for cutting and profuse in flowering. Of these you might plant circular groups, as shown in a recent issue of THE GARDEN, selecting the colours to your liking. With these might be interspersed the pink Ivy-leaved Pelargonium Mme. Crousse and white Marguerite Mrs. F. Sander, and with a margin of Godetia a gay border would result for a long time. For the narrower side borders you might have Cornflowers, Sweet Sultans, Gaillardias, Stocks, China Asters in variety and Carnations. In the 11-foot-long bed, Heliotrope pegged down, with a margin of white Alyssum, would do quite well, and in that at the back Iris pallida, I. Mme. Chereau, I. Mrs. C. Darwin, Montbretias, Phlox Mrs. Jenkins, Gaillardias, Columbinas, Aster Amellus, A. ericoides Desire, A. cordifolius, A. Beauty of Colwall, Rudbeckia Newmanii, Trollius Orange Globe, Helonium pumilum, and single and double flowered Pyrethrums. These latter are perennial, and well suited to your requirements.

BORDERS FOR PERENNIALS (Bullion).—It is not quite clear from your letter whether you require perennials for the whole of the borders around the lawn. We note you have Apple trees apparently in the centre of the north border and Poplars—these presumably near the wall on the south side. Not many plants would succeed near these latter. Other drawbacks to success, if we rightly interpret your figures, are the 20-foot-high walls at east and west, though this might not be serious if, in planting, you keep the subjects 2 feet or 3 feet from the walls. For the east end border you might arrange Hollyhocks, Delphiniums in variety, Sunflowers, tall Michaelmas Daisies, white and rose perennial Pea, Helonium Riverton Beauty and other such plants in the back row, setting out three or more of each to form effective groups. In the next line, which should be at least 2 feet from the first, arrange Anemone japonica, A. j. alba, A. j. rosea, Phloxes Mrs. E. H. Jenkins, Iris, Coquelicot, Countess of Ilchester, Lady Mary Hope, Regulus, Selma and Queen Alexandra, together with Iris pallida dalmatica, I. Mme. Chereau, I. Dr. Bernice, I. Darius and I. Mrs. C. Darwin. These may be alternated the one with the other, and by introducing Lilium croceum, L. candidum, L. speciosum and others among them obtain greater variety. In the front line, single and double Pyrethrums, Aster Amellus, A. acris, Helonium pumilum, Trollius Orange Globe, Iris Victoriae, Phlox Tapis Blanc, Campanula carpatica alba, C. Moerheimii, C. glomerata speciosa and Clove Carnations might appear; while, if room still remained at the margin, Pinks, dwarf Campanulas, Aubrietias and Mossy Saxifrages should be planted. The dry raised border at the opposite end, if deeply trenched and heavily manured, would grow Irises of several sections quite well, or you might make it gay with Carnations, Snapdragon, Pentstemons and other plants in variety. The Spanish Irises would prove most useful in such a case.

ROSE GARDEN.

ROOTED BRIAR CUTTINGS (D. D. F., Kelso).—We fear you will have some difficulty in purchasing these, as Rose-growers, as a rule, do not grow them for sale. Try your local Rose-grower, or, perhaps, Messrs. Cocker and Sons, Aberdeen.

ROSE CLIMBING MME. MELANIE SOUPERT (Annie Laurie).—We think any of the nurserymen who advertise Roses in our columns could supply you with this, even if they do not list it. If not, and you will send your full name and address, we will communicate with you by post.

CLIMBING ROSES IN GREENHOUSE (Westbank).—The side shoots, or laterals, of Climbing Caroline Testout and Climbing Liberty should be cut back hard at once, say, to one or two eyes each. If the plants were pot-grown, they should flower well; but if they were from the open ground and planted in the border last October, you must not expect much bloom this season.

REARRANGING A ROSE GARDEN (C. E.).—We have much pleasure in advising you upon rearranging your Rose garden, and as it is impossible to deal fully with it in THE GARDEN, we have forwarded a sketch by post, indicating therein the proposed alterations. We quite agree with you as to the spotty effect as at present arranged, and we have noticed many gardens sadly marred by this apparent careless grouping of colours. You must discard entirely Reine Marie Henriette, as it is too vigorous for bedding. W. A. Richardson is hardly the kind for your purpose, as its growth would not harmonise with the other beds unless you peg it down. We have suggested the best kinds, according to your wishes. Should you wish to keep one variety to a bed, you would, of course, use that variety you now possess.

PRUNING CONRAD F. MEYER (Howden).—When this grand Rose is grown in clumps, much of its beauty is lost if allowed to grow away as a free bush. If only one plant in a clump, the variety might very well be allowed to grow almost naturally, as in time its growth would arch over like a wild Rose of the hedgerows. In your case we would advise cutting out some of the oldest wood quite close to the ground, and the ripened young growths retain some 3 feet long, others 4 feet, and one or two 5 feet. Do not encourage too dense a growth. If the plants are fairly close in the bed, you could retain about four growths per plant; the blooms would be all the finer for this thinning. Be sure to feed the plants well, and, if you do this, you will obtain splendid blooms almost exhibition size. A clump or two of the white sport, Nova Zembla, would be a welcome addition, as its snow white, fragrant blooms are always welcome.

THE GARDEN.

No. 2208.—VOL. LXXVIII.

MARCH 14, 1914.

NOTES OF THE WEEK.

Writing for Catalogues.—It has come to our knowledge that a good many people, when writing seed or plant catalogues, place their letters in unsealed envelopes and stamp these with only a halfpenny stamp. Under the Post Office Regulations this is not permissible, and letters sent that way are surcharged one penny on delivery. It is a serious item to nurserymen and seedsmen, and those who apply for catalogues should either use post-cards or penny stamps.

A Beautiful Early Flowering Shrub.—Although *Protea persica* was introduced into this country as far back as 1848, it is seldom found in gardens. It is a very attractive plant in February, when whole branches are often properly furnished with flowers, the crimson-tipped stamens of the male blossoms being singularly beautiful and uncommon. Though perfectly hardy, it benefits if sheltered from the cold winds by other trees. Apart from its attraction at the season of the year, it is one of the most handsome of foliage plants during the autumn.

Small Daffodils for the Rockery.—Both *Narcissus minimus* and *N. lobularis* are excellent subjects for the rock garden. They flower early in the year, and when bright colour is wanted, neither of them is fastidious about soil, provided that it is light and well drained. *N. minimus* is the smallest Daffodil there is, and one of the first to flower. In the Midlands it can be seen to bloom this year about the middle of February in sheltered places, while in the South of England it is considerably earlier. *N. lobularis* follows it with about ten days' interval. It is quite twice the size of *N. minimus*, and is of such a self colour, the perianth being a much deeper yellow than its trumpet. When once established, both will take care of themselves.

Pruning Ivy.—Few plants are so generally noticeable as varieties of Ivy, either for clothing a wall, hiding unsightly objects, or for covering the places under trees. Ivies may be planted in pots, and if established plants in pots can be used, so much the better, as they go straight to work without any check. There are a number of beautiful varieties to select from, and although the large-leaved Ivies grow quickly, the smaller-leaved varieties are preferred for most purposes. To keep Ivy bright, it should be cut over once a

year to remove the old leaves. This is best done now, for although Ivy can be cut at almost any time during the winter, by leaving it until now it soon becomes furnished with its new leaves, and therefore does not remain bare for long.

A Giant Groundsel.—Few plants can be more effective at the present time than *Senecio grandiflorus*, with its large, handsome leafage and noble stature, the growth of which sometimes reaches to a height of 10 feet and terminates with a huge, flat corymb of yellow flowers from 1 foot to 2 feet across. The species is a native of Mexico, and, to secure good specimens for the coming season, seeds should be sown at once. It is a very striking plant for the subtropical garden, and if

TRITELEIA OR BRODIEA UNIFLORA, ONE OF THE EARLIEST BULBS TO FLOWER IN SPRING.

the flowering period is not reached in the open, the plant may be lifted and potted for decorating the conservatory in the winter.

A Beautiful Camellia.—Anyone who is familiar with the large plant of this Chinese species growing in the Temperate House at Kew cannot fail to have been impressed by its magnificent flowers when at their best during February or early March, for they are quite distinct from, and appeal to the decorator more than, the formal flowers of many of the varieties of *C. japonica*. The bright red flowers are semi-double, with large, irregular-shaped petals and a central mass of golden stamens, individual blossoms being from 5 inches to 6 inches across, with a resemblance to those of a semi-double *Pæony*.

The Spring Starflower (*Triteleia uniflora*).—This beautiful bulbous plant, native of Buenos Aires, is now flowering in many gardens throughout this country. At Wisley it has made a bright display for the past week or two, where it rejoices in a sandy soil and sunny position. The flowers are about six inches high and pale lilac in colour. Like many other garden plants, the Spring Starflower has the misfortune to bear a number of scientific names, having been placed in three genera, viz., *Triteleia*, *Brodiaea* and *Milla*.

An Early Daffodil.—The earliest of the large-flowered Daffodils to open with us outdoors this year was *Narcissus pallidus præcox*, the first blooms unfolding on Friday, the 6th inst. This is a very dainty Daffodil, and one that ought to be more extensively cultivated. Unfortunately, it has the undesirable trait of dying out in many places, and fresh bulbs have to be planted every two or three years. But for its earliness alone it is well worth the expense and trouble, and in a few gardens it thrives and increases. We have it nestling under the wall of the house, by the front door, the aspect being due south. These early spring flowers seem to appreciate close association with the dwelling-house, though, a grass-carpeted copse would provide a more natural setting.

Coloured Freesias.—We lately saw a good pot of *Le Phare*, which is one of the brightest of the new coloured race that have been sent out in recent years by the firm of Van Tubergen, jun., of Haarlem. It is of a deep rose colour, the individual blooms on the small side, but to make up for this deficiency it is a very free bloomer and deliciously scented. The price of this and all the others is high, but we are told by those who have grown them that they are just as easy to manage as either *F. refracta alba* or *Leichtlini*. There is no difficulty in working up a little stock, if the bulbs are looked after when they have done flowering. They want feeding with some fertiliser until the leaves begin to turn yellow, when water must be gradually withheld and the bulbs thoroughly ripened by the pots being turned on their sides and put in a warm, sunny place out of the reach of wet, until they are shaken out and graded at planting-time in August.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Hardiness of *Spiræa lindleyana*.—In a recent issue I saw it stated that *Spiræa lindleyana* can be only "recommended with safety for Southern gardens." I have a very fine specimen, of which I enclose a photograph, in my Yorkshire garden, 500 feet above the sea-level, on the north side of my house. The photograph was taken on August 26. The largest stump measured 16 inches in circumference, and the largest living branch 12 inches. This shrub was an offset from a plant growing in a small garden in Richmond, Yorks, which was given me quite forty years ago. I have been told since that it was not known in England so long ago. My impression is that it was sent to my friend from South America. I have given away many offsets of this Yorkshire

Sherborne House, Northleach, R.S.O. [We thank Lord Sherborne for his interesting letter, and should be pleased to hear from any other readers who have found this charming little Heath thrive in limestone soil.—ED.]

Saxifraga burseriana and Its Varieties.—In your issue of last week "Alpinist" states on page 114 that he doubts if *Saxifraga burseriana* and its varieties *Gloria* and *major* can be distinguished when grown under similar conditions. My little experience with them has shown *S. b. Gloria* to be totally distinct from the type; indeed, for gardening purposes it might even be a distinct species. I have one clump of the type and one of *S. b. Gloria* growing side by side in the same pocket of my rock garden. Each clump measures about eight inches in diameter. On February 13 the type began to open its beautiful snow white flowers, fifteen in all. *S. b. Gloria* did not begin to flower until February 24, just as the type was going over. No fewer than thirty-seven strong

how such a specimen was obtained. I would dispel any doubts upon the quantity of flowers the plant carried. The plant was shown in an 8-inch pan, 6 inches deep, with 354 perfectly developed flowers. There were other inferior buds setting in the crowns of the plants which were not in flower at the time of exhibiting, making a total of about three hundred and seventy. These later buds have come into flower since; the majority of the 350 have gone over or faded. I counted the flowers before exhibiting, and had two witnesses to observe that the number was correct. The method of cultivation is simple. The pans are well drained with potsherds and red brick, broken up. A layer of turfy material is placed over the crocks, and sandstone 2 inches thick and 4 inches deep is set upon the turfy material and allowed to keep above the soil, which should be pressed firmly between the sandstone when potting or placing them in the pans from pots or division. The soil consists of a small quantity of loam, and this binds the compost together as it is mounded above the level of the rim of the pan. A slightly larger quantity of finely sifted leaf-soil than the loam is added, with, also, coarse sand, sifted coke-ashes and old mortar rubble. These ingredients are well mixed together. A very important matter is the site for *S. burseriana* and its allies. Our method is to plunge them in a bed of coke-ashes after they have done flowering, and start them into growth in early May, out in the open in the brightest light possible, keeping them well watered through the summer months. In October the plants are transferred to cold frames and plunged in ashes, with air admitted continuously night and day. The plants are never shaded, either while in flower or out, not even if division has taken place. This type of *Saxifraga* must not suffer from drought at any time, and while in bud search must be made for green fly in the axils of the crowns of the plants, for the insects transport themselves to the flowers, which will not open if infested. We pick them out with small tweezers in the early stage if a plant contains the pest.—M. E. MILLS, *The Gardens, Coombe House, Croydon, Surrey.*

Peat Moss Manure for Rhododendrons.—I am reading the symposium appearing in THE GARDEN upon the subject of peat moss manure with interest, especially as I am making a bed for Rhododendrons and thought of using it. One of the contributors spoke of having used it for that class of plant, so I wrote him for further information, and received the enclosed reply, which perhaps may prove of interest to readers of THE GARDEN. ["I have generally used it with about one-fourth of its own bulk of sea-sand, of which we can easily get an abundance, being on the shore of the Firth of Forth. I have, however, used it with good effect neat, and always almost fresh from the stables. I have been particularly struck in one instance as to its utility in the latter form. When I took charge of the gardens here, thirty-two years ago, I found what was evidently from its foliage (there was no flower) a good variety of a hybrid Rhododendron in the last stages of decay, under a thicket of trees. I had it removed to an open situation, where I planted it with an abundance of pure moss litter fresh from the stables; it gradually began to resuscitate, and for many years it has been an object of great beauty (its quality being all I had anticipated), and at the present time it is smothered with swelling flower-buds. I have no doubt you would find it equally useful mixed with good fibrous loam.—CHAS. COMFORT."].—HUBERT BENSTED.

A FINE PLANT OF SPIRÆA LINDLEYANA IN A YORKSHIRE GARDEN. THIS SHRUB IS GENERALLY CONSIDERED HARDY ONLY IN SOUTHERN COUNTIES.

specimen, and have now a good plant in my garden in Bucks.—HEDGERLEY.

—The note by Mr. Loudon of South Woodford in February 28 issue, page 102, was of interest to me. We have three plants of the same shrub here. They are on heavy soil and absolutely exposed to the north, yet they flower in profusion, and have been greatly admired. At present they are again very promising.—J. F. ROUGHT, *Buckland, Berks.*

Erica carnea in Limestone Soil.—Surely the little pink Heath which is now flowering so abundantly here is *Erica carnea*? Yet I see that a writer in your issue of February 28, page 102, says that *E. carnea* "spreads rapidly in a sandy peat soil, or it may readily be grown in a loamy soil if there is no lime present." The garden here is situated in the middle of the Cotswolds, and the soil is nothing but a limestone soil, yet *Erica carnea* spreads rapidly and flowers abundantly, and I have always looked upon it as the one Heath which would flourish on limestone.—SHERBORNE.

flower-stems were produced, each bearing a magnificent flower fully twice the size of the type. The entire plant seems smothered with blossom still. The petals appear to be of stronger texture than in the type, and as the flower-stalks are quite 2 inches long, they are not so easily soiled. As they come into bloom I protect them with a pane of glass overhead, and also have to surround them with a perforated zinc ring to keep slugs from eating the flowers. My plants are growing in very gritty loam facing south-east, but receive a little shade from the east from a plant of *Hypericum olympicum* in an adjoining pocket. They are watered copiously in dry, hot weather, and seem to thrive well under these conditions.—NORMAN G. HADDEN, *St. Audreys, Malvern.*

—Reference has been made by "Alpinist" in your issue of March 7 to the *Saxifraga burseriana grandiflora* exhibited by Mr. Frank Lloyd of Croydon and illustrated on page 116 of that issue. The writer stated that it would be interesting to hear what the cultivator had to say upon

Peat Moss Litter Manure : Is it Injurious ?—I have used a great deal of peat moss litter manure, and have a high opinion of its manurial qualities. I find it especially good for digging into flower beds and borders, where it would not be wise to use strong farmyard manure, which would cause the plants to make foliage at the expense of flowers. Where one has difficulty in growing carrots, it may be applied as a top-dressing just after they have been thinned. This will prevent an attack of Carrot fly, for it is well known that any evil-smelling substance is repugnant to this pest. As a top-dressing to inside Vine borders it is invaluable, as it tends to keep the roots near the surface, a point always to be aimed at. On the whole, however, I consider that for general purposes it is not superior to well-made farmyard manure; nevertheless, I consider it an excellent substitute.—JOHN HIGHGATE, *Hopetoun Gardens, South Queensferry, N.B.*

— I have not had much experience with peat moss litter, for the reason that I would not have it in the garden. I do not think this is altogether prejudice, for what little I have had dug into the ground never appeared to me to incorporate itself with the soil, but would turn up again at a later digging without, apparently, having imparted much virtue to the soil. In my opinion, straw manure, well rotted, is infinitely superior as a manure.—ARTHUR CULLOCK, *The Gardens, Copped Hall, Epping.*

— My experience with this manure has been far from satisfactory. Some years since I used it in a trench for growing Leeks. The manure was rather fresh. Possibly a month had elapsed from the time of planting before any bad result was noticed. Then gradually the young plants died off. The shortage of good stable manure is a serious drawback in many gardens. When purchasing manure, one has to be very careful, and the loads as they arrive should be examined. Savings from joiners' shops, and even sawdust, are used in many stables as bedding, and, needless to say, the manure from these materials is injurious to plant-life. Sweepings from the streets are so dangerous, that is, from streets where preparations containing tar or other poisonous substances are used upon the surface. I notice in a recent issue of a contemporary that Mr. W. Crump, the well-known gardener at Madresfield Court, writes: "Do not use fresh manure, especially if the animals have been littered with peat moss."—C. R.

Hardy Cyclamen.—These flower both in winter and early autumn, though perhaps the winter-flowering kinds, veritable harbingers of spring, they undoubtedly are, receive the greater welcome because of that fact. This year, chiefly because of the exceeding mildness of the season, they are earlier than usual, as witness the fine displays that were forthcoming at both the January meetings of the Royal Horticultural Society. These, doubtless, had received frame protection—they certainly afforded no proof of having been rewarded in heat—though, even so, their flowering was abnormally early. Thus grown they make lovely pictures in the alpine-house, and even though quite miniature as compared with the plants of the Persian race, they are none the less welcome, certainly none the less beautiful or charming. Not less pretty—decidedly more natural—are they when seen carpeting the ground in sheltered woodland places, where, nestling in the scant grass or herbage of the time in sweet communion with all around, they brave the

hardships of the weather, and, protected by their carpeting leaves, remain fresh and bright for many days.—E. H. J.

The Yellow Snowdrops.—The Snowdrops with yellow instead of green markings are in full bloom at present, and are much more charming than many who consider such flowers as freaks would suppose. I have the single lutescens and flavescens, with the double one, and one or two others. They are very beautiful, although this is not said in any mood of depreciation of the common Snowdrop with its exquisite green markings.—S. ARNOTT.

Rhododendron moupinense.—The illustration of this Rhododendron in THE GARDEN for February 21, page 98, gives an excellent idea of an attractive little plant which, when available, will be a welcome addition to the small-leaved, dwarf Rhododendrons suitable for the rock garden. The plant shown at Vincent Square was raised at Warley from seed sent from Western China by Mr. E. H. Wilson when collecting for the Arnold Arboretum. It flowers the third year from seed, and has proved itself to be perfectly hardy during its five years' experience in the open at Warley.—E. WILLMOTT.

Sowing Hollyhock Seed.—In reference to your note upon this subject on page 89, February 21 issue, it may interest your readers to know that the noted growers, Messrs. James Vert and Sons of Saffron Walden, Essex, raise very large quantities of plants annually from seed sown in the open ground in May. Plants raised at this time become strong and sturdy enough to stand throughout the winter. To this firm, who have made a careful study of the Hollyhock for many years, we are indebted for the introduction of many beautiful varieties, and their annual exhibits at the Royal Horticultural Hall, and also at Shrewsbury, are always a source of pleasure to florists. In order to check the spread of disease, which is such a serious drawback to the cultivation of these noble plants, the above firm have prepared a specific, in powder form, which has proved a boon to growers.—COLIN RUSE, *Folly Farm Gardens, Sulhamstead, near Reading.*

The Hailshamerry.—A paragraph in THE GARDEN for February 28 on autumn-fruiting Raspberries reminds me that I have never publicly acknowledged, as I intended to do, my deep debt of gratitude to the Hailshamerry for having supplied me with fruit for delicious little pies or tarts last year right on from September to early December. These, by the way, were always made *à la* the small pork or veal pies that one gets at the refreshment rooms of our railway stations. Made in this way, I always think the flavour is better than when the fruit is put into an ordinary dish and cooked in the usual way. The aroma when the crust is broken down is a veritable appetiser for the delicious mouthful that will follow. To start with I had only four or five plants, which in the course of two years have become joined into a line at the foot of a south wall. I cut out all the old wood and prune any shoots likely to bloom before the autumn. Nature does the rest. The berries are acid in flavour, and I find birds leave them severely alone. In appearance they are like fat Raspberries, and the fruits, once formed, go on ripening in most unpropitious weather. I cannot say that the plant is *very* free-fruiting, but there is not much to complain about, and very likely with better treatment than I have given it this might be entirely overcome. I always say that if for any reason I only grew one kind of fruit in my garden, that fruit would be the Rasp-

berry. In jam and jelly, in sauce and salad (alone, with a suspicion of maraschino), in plantation and pie, it is unsurpassed. My grateful respects to the Hailshamerry for the long-drawn-out season that it gives us.—JOSEPH JACOB.

Two Fine Dwarf Lobelias.—Although formal bedding is not now much favoured, there is still room in most flower gardens for a really good Lobelia. For the last seven or eight years I have grown Waverley Blue, and nowhere have I seen anything finer. It is a true blue in shade, the blooms being large and very freely produced. As a bedder it leaves little to be desired, and for pot work far surpasses anything I have ever tried. Under glass, of course, it is a little paler in colour; but it blooms for four or five months on end, and never gets straggly. This variety also keeps well during the winter under ordinary treatment. The other variety I favour is named Halley's Blue; it is several shades darker than the first named, and has a very slight tinge of purple. It is later in blooming, too, than Waverley Blue, but continues right on till frost cuts it down. It is dwarf and very floriferous, but not very good under glass.—C. BLAIR, *Preston House Gardens, Linlithgow.*

MY GARDEN BEAUTIFUL.

I know a garden beautiful,
All filled with rare delight;
No fairer feast of bud and bloom
Sure ever met the sight;
And when a myriad smiling lips
Receive the sunbeams' kiss,
A song of such sweet rapture floats
And trembles into bliss.

Far from the World's unresting ways
My footsteps love to stray,
Unto this garden of delight
Where cooling fountains play;
To rest my tired heart, and feel
Sweet wooing whispers bless,—
The tender eloquence of winds
That sigh their soft caress.

Adown each fragrant winding path
Ah me, what healing blows!
What peace outbreathes from shapely forms
Where Love has lent repose;
The vision of all tints—how fair!
How fair each shining cup!
Dew-filled with glint of diamond,
Where thirsty bird may sup.

And in this paradise of flowers,
The warbling never dies!
It wakes the morn, it lulls at eve,
It closes beauty's eyes;
And as I seek it ever here,
The bloom Heartsease is found;
And so my Garden Beautiful
To me is holy ground.

FRANCES HANDLEY.

FORTHCOMING EVENTS.

March 17.—Broughty Ferry Horticultural Association's Meeting.

March 18.—Stevenage and District Horticultural Society's Spring Show.

March 19.—Linnean Society's Meeting. Royal Society of Arts Meeting: Paper by Mrs. Villiers-Stuart on "Indian Water Gardens." Exhibition of Spring Flowers at Brighton.

PERENNIALS FOR SPRING PLANTING.

It is generally conceded, I think, that for the vast majority of herbaceous perennials and the greatest variety of soils there is no season of the year more suitable for planting than that of early spring. It is as true of the seedling as it is of the more established example, and equally so of that older type of the last named, for which division of the rootstock in conjunction with transplanting are essential if the plant is to give of its best. It is true, too, from the propagator's point of view, inasmuch as it is at that season of the year that the majority of herbaceous perennials, starting root and branch anew, also develop, if opportunity is afforded for so doing, a proportionate number of the latent eyes or buds which may be found about the bases of the stems, it may be of Torch Lily, Tufted Pansy, Delphinium, Michaelmas Daisy, Pyrethrum or many another besides. Left to themselves in undivided clumps, these same buds are either crowded out of existence altogether or go to swell that little forest of weakly growths more common, happily, in clumps of herbaceous border plants a decade or two ago than they are to-day. Thus it would appear that cultivators generally are moving in a right direction, and that amateurs, realising how to make the most of things, are also prepared to cultivate their border flowers on more rational lines than hitherto. In former times it was no uncommon thing to see great mat-like swards of the Michaelmas Daisy occupying a border, the nearly bare stems and inadequate floral display but the net result of starvation—the exacting toll of neglect. To-day we know that these same plants merit annual or biennial division and transplanting, giving, some thirty, some fifty, some a hundred fold of their flowers, as the result of the cultivation bestowed. In principle the same is true of other plants—Phlox, Sunflower, Helenium, Campanula, Day Lily and the like—and the measure of their success at flowering-time will be also that of the cultivation—or lack of it—they receive; hence the desire for timely action.

Preparing the Border.—At all times a well-prepared border is essential to success. Such preparation is more easy of accomplishment in the case of a new border where trenching and manuring can be done in advance, and without such hindrance or interruption as is inseparable from a border not destined for complete overhauling. So much, however, might be advanced in favour of the latter, and so good the results, that in all cases where possible it is worth pursuing. All the same, there are many things—Phlox, Pyrethrum, Potentilla, Japanese Anemone, Delphinium, Day Lily and Pæony, to name but a

few—that are infinitely better if left for two, three, or even a greater number of years, and to these the importance of a well-prepared border at the outset cannot well be overestimated. In the case of heavy soils, the addition of grit and leaf-soil will assist drainage, just as a free addition of lime will assist porosity and do other important work. For light soils the manure should be introduced low down, where later it may play the part of a cool retreat—a sponge—for the roots in the event of dry weather.

The Big Clump Fallacy.—Elsewhere I have written of the “Fallacy of the big clump,” and it is worth repeating here. In short, the big clump of Pæony, Michaelmas Daisy, Lenten or Christmas Rose, Iris, Pyrethrum, or what you

forks are infinitely more safe, in that either can be directed to any point of the plant's anatomy at the will of the operator. In this way solid clumps—Trollius or Pyrethrum—first bereft of soil by washing or otherwise, can be reduced to quite small divisions with impunity. So, too, can larger-growing subjects, as Iris lœvigata and others. In the case of Flag Irises, all that the planter has need of is the most recently formed rhizome with its growing crown attached. The Michaelmas Daisies of the Novi-Belgii set separate readily with the hand, while those of the Novæ-Angliæ group, being more woody, are best wrenched asunder by means of hand-forks. On the other hand, the closer-growing rootstocks of such as ericoides and cordifolius submit to careful division with a knife, and many other instances might be given. The whole object of division is reinvigoration, and the most youthful pieces—the fittest—are all the gardener need bother about, planting these with a free hand in groups to give immediate effect.

Some Useful Plants for Cutting.—There is ever a demand for flowers in the cut state, and the following is a selection: Single Pyrethrums Hamlet (pink) and James Kelway (crimson); double, Ne Plus Ultra (pale pink), Aphrodite (white) and Pericles (yellow); Asters Amellus, ericoides Desire, cordifolius in variety and Beauty of Colwall; Irises pallida, aurea, Mrs. Darwin and Dr. Bernice; Galegas in white and mauve, white Everlasting Pea, Gaillardias, double and single flowered Gypsophila paniculata, Aquilegia chrysantha, Alstroemeria aurantiaca, Campanula persicifolia in variety, Montbretias, Scabiosa caucasica, Lupines, Rudbeckias and Heleniums. E. H. JENKINS.

VIOLETTAS. (MINIATURE-FLOWERED VIOLAS.)

It is many years since the late Dr. Charles Stuart, M.D., of Chirnside, Berwickshire, succeeded in raising the first of this beautiful race of hardy plants. From quite reliable information it appears that this enthusiastic botanist and florist began his original work so early as

the year 1874. In that year he took pollen from a garden Pansy named Blue King, a well-known bedding variety at that period, and applied it to the pistil of Viola cornuta, a Pyrenean species. The cross was quite successful, and in due course a podful of seed subsequently produced twelve plants. When these plants came into flower, they were all blue in colour; but, what was most important, each plant had a good tufted habit. Subsequently, in later years, the flowers of the first cross were fertilised with pollen from a pink garden Pansy, and a measure of success attended this effort. The resulting seedlings gave flowers of more variety in colour and still the same very desirable tufted habit of growth, showing clearly the

A WELL-GROWN PLANT OF LUPINUS POLYPHYLLUS, A USEFUL PERENNIAL FOR CUTTING.

will, is to the planter a delusion and a snare; a youthful specimen is capable of much better work. The obvious reason of this is that the youthful plant has unlimited opportunities for development, while the big clump, with its score or so of crowns, can only develop a tithe of them and root fibres *pro rata*; hence the fallacy.

The Spade-Divided Clump is almost as bad as the last; plays “second fiddle” to it, in fact, in that it retains the feeble crowns of the plant, which, together with the woody portion inseparable therefrom, would be doing greater service for the garden by creating potash *à la bonfire*. Moreover, the spade as a tool for dividing plants is a cumbrous, oftentimes a dangerous thing. A strong pruning-knife or a couple of hand-

influence of *V. cornuta*. These plants were propagated and sent to the Royal Horticultural Society's Gardens at Chiswick for trial, where they gained no fewer than six first-class certificates at the hands of the floral committee, who recognised in the growth of these plants something entirely different from all that other growers had sent in for trial. At a later period Dr. Stuart, when looking through his seed-beds one day, espied what he had long been looking for, viz., a flower without rays in the centre, which was a pure white rayless self. This was in the year 1887—Queen Victoria's Jubilee. The plant was forthwith pulled to pieces, and, in the words of the raiser, "every bit propagated." A notable fact recorded at that period was that the blossoms were beautifully fragrant, and this is not the least of the attractive characteristics of these plants. The foregoing is a true history of the Violettas, the original of which was a more or less chance seedling, the result of a series of crosses that it is impossible to very definitely trace. There are persons who are disposed to question the origin of this charming type of these beautiful hardy flowers, in which attention is called to the fact that the original cross was made in 1874, and that "Violetta" did not appear until 1887—thirteen years after. Lovers of the hardy flower garden will always be indebted to the late

Dr. Stuart for what he did for the Violas and many other beautiful plants, such as the Polyanthuses and the Aquilegias. Between the year of the introduction of Violetta and the seasons of 1896 and 1897 Dr. Stuart raised several very beautiful additions to this new type, few of which, unfortunately, are to be found in the lists of the Viola specialists of to-day. The reason for this, I am disposed to believe, is largely due to the fact that comparatively few growers were prepared to give them their proper place in the garden. They could hardly be regarded as rivals to the large-flowered Violas that are now so extensively grown in all hardy flower gardens worthy of the name. A few sorts like the original variety are vigorous and spreading in their character of growth, and free-flowering withal. The majority, however, are less robust, yet sufficiently hardy to justify a position less trying than an ordinary open border or bed in exposed positions. A much better position for them was found in the rock garden, where slightly sheltered quarters could be afforded the plants during the heat of the midday sun in the

A YOUNG SEEDLING VIOLETTA OR MINIATURE PANSY.

height of the summer. Here they were found to luxuriate, making these quarters bright and beautiful with a profuse display, when so many other occupants of the rock garden had lost their beauty and interest. These plants usually come into flower in April, and continue to blossom quite freely until the early autumn. One of our greatest authorities on hardy flowers, to whom

I submitted a number of my newer seedling Violettas last season, proposes to call these miniature-flowered Violas "Fairy Pansies," a very charming description of these dainty little flowers. He is of the opinion that the plants want cool soil and situations, and would probably thrive on the new moraines which people are making for all the smaller alpine flowers. I am of the same opinion, although my plants are flowered in ordinary nursery beds exposed to the sun's influence from early morning until sunset. Positions that suit the beautiful Grecian Violet (*Viola gracilis*) will answer the needs of the Violettas admirably. I have seen this attractive Grecian species growing in wonderfully vigorous fashion in a small moraine, the moraine soil consisting of the free use of sandstone chips and good, open soil. Such quarters should be ideal for the Violettas. The latter should be planted in small colonies, in order to obtain quick results. The plants are always rather small when distributed, but they very soon make beautiful little tufts 6 inches to a foot in diameter, which are freely studded with dainty little rayless blossoms.

The Viola Conference of 1894 laid down rules to define the ideal properties of the miniature-flowered type, which, briefly, are as follow:

Form may be narrow and more oval, the petals smooth and of good substance. The colour should be bright, clear and striking. The eye should be bright gold or orange, and may run into the under petal, and the flowers must be rayless. The flowers should be sweet-scented. As regards size, $1\frac{1}{2}$ inches in diameter is considered the maximum; and in regard to habit of growth, the plants should be dwarf and procumbent, short-jointed and bushy, and flower-stalks of such length as will bring the flowers well together.

Since the foregoing properties were defined, there have been developments with these plants, and the newer introductions are varied in several particulars, but not in any way to the detriment of the type; rather the reverse.

A few sorts worthy of special mention are the following: Eileen, mauve blue, very free and reliable; Cynthia, pale blush lilac; Sweetness, blush white; Vestal, white; Rock Lemon, primrose; Rock Yellow, bright yellow, richer lower petal; Rock Orange, orange yellow; Estelle, minute white, flushed yellow; Diana, primrose; Rock Blue, deep mauve blue; Molly,

ANOTHER SEEDLING VIOLETTA AT A LATER STAGE. NOTE ITS COMPACT HABIT AND STURDY FLOWERS

rich yellow, ideal form; Grace, white; Queenie, blush; Dainty, pale mauve blue; Ina, deep mauve blue; Lavinia, blush lavender; Butterfly, lower petals rich yellow, upper petals pale yellow; and the type. There are many other good things of which little is yet known, but the aforementioned varieties should make a most interesting collection.

Highgate, N.

D. B. CRANE.

ROSE-GROWING IN TOWN GARDENS.

Tea Roses.—Success with many of the Tea Roses is almost as much a matter of climate as of cultivation, and the inexperienced gardener will be well advised to commence with a few only of the hardier sorts. There are several strong-growing varieties which succeed well in most towns, and, on account of their fine qualities and continuity of flowering, these are of the greatest value, both for exhibiting and for decoration. It frequently happens that, by reason of its surroundings, a town garden is particularly sheltered, and Teas may be grown with some success; but they should always be placed in a position that will secure their protection from north or north-east winds, while giving them a full share of sunshine. Some kinds, such as the Cochets and Souvenir de Pierre Notting, which are mildew-proof, may be grown with advantage against a wall or fence having a southerly aspect.

The Best Soil.—Teas prefer soil that is lighter and warmer than is suitable for most other varieties, and a somewhat sandy loam liberally enriched with cow-manure forms an excellent staple. Heavy clay soils, which are naturally cold, need to be lightened considerably, and a quantity of leaf-mould should be added, as well as stable manure and road scrapings or other material. Many of the more vigorous kinds succeed well on standard stocks; but it must be remembered that when grown in this way it is the roots of the Briar which have to be catered for, so that they will do best in a heavier soil.

Flowers Not Opening.—One of the difficulties in growing Tea Roses is in getting the flowers to open, and there are two chief factors to success in this. The first is to maintain the plants in a healthy and vigorous condition, for a Rose that is a bad opener will seldom expand its blooms when the growths are weak. A great deal may be done to obviate this at pruning-time by cutting back to sound, plump eyes, and subsequently conserving the energy of the plant by rubbing out a number of the weakest buds. This should be done before the end of April. The second point is to protect the blooms during the opening stages, the usual method, and the easiest, being to place a Rose shade over each one. A more useful protection would be a light, glazed framework consisting of top and front only, which could be quickly placed and adjusted over any plant and as easily removed. One wonders that some enterprising horticultural builder has not already evolved such a contrivance, which would be invaluable to the exhibitor.

Easily Grown Teas for Bedding are Corallina, coral red; G. Nabonnand, flesh, shaded rose; Lady Hillingdon, bright golden yellow; and Mme. Antoine Mari, blush white. Those who prefer larger flowers should try the following kinds: Lady Roberts, buff, with orange and copper base; Maman Cochet, flesh, shaded yellow

and rose; White Maman Cochet, pale lemon; Mme. Jules Gravereaux, a semi-climbing variety, yellow, suffused pale pink; Molly Sharman Crawford, eau de nil white; and Mrs. Foley Hobbs, ivory white. Exhibitors will find many other Teas of great assistance, especially for autumn shows, some of the finest being Alexander Hill Gray, lemon yellow; Mrs. Herbert Stevens, white; Mrs. Edward Mawley, pink; Mrs. Myles Kennedy, creamy white; Mme. Constant Soupert, deep yellow, shaded peach; and Souvenir de Pierre Notting, apricot yellow. There is now a strong-growing climbing form of the last named, which, I understand, is a great improvement upon the dwarf variety and opens better. Climbing White Maman Cochet has also found its way to this country, and is sure to become a favourite when it can be obtained at a popular price, as it makes an ideal climber for a south wall.

P. L. GODDARD.

THE LATE PLANTING OF ROSES.

PERHAPS there is no greater fallacy entertained by the man in the street than that regarding planting Roses in late spring. People have remarked to me, even in February, "I should like to plant some Roses, but I fear it is too late." I have, fortunately, been able to show them beds of Roses planted even in April that quickly dispelled such an idea from their minds.

Excepting for special circumstances, I do not wish readers to infer that spring planting is preferred to autumn planting, as that would be going against all experience of practical men; but I do say that no one need hesitate to plant Roses now, and for another month to come, with a certainty of a fine display this year.

Some Advantages of spring planting may briefly be stated. First, as regards tender varieties, late planting is undoubtedly in their favour. The producer has means of protecting such Roses, even if we experience severe weather; whereas, if the amateur plants them in his garden, the chances are they would be lost. Doubtless many readers of THE GARDEN live in especially cold and wet districts. If that is so, they will do well to defer their planting until spring. I do not say one should defer ordering, but I would suggest, rather, that the plants be procured and "heeled" in the soil in a shady, sheltered spot, there to remain until all signs of winter are past.

Another Advantage of planting late is that our Roses are largely enabled to escape May frosts. These, as is well known, cause much havoc among the excitable Roses, such as the Teas and some of the Hybrid Teas; but if their growths are retarded by late planting they do not suffer, or, even if they do, it is of very little moment. Then, again, a modern Rose garden is frequently in full beauty in October, and how can one think of alterations while such a show of bloom abounds! Are we not prone to wait until the winter evenings before we formulate our plans of renewal or extension? There is yet one more advantage that may find favour with some individuals, and that is the fact of tempting bargains being offered by our Rose-growers in

the spring months, a detail that will appeal to many. To make late planting successful, one must be extra careful of the

Preparation of the Soil. We often see the advice given to amateurs to trench their soil in the autumn, even if they cannot plant until the spring. This might be sound advice for those having a light soil, but for clayey loams it is a bad practice. I have found it much more preferable on my heavy soil to wait until such time as I am ready for planting. Thus, instead of having the beds or borders saturated with the winter rain and snow, by waiting until a favourable moment for the preparation one may trench, and the planting follow immediately before the soil has a chance of becoming saturated. Nothing is so inimical to successful Rose culture as to be obliged to plant when the ground is of the consistency of soft putty.

Preparation of the Plants.—It is important that Roses planted late should be pruned back hard either before or immediately after planting. It is also advisable that they should be in a dormant condition. Many growers dig up the plants and place them in beds, and they are kept moved, so that when sent out the eyes are dormant. At all times when planting Roses a shovelful of nice compost should be given to each plant, as this, being of a fine nature, will percolate among the fine roots, and if the latter are dipped in a bucket of water first and some of this fine soil is dredged upon them, successful planting is practically assured.

Firm Planting is another very imperative detail. Not only should the soil be made firm at the time of planting, but, a week after, it is well to go over them again and set the heel against each plant. I would also advise that before placing the final covering of soil, a good watering should be given; then, after the water has been allowed to pass down, the final soil placed in position, but no treading of the soil should follow at the time. Although I am averse to mulching Roses planted in the autumn, I strongly advise a thin covering of well-rotted manure being applied immediately after the spring planting, partly to prevent that cracking of the soil by the drying winds of spring and partly to conserve the moisture. Peat moss litter would come in very useful here if not too strong. I fear many Roses are destroyed by giving them mulchings of strong manures before they have had time to establish themselves. On no account should powerful chemical manures be so applied.

How Late May One Plant.—This depends largely upon the season, but, generally speaking, Roses from the open ground may be planted as late as the middle of April. After this time pot-grown plants should be employed. It is an excellent plan, if beds of a kind are planted, to pot up a few reserve plants of each sort, in case of failures. Such pot plants may be sunk in the soil in their pots, and will prevent one having gaps in the Rose-beds during the summer. If any readers are contemplating exhibiting blooms from spring-planted Roses, I must warn them of probable disappointment; but for all who desire a beautiful display for their garden, and especially for the coming autumn, I can assure them they will be well pleased if the foregoing details are followed. Reasonable care is, of course, necessary, but I think I have made it clear that those who wish to do so may safely plant beds of Roses during the next few weeks.

DANECROFT.

HARDY HEATHS.

RETURNING to a subject which I some time ago endeavoured through the pages of *THE GARDEN*, to bring as prominently as I could under the notice of its readers, I must, in the first place, admit that in the interval I have learned that hardy Heaths are by no means so fastidious in regard to soil and situation as was at one time thought; indeed, from several letters I received appreciative of my former effort, the writers informed me that in their cases, and contrary to my advice, they found many varieties of Heaths thriving well in stiff, heavy soils. One in particular, who seemed to possess a large and full collection, assured me that his soil was a heavy, clayey one, and that the plants were thriving luxuriantly. I may here say that all my correspondents wrote from the Southern Counties of England, so that, from the evidence given, one need not be deterred from forming a Heath garden simply because he does not possess a light, sandy soil or facilities for making a compost of peat resembling the soil in which these plants are generally found growing in their native habitat. The only drawback in regard to heavy soils would be that propagation could not be so easily effected, and that a thorough system of drainage would require to be carried out before any measure of success could be attained. If we study for a short time the habits of our native Heather, *Erica* or *Calluna vulgaris*, it will be found growing both on the dry hillsides and in marshy places. In the latter, however, the Heather is always patchy and confined to little knolls over the bog. As we ascend, however, the plant becomes more scraggy and stunted, until, among bare, dry rocks, it ceases to gain a foothold, and fringes off with an odd plant here and there, attaining a height of only a few inches.

On the upland flats, at a moderate elevation, where a good depth of black, peaty soil is found, one can wade through the Heather almost waist deep, showing that here are to be seen the most favourable conditions for its growth, and those that must be copied to a certain extent if a full measure of success is expected. It is often a difficult matter to select a suitable position for the Heath garden, especially if the existing arrangements are of a formal character. It cannot very well be associated with beds of brilliant-flowering subjects such as are usually designated bedding-out plants, neither can these plants be dotted or clumped effectively in the herbaceous border. I have seen them, however, used with a fair measure of success on the margins of a large shrubbery, where they were quite in harmony with the flowering shrubs, and at another time on the boundary line of an extensive rockery, where they were planted in groups with a huge, natural-looking boulder peeping out here and there, the whole

arrangement being so cleverly executed that it was difficult to decide what really intervened between the actual rock garden with its alpine occupants and the wooded slope beyond; but there are few places where a suitable spot could not be found for planting a collection of hardy Heaths. It may be abutting on some woodland walk, in an open glade surrounded by trees, or enclosed with a hedge having a rustic summer-house in one corner, or on a steep, sloping bank where the plants can be viewed either from a high or a low level. They must, however, have an open, airy situation and be free from the shade or influence of large trees. If the soil is poor, it can be improved by the addition of manure and leaf-mould, for while the Heath will grow and flower well on thin and almost barren soils, it responds readily to a more generous fare, and to ensure success it is advisable to provide a suitable compost. Thus, a rich, heavy soil should

A HEATH GARDEN ON A HILL SIDE.

have a considerable quantity of peat, leaf-mould and sand added and thoroughly mixed together. Light, sandy soils will only require the addition of a good dressing of well-decayed farmyard manure, but an open position is desirable whatever the soil may be.

The numerous and varied forms of hardy Heaths, their hardiness and long season of flowering, covering as it does almost every month of the year, entitle them to more than passing notice, and I hope that the present fashion for creating rock gardens will soon extend itself so as to embrace Heath gardens as well, the conditions as to site and exposure suitable for rock gardening being easily adapted to the requirements for forming a Heath garden. In my next article I propose dealing with a Heath garden at present in course of construction in the heart of the Grampians.

THOMAS WILSON.

(To be continued.)

THE SNAPDRAGON AS A GARDEN PLANT.

FOR a long period in the nineteenth century the Snapdragon was regarded as a florist's flower, striped or barred, of which the finest form was one named *Hendersonii*. At the same time there was a strain now merged in the intermediate section, which was utilised in the furnishing of flower-beds, especially in those districts in which, owing to climatic disabilities, *Geraniums* could not be profitably employed. The finest of all the crimsons is still one that originated at Lord Ravensworth's very many years ago. Queen of the North and Yellow Perfection are varieties which also have been in cultivation for a lengthened period; but the æsthetic colours, both in the tall and in the intermediate sections, which have

made the *Antirrhinums* so popular, are wholly, or almost wholly, the production of the present century.

There exists a certain degree of dissimilarity in the habit, and also in the flowers, of both of these sections, some of the intermediates being so tall as to almost merge into the tall section, of which there are varieties of comparatively low stature and weak constitution. There are in the flowers, broadly, two types, the one rather small and narrow, the other broad and about three times larger, and these, too, are of the tallest growth, sometimes attaining a height of 6 feet and even 7 feet, the white and yellow being, perhaps, the most vigorous of all. Along with the Tom Thumb section we have, therefore, a choice of Snapdragons ranging in height from 6 inches to as many feet, with a marked dissimilarity of habit, and, along with a charming range of colours, a certain diversity of form.

Raising Plants. The plants are so easy of production that it need only be said that seeds for flowering the same year may be sown any time up to March, providing a smart temperature for germination is given, and afterwards growing them comparatively cool. The seedlings are apt to damp if wetted when small; therefore, dipping the receptacles in water must be resorted to when the soil requires moistening, and, if damping occurs, some fire-dried sand should be sprinkled over the surfaces, which checks and usually stops the trouble. Pricking out the seedlings when quite small into boxes or frames also stays the progress of the mischief. At this stage the leaves of every plant should be examined, best on the under sides, and all rejected which vary from the majority, because the plants assuredly will, on flowering, turn out to be "rogues," and, of course, when planting in beds, any that have escaped notice at this examination will be set aside then.

Varieties, or at least names, have increased to a perplexingly large extent within the last year or two, and for the beginner in their use it would be desirable to purchase from one seedsman only. I am growing this year some two dozen kinds of intermediate and tall derived from different sources, but most are well known already, and the remainder will be planted where any disabilities they may develop will not affect the general appearance of the garden. But no one can go wrong with, in tall varieties, White, Cloth of Gold, Golden Chamois, Fire King (or Orange King), Carmine Pink, Crimson and Gold, and Rosy Morn. These, I think, are the cream, though Moonlight, if properly associated, may also be added. I know of no very good crimson, and grow crimson, scarlet, rose and a cream form of Rosy Morn from cuttings, none of these coming true enough from seed to give satisfaction. Of intermediates are Yellow Queen, Queen of the North (white), Carmine Pink, and any pink, indeed, is worth growing, Bonfire (apricot), Light Apricot, Fire King (brighter than Orange King) and Oliver's Crimson, if it can be obtained. It should be noted that a group of the old florists' type of variegated flowers is by no means to be despised.

Arrangements of Colours.—Though easy enough to produce, Snapdragons are not quite so easy to arrange to be effective. This is on account of the colours clashing when a number are employed indiscriminately, or when associated with plants with which the colours do not go well. The tall white, with Dropmore Anchusa or Salvia patens, is really splendid, and Cloth of Gold associates equally well with Anchusa Opal, Golden Chamois and the dark blue Branching Larkspur, or with Lobelia cardinalis varieties is strikingly beautiful, while all the pink shades go with yellow.

orange and mauve. But Snapdragons are never more charming than when used by themselves in colours properly matched. My own rule is to detach pure white and yellow from the others; not that they cannot be associated effectively enough, but I do not think they add anything to compositions equally, if not more, effective when either is absent; but that, of course, may be a mere personal whim. Tall Golden Chamois, Carmine Pink and Light Pink with the intermediate Carmine Pink provide a very lovely combination. So do the apricot shades with Fire King, both tall and intermediate, and the series of pink shades along with the apricots is very nice, though I am rather dubious if the deep apricot of Bonfire were

A CARPET OF SPRING SNOWFLAKE (LEUCOJUM VERNUM) AT WISLEY.

not better left out. As a rule, beds or borders furnished with Snapdragons should be filled entirely with them, an edge of another kind of plant always detracting from the value of the colour mass as a whole.

I should add that, although we have Snapdragons thriving on walls, to do them well requires very thorough and good cultivation. The finest I have ever seen were in Herefordshire, growing in made-up beds of turf and loam, in which some of the spikes rose to a height of 7 feet. A pigmy of 2 feet or 3 feet compared to these is simply nowhere, although it might perhaps appeal to some.

R. P. BROTHERSTON.

COLOURED PLATE.

PLATE 1489.

A NEW PERPETUAL-FLOWERING CARNATION.

THE new Perpetual-flowering Carnation Gorgeous must be considered an epoch-making variety, for all who have seen it have been enraptured with it. It has a strong, clean, healthy growth, a wonderful stem, and a calyx which rarely bursts. The colour is of a rich glowing cerise with the clearness of Aristocrat, but with none of this variety's weakness in its young state. When the flower is about half open, it has a yellowish, glistening sheen on its petals, which gives it a sunray cerise tone, and under artificial light it stands alone for the brightness of its colourings, giving way to a glowing scarlet; in short, we might quote a passage from Charles Kingsley's "Westward Ho": "There is nothing like it under the canopy of Heaven." It has come to stop, and will be what Enchantress has been in the past. The honours awarded to this variety are an award of merit from the Perpetual Flowering Carnation Society, an award of merit from the Royal Horticultural Society, and certificates of merit at Liverpool and Bristol. We are indebted to Messrs. Stuart Low and Co., Bush Hill Park, Enfield, for the flowers from which our coloured plate has been prepared.

SPRING SNOWFLAKES.

ONE of the most delightful flowers now to be seen in the Royal Horticultural Society's Gardens at Wisley is the Spring Snowflake (*Leucojum vernal*). It has naturalised itself in many places, and may be seen flowering among the Crocuses and Polyanthuses in the borders, or producing its drooping, bell-shaped flowers in out-of-the-way parts of the wild garden. One of the most pleasing effects is a carpet of Snowflakes flowering freely under the bare canes of a cultivated *Rubus*.

CHINA ASTERS IN THE WOODLAND.

THE illustration on page 133 shows a picturesque grouping of the China Aster naturalised in grass under the partial shade of trees. The means whereby this effect was produced are somewhat curious, as it was the result of accidental sowing. The ground under the trees had been cleared and dug over preparatory to sowing it down with grass. By a misunderstanding among the workers, both grass and Aster seeds were sown over the same patch of ground. The result, however, is so pleasing and natural that it is worth noting, as it is a simple way of converting a waste piece of ground into a place of unusual splendour. The Asters were sown in April, and flowered well through August and September.

SIX BEAUTIFUL DWARF ANNUALS.

ALTHOUGH the widely cultivated Stocks and Asters are very beautiful, I often wonder that some of the other half-hardy annuals are not more often met with in quantity. There seems to be in many quarters an antipathy against trying anything new, and the result is that we come across the same kinds of flowers year after year in gardens; whereas, by having a little more variety, a much more interesting display would be forthcoming. The six kinds I have selected are such as one seldom sees

ture until growth is well started and the weather fairly settled, when they should be removed to a cold frame. Give abundance of air and harden off by the middle of May, when they ought to be planted out in fairly rich soil and in a sunny position. While all these annual (or biennial should I say?) Pinks are beautiful and useful, I, personally, prefer a good strain of the Hedderwigii type. Single and double are equally worthy of extended cultivation, and no garden should be without them.

Dimorphotheca aurantiaca.—This comparatively new plant, introduced from South Africa by Messrs. Barr, is a most telling bedder in a sunny season. I have grown it every year since its introduction, and it never fails to draw attention

little else will grow, but it should have a position in full sunshine if it is to give of its best.

Larkspur.—Although the dwarf forms of this grand plant can never compare with the tall, branching kinds, still, they are very valuable for small beds and for small gardens where space is at a premium. The dwarf Rocket Larkspur is so cheap that the seed may be sown where the plants are to bloom, and can then be thinned out to 4 inches or 5 inches apart. The dwarf Stock-flowered type is worth the trouble of raising in boxes and being treated like a half-hardy annual. Sow towards the end of March, for if raised too early the plants are apt to become unhealthy before the weather is favourable for planting them out. Fairly rich, well-tilled soil should be given

SINGLE CHINESE ASTERS IN AN OPEN WOODLAND. THESE WERE THE RESULT OF ACCIDENTAL SOWING.

in quantity in any garden, and it is in the hope of arousing a little interest in these beautiful flowers that I now write. I refer to Dianthus, Dimorphotheca, Jacobea, Larkspur, Nemesis and Phlox Drummondii.

Dianthus (Pinks).—The Indian and Japanese Pinks, when a good strain is obtained and well grown, are hard to beat for filling small beds or borders and for cut flowers. Seed should be sown thinly in pans or boxes early in March and placed in gentle heat. The seeds germinate very rapidly, and care must be taken to prevent the little plants becoming drawn and weakly. Prick off into boxes of good soil as soon as large enough to handle, and return to the same tempera-

ture from all visitors. Those who like mixed colours should grow the new hybrids, for they give some pretty shades besides white. Seed should not be sown before the middle of March, and the end of that month is not too late for it. Treat it exactly like Stocks in the way of sowing, pricking off, and subsequent treatment. Plant out at the end of May in good soil and in the sunniest spot available.

Jacobe.—This Groundsel is usually classed as a hardy annual, but here in Scotland I find much the best results are obtained by treating it as half-hardy. Sow at the end of March, plant out towards the end of May in rather poor soil, and a really fine display of bloom will be forthcoming. This plant will often thrive where

this plant, and if the position is exposed and staking necessary, then place the stakes at planting-time, for the roots of these Larkspurs are very easily damaged.

Nemesis.—This is without a doubt the most beautiful of all dwarf annual flowers, and should be much more widely cultivated than it is at present. Many sow the seeds much too early, and also place the seed-pans in too high a temperature. Nemesis seeds will not germinate strongly nor freely in a temperature much over 60°, and the last week in March is the best time for sowing. Prick off into boxes of fairly good soil and in good time, and do this with extra care, for the Nemesis in its earlier stages is rather delicate. When it

starts fairly into growth, after being pricked off, all danger is past, and the plants should be kept near the glass in a moderate temperature. At the beginning of May remove to a cold frame, harden off gradually, and plant out early in June, choosing rich, deeply dug soil and a sunny aspect. While the large-flowered form is very rich and

ROCK GARDEN PLANTS FROM SEED.

A BRANCH of gardening alike interesting and profitable, and having special attractions for the amateur, whose delight it is to garden among rock plants, is found in raising these and kindred

THYMUS ODORATISSIMUS, A FRAGRANT PLANT FROM RUSSIA. THYMES ARE EXCELLENT SUBJECTS FOR THE ROCK GARDEN AND MAY BE RAISED FROM SEED SOWN NOW.

beautiful, I much prefer the dwarf hybrid strain of Messrs. Sutton. This firm has greatly improved the colours of this section of late years, and a bed or border filled with this grand *Nemesia* takes some beating. The plants branch so freely that about twelve inches asunder is the proper distance to plant if a really effective display is aimed at. The large-flowered type must be planted much closer, say, from 7 inches to 9 inches.

Phlox Drummondii.—When well grown, this is only second to the *Nemesia* for beauty and effectiveness. The seed should be sown during the last week in February or early in March, and be grown steadily on in a slight warmth until the plants have reached a fair size. *Phlox Drummondii* is well known to be one of the easiest of all annuals to cultivate. Even in town gardens it will succeed, while it is usually one of the first subjects to bring to the notice of children who show a fondness for garden flowers. Nevertheless seed must be sown thinly and thinned early. For filling small beds or for making an edging for taller plants they are equally effective. Soil of a fairly rich nature gives the best results. All the sections are good, but for general usefulness the intermediate is preferable. If a really fine strain of this is procured, a grand display is certain.

C. BLAIR.

Preston House Gardens, Linlithgow.

subjects from seed. It is hardly possible to overrate the amount of healthy recreation this delightful pursuit affords; it yields an enormous amount of information that cannot be acquired otherwise, while it furnishes a splendid stock of plants, either as the nucleus of a collection or for augmenting that already in existence. The actual procedure in the raising of alpine plants from seed does not materially differ from that practised with the choicer kinds of annuals of a tender or half-hardy nature, except that they entail more attention to details in the initial stages.

Best Time for Sowing.—The spring months offer the best season in which to start, as this gives a long growing season and enables plants of a presentable size to be obtained before the ensuing winter.

Proper Soil.—The method I generally follow is to sow in pots, pans or shallow boxes, according to the rarity of the variety. The receptacles are provided with liberal drainage and partly filled with a moderately coarse compost consisting of yellow loam, leaf-soil and sand in equal parts, this being passed through a half-inch sieve to complete filling the receptacles. The seed-bed should be quite level, and, as many of the seeds are very small, they scarcely want covering at all, while the larger seeds, like those of *Androsace*, *Dianthus* and *Iberis*, will bear covering to a depth of an eighth of an inch.

Watering the Seeds.—To those unversed in watering fine seeds with water-pot and rose, a safe method to employ until the seedlings are large enough to handle is to stand the pots and pans almost to the rim in a tub of water; by this means the seed is not displaced, as may readily follow from the careless use of a water-pot. After sowing, place the seed-pans in an ordinary greenhouse or in a frame upon a slow hot-bed, and cover over with a square of glass. This hastens germination, and, as the seedlings appear, gradually tilt the glass covering to admit air till, eventually, it can be dispensed with altogether.

Treatment of Seedlings.—Once germination takes place, the seedlings must be kept well to the light, and from this stage onward an unheated garden frame will give the best results, using sun-heat alone to maintain a growing temperature. When the seedlings are large enough to handle, they are pricked out into pans or boxes, using a compost as advised for seed-sowing, to which one part of rough grit is added. In pricking out and all subsequent potting, keep the soil moderately firm, otherwise growth will be coarse and sappy and the plants will give more trouble in hardening them off for permanent planting outside. Once the plants come to a fair size—in the case of the more robust kinds this will be some time in June, if sown during March—they may be potted singly and then plunged in nursery rows or in beds of coal-ashes. This method reduces the amount of attention necessary to keep them supplied with moisture, and it ensures stocky, hard-grown plants, such as rarely fail to give satisfaction when used in the permanent scheme of the garden.

Seeds Remaining Dormant.—Many kinds of alpine plants, among which *Primulas*, *Gentians* and some *Saxifragas* may be cited as examples, lie dormant some time after sowing, and where this occurs the seed-pots must be kept nicely moist, with the glass covering on, until either germination takes place or it is seen that the seed is useless. Some *Primulas* and *Gentians*, however, will germinate after being sown twelve months. *Ramondia* is typical of a class of alpine that exacts much care the first season; the seed is so small that the tendency is to sow too thickly, and, as it is usually several months before it is even possible to pick up the seedlings, much less handle them, the necessity for sowing thinly becomes obvious.

The great majority of the rock and alpine plants that can be raised from seed will flower in the year following that in which they were sown. These include *Æthionemas*, *Alyssum*, *Androsace*, *Anemone*, *Arenaria*, *Aster alpinus*, *Campanulas*, *Dianthus*, *Drabas*, *Erinus*, *Geranium*, *Gypsophila*, *Hutchinsia*, *Hypericum*, *Iberis*, *Leontopodium*, *Lithospermum*, *Phyteuma*, *Primula*, *Saponaria*, *Sedum*, *Silene*, *Tunica*, *Veronica*, *Viola* and *Wahlenbergia*. Among those that do not flower till a later period, besides the exceptions already noted, are *Lithospermum Gastoni*, *Ramondia*, *Thymus*, *Gentians* and *Saxifragas* like *burseriana*, *lantoscana* and *longifolia*.

THOMAS SMITH.

Coombe Court Gardens, Kingston, Surrey.

THE JAPANESE OR CAPE PLUMS.

CAN THEY BE GROWN IN THIS COUNTRY?

AMONG the foreign fruits which invade our markets at the present season, one of the newest comers is the Cape Plum. This fruit so differs from the Plums commonly known in this country that many curious legends are current as to its origin. The matter, however, is wrapt in no mystery and is of great interest, as these Plums are among the newest fruits which we owe to Eastern Asia, and their culture in America is already great. The wild species from which this race is developed is *Prunus triflora*, a native of China, and its garden varieties are there cultivated in a rather haphazard way. When imported into Japan it gave rise to very many new varieties, of which the nomenclature is, unfortunately, very uncertain. The pointed varieties are grouped under the name Hattankio, and the round ones Botankio, while the general name for these Plums as a whole is Sumomo. Some seventy-seven varieties are named in a list before me, a few of which are now known in many parts of the world.

About the year 1870, American growers began to interest themselves in this fruit, and importations were made, notably by John Kelsey of Berkeley, California. A perfect boom in Japanese Plums then began, and new sorts were imported and seedlings raised, and the nomenclature was soon in a state of the wildest confusion. The fruits themselves, however, prospered, and have now become a large and important source of fruit supply in the United States. From America they were imported to the Cape, where the climate suits them admirably, and they thus reached our shores by a roundabout route, gathering on the way yet another name, "Cape" Plums.

The principal varieties now grown are Botan, or Abundance as it is more generally known in America; Burbank, a Japanese variety renamed after the much-advertised raiser of fruits and flowers in California; Chabot, Hale, Kelsey, Maru and Shiro. Wickson, a large and excellent fruit, is the result of a cross between *P. triflora* and *P. Simonii*, also a native of China.

As to the adaptability of these fruits to the English climate, experiments so far lend no hope to this possibility. Burbank has fruited occasionally, but all the other sorts are too tender in most places for open-air culture unless on a wall. The extreme earliness of the blossom is often, too, a cause of failure, both on account of severe weather and the lack of insects for pollenising. It is stated in America that the Myrobalan (*Prunus myrobalana*) or Cherry Plum is a good polleniser for all the Japanese Plums, and where one sort only is grown, a plant of this would be valuable, as it flowers at the same time.

Under cool orchard house culture, however, these Plums succeed

admirably, and the fruit is extremely good both to eye and palate. The best sorts for this culture are, as far as I have tried, Burbank, a beautiful, transparent, round fruit; Botan, a pointed fruit, large, dark red and extremely rich; Shiro, pale creamy yellow, remarkably juicy; and Wickson, an enormous, pointed, rich crimson fruit. A remarkable feature of all these Plums is the extraordinary amount of blossom produced. Burbank is often so thickly set with bloom that it is literally impossible to see the wood for the flowers. The resulting crop, however, is not usually more than normal.

In conclusion, these fruits can be highly recommended for glass culture. They should be tried on walls, and in the warmer parts of this island they would probably succeed as standards or pyramids in the open.

Maidstone.

E. A. BUNYARD.

SEASONABLE NOTES ON VEGETABLES.

Parsnips.—Owing to the continuous rains during February, the sowing of Parsnip seed was delayed. No time should now be lost in doing this work. Deeply trenched soil that has been previously manured for a former crop is the best. With an iron bar make holes 3 feet deep, filling the holes with a compost of fine gritty soil. Sow two seeds in each hole, the holes 15 inches to 18 inches apart, the rows 2 feet wide. This method prevents the roots becoming crooked, as they often are in stony soil without this special preparation.

Turnips.—Sow a pinch of seed of White Milan in a frame on a slight hot-bed to give an early supply of small roots. On a warm, sheltered border sow in drills in prepared soil, also a pinch of seed of Red Milan, as, with genial weather in April, nice roots may soon be obtained.

Celery.—For use in August and September seed should now be sown quite thinly in boxes in sandy soil in a temperature of about 55°. Directly the seedlings are up, place the boxes on a shelf near the glass, so that the growth made shall be of a stocky character. If the plants become drawn owing to overcrowding or too much heat, they are quickly ruined, and it is a waste of time to continue their growth. Giant White and Aldenham Pink are good varieties.

Rhubarb.—An open site, with ample space between the roots for full leaf development, and a deeply trenched and heavily manured soil are the salient conditions necessary to ensure success. Plant single crowns just under the surface 4 feet apart, and as much or more between the rows. After planting, fork over the ground among the plants, and mulch lightly with half-decayed stable manure. Royal Albert for forcing, The Sutton for general growth, with Champagne and Victoria for ordinary use, are desirable varieties.

Tomatoes should be sown at intervals as space can be found under glass for the plants. The chief point is to avoid overcrowding. Grow the plants near the glass to avoid weakness, and pot on as required. Many failures with Tomatoes in the open can be traced to faulty management of the plants, especially in sowing too late, which does not enable the plants to be large enough at planting-time. The middle of March is a good time to sow seed for outdoor growth. The plants should be vigorous, of full size, and thoroughly hardy when put out. Should they show signs of turning yellow owing to being pot-bound previous to planting, give them liquid manure freely. Sunrise for indoor growth and Holmes' Supreme for outside are good. Dobbie's Golden Drop is an excellent small-berried yellow sort for outdoors.

Spinach is such an increasingly favourite vegetable that more encouragement should be given it. Frequent small sowings are better than

THE CAUCASIAN CATCHFLY (SHELLY-HAFTAL) GROWN FROM SEED

those larger and less often. On a warm, sunny border the first sowing should be made; afterwards, between rows of Peas and Runner Beans. Round-seeded and The Carter are desirable varieties, with The Victoria for a main crop.

Potatoes.—Now is a good time to make the first plantation of May Queen, Sharpe's Victor and Myatt's Ashleaf for the earliest crop. At the foot of a south wall or on a warm, sloping border is the best site. The tubers having been sprouted previously in a cool place, plant them 15 inches apart in rows 2 feet wide, covering the tubers with a prepared sandy compost in which decayed leaves figure freely. Too much attention cannot be paid to the sprouting of the tubers in a cool and dry place. Neglect in this direction may lead to disappointment.

Radishes should be continuously sown at brief intervals in Potato, Carrot or Asparagus forcing-frames. An outside sowing on a warm border should be made, covering the bed with straw to encourage early germination of the seed and to protect the tiny plants, as they peep through the soil, from birds of the linnet type.

Peas.—A sowing in the open of such varieties as The Pilot, Edwin Beckett or Sutton's Early Giant should be made, covering the seeds with decayed leaf-mould or old potting soil, which encourages quicker root action than the ordinary soil, which is still cold.

Swanmore. E. MOLYNEUX.

PEAS: CULTURAL HINTS.

GOOD, fresh Peas are generally appreciated, and every pains should be taken to produce these in the best possible condition over as long a period as possible. Thanks to those who have given so much time and trouble during recent years to hybridising and selecting so many varieties, both early, midseason and late, much less trouble will be experienced than was the case only a few years ago. Undoubtedly it is much easier to have good Peas for the table from the middle of June to the end of the second week in July than at later dates, and almost everyone possessing a garden has little difficulty in having them at this season. By the time these lines are in print the seeds will have been sown and be well on the way for the early crops, and my remarks on this occasion are intended principally for successional crops.

The garden Pea is a deep-rooted subject, and during spells of drought will penetrate deeply in search of food and moisture if such soil be made amenable, so that in all cases the ground should be broken up at least 3 feet in depth, placing plenty of good farmyard manure in the bottom of the trench. This work is best done

during the winter or early spring. Unquestionably the best method is to prepare trenches precisely in the same way as one would for Celery, and especially so for late varieties and on dry, porous soils; the application of manure and other suitable compost is rendered much more easy, as well as being much more convenient for watering purposes. Such trenches should always be prepared, when possible, some weeks previous to the seed-sowing; the soil thus becomes sweetened

done just as thick again as it is intended for the plants to remain, which should be thinned out as soon as the young plants are 2 inches or 3 inches in height. Naturally, the strongest and tallest growing kinds require more room than those of less robust habit; but in nearly all cases of the better kinds of Peas the plants should not be left thicker than 3 inches apart. Always sow two lines in a trench, and, where mice and other vermin abound, the seed should be rubbed in red lead and allowed to dry before using. At the same time, means should be taken to trap mice or rats. It is always wise to set some tempting baited traps for mice, whether they are known to exist or not. At the time of sowing, a little bone-meal should be sprinkled along after the seed is sown; this will prove a splendid stimulant. Care should be taken to protect the young growths from the ravages of birds immediately they appear above the ground. This is best done by straining three lines of black cotton about four inches above the surface of the ground.

Staking.—As soon as about four inches of growth is made, staking should be proceeded with. Though there are several inventions for supporting Peas, I have not yet come across anything to supersede, or even equal, ordinary brushy wood stakes. This task should be carried out in a pleasing and workmanlike manner, thrusting the ends well into the ground sufficient to withstand any wind pressure. The tops should be taken off and placed between the stakes, with a view to conducting the tendrils to the larger stakes. To ensure a regular supply during the late summer, sowings should be made at intervals from this date to the middle of June.

Mulching.—I regard this as of the greatest importance on all kinds of soil, nothing being better for the purpose than short stable litter. It has a wonderful influence, of prolonging the crop, especially during spells of dry weather.

Watering.—The plants will be much benefited by applying frequent drenchings of water to the roots, both clear and in a liquid manure form, during dry spells, always using water, if possible, which has been exposed. It is equally as important and beneficial to syringe or damp the growths thoroughly after a hot day with clean tepid water; this is best done in the early evening. When extra large pods are required, either for exhibition or other purposes, the growths should be stopped, side shoots cut away and the pods thinned.

Varieties.—Though, as before stated, there are many excellent varieties, I propose to give a short list of what I believe to be among the very best and in their order of sowing: Duke of Albany, Prodigy, Alderman, Stourbridge Marrow, Quite Content, Centenary, Gladstone, Rearguard, Masterpiece and Autocrat. EDWIN BECKETT, V.M.H.

THE SAME BED AS SHOWN ON THE OPPOSITE PAGE, SHOWING THE EFFECT OF SOWING CANDYTUFT BETWEEN DARWIN TULIPS.

and in a much more workable condition than when left till the last moment, though sometimes this cannot be avoided owing to the ground being occupied.

Sowing the Seed.—In the large majority of cases the seed is sown much too thickly, the result being anything but satisfactory. I am convinced that there are far more failures due to this cause than to any other. In many cases one will see rows of Peas left almost as thick as Mustard and Cress, and expected to produce a crop. Surely if one would only give it a thought, it is unreasonable to expect a dozen plants to succeed when one would suffice, the result being that the plants become starved and in many cases eaten up with mildew, and, after a picking or two, the plants become exhausted. The best plan is to sow the seed singly at regular intervals, and this should be

GARDENING FOR BEGINNERS.

ANNUAL FLOWERS IN ASSOCIATION WITH OTHER PLANTS.

TO the beginner in gardening, especially if his or her garden is of small size, there are few more useful flowers than hardy annuals, and few that will give such a bountiful return for a small outlay of time and money.

Indeed, these annuals, which may be sown in the open garden, may be looked upon as a sort of sheet-anchor for the novice, to fill up blank spaces where perhaps some more ambitious gardening scheme has gone awry, or to fill the hiatus caused by the passing of spring-flowering perennials or bulbous plants. The gardener in a large establishment can rely upon pot plants or nursery stock to make good these gaps, but the beginner can seldom afford this, and still less frequently has the facilities for carrying it into effect.

Too often, bulbs, especially the May-flowering Tulips, are a source of great worry to the amateur. Owing to their late flowering and subsequent ripening of the foliage, they cannot with safety be removed from beds or borders sufficiently early to admit of the planting of the ordinary bedding plants, and for this reason many forego the pleasure that these bulbs are capable of providing and ban them from their gardens. This is a great mistake, and one that can easily be obviated if we would make more use of hardy annuals. Early in April seeds of these can be sown between the bulbous plants, and, by the time the latter have finished flowering and the leaves have died down, the annuals will be well on the road towards the flowering stage, and the bulbs none the worse for the association. Even beds of Daffodils may be successfully treated in this way, and if the bulbs are lifted in early autumn, before they have made extensive new root growth, and replanted at once, they will be in much better condition than if they were lifted this spring, before their foliage had properly ripened, to make way for the usual Fuchsias, Calceolarias and Zonal Pelargoniums that are so often relied upon for the summer display. It is true that these bedding plants commence to flower almost as soon as they are planted, and that the annuals seldom commence before July; but the four weeks or so that the beds or border spaces are without blossoms is not noticed in a garden of mixed flowers. It is mentioned to prevent possible disappointment to would-be growers of annuals.

Apart from those kinds which can be sown between the bulbs or spring-flowering perennials, there are many half-hardy sorts that may be raised in frame or greenhouse and planted out

between the permanent occupants during the early days of May. Into this category come Antirrhinums, China Asters, Stocks, Nemesis and Verbenas, all of which are capable of providing a glorious riot of colour during the late summer and autumn days.

There are just one or two simple cultural details that ought to be observed if success is to be assured with this association of annuals with perennial and bulbous plants. First of all, the soil needs some little preparation, especially if seeds are to be sown. I have always found it advisable to

of space from the outset. A weak seedling can never make a sturdy plant; hence it is necessary to lay a good foundation. This thin sowing, then, must be supplemented by a rigorous thinning of the seedlings at the outset of their existence. This is necessary even when annuals are being grown alone, but doubly so when in association with other plants. Just one other item. It will not materially harm the bulbs or herbaceous plants if just a few, a very few, of their largest leaves are removed to give the annuals more light and air during the early stages of their career. To bulb enthusiasts this will, I know, seem like rank heresy; but in gardening, as in everything else, it is advisable at times to adopt a policy of give-and-take.

There are a good many hardy annuals suitable for this association, such as Candytuft, Godetias, Clarkias, Virginian Stock, Mignonette, Alyssum, Leptosiphon, Nigella Miss Jekyll, Larkspurs, Shirley Poppies, annual Chrysanthemums, scarlet and blue Flax, and Pot Marigolds. The accompanying illustration may be of interest, as it represents a bed of Darwin Tulips edged with old-fashioned Pinks, and a plant of perennial Candytuft in the foreground. On the opposite page is an illustration of the same bed, from a photograph taken in the month of August. The Candytuft shown there was sown between the Tulips as advised, and the charming effect will readily be seen.

H. H.

A GOOD ANNUAL FOR THE GREENHOUSE.

BROWALLIA SPECIOSA MAJOR is such a pleasing little plant under quite ordinary cultivation that I wonder it does not become more popular. It is of the Solanaceæ Order and is almost hardy, but succeeds best when growing in the greenhouse or conservatory. The seed should be sown during March in shallow pans or boxes in a compost of equal parts of turfy loam, leaf-mould and sand, and kept near the glass. Pot up as necessary with a good fertile soil, shading from very bright sunshine. Some cultivators advise pinching the plants occasionally during the growing season, but

this I never do, as I think they are more graceful when left to grow quite naturally. Each winter my greenhouse is brightened with groups of these charming plants and their pretty blue flowers. Other good species of *Browallia* are *B. grandiflora*, which is also very pretty, with much smaller flowers than *B. s. major*, and *B. Jamesonii*, better known as *Streptosolen Jamesonii*, which has orange-coloured flowers and grows considerably taller than the two before-mentioned varieties. I. T. D.

A BED OF DARWIN TULIPS EDGED WITH PINKS. ON THE OPPOSITE PAGE THE SAME BED IS SHOWN FILLED WITH CANDYTUFT, SOWN BETWEEN THE TULIPS.

lightly point between the plants with a small fork, so as to get about two inches of fine, workable soil. Into this some superphosphate of lime, a large handful to a square yard, is well worked, as this provides food of a lasting character to the annuals just at their flowering period. Then, thin sowing is absolutely essential. Sturdy seedlings only are of any use for this kind of gardening, or, indeed, for any other; hence one must impress upon the beginner the vital importance

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Fig Trees in Pots.—Trees which were started in December should now be making good progress, and will require some stimulant to assist them in swelling their fruit. Guano is a very reliable manure for this purpose, but must be given in moderation. Pinch the shoots when a few inches long to encourage the growth of a second crop of fruit. Syringe the trees twice daily and shut the house early in the afternoon. A night temperature of 60° will be quite high enough, rising to 70° by day with sun-heat.

Peach Trees in Pots.—The earliest trees are now swelling their fruits, and should be watered with great care. If they are once allowed to become too dry at the roots, the prospect of a satisfactory crop will be much reduced. When the stoning period is over, liberal supplies of manure-water should be given. The final disbudding may now take place, leaving two or three well-placed shoots on each branch, some of which may afterwards be pinched to a few eyes from the base.

Melons.—If these are to be grown in flat pits or frames, no time should be lost in making up the hot-bed, which may be composed of two-thirds Oak leaves and the remainder of stable manure. The leaves create a mild and lasting bottom-heat, which is indispensable in the production of Melons in unheated pits or frames. In making up the beds for wooden frames, the material should be at least 3 feet larger than the frame, in order to allow a good quantity of fermenting material to be placed round the box when necessary. The soil may consist of turfy loam and a good sprinkling of old lime rubble. This should be placed in the pit several days before the plants are ready to put out. The mounds of soil should be at least 15 inches deep, and when warmed through should be made firm by treading. When two rough leaves have been produced, the plants should be carefully put out and the soil made firm. When growth commences, the tops should be pinched out and four shoots taken from each plant, and, trained on the surface of the bed, these will in due time produce numerous side shoots, on which the young Melons will appear.

The Flower Garden.

Border Chrysanthemums.—If the stools of these were lifted in November and placed in a cold pit, there should be no difficulty in finding plenty of sturdy cuttings now. If these are inserted in small pots of sandy soil and stood in a close, cold pit, they will soon make roots. Three cuttings may be placed round the edge of a 3-inch pot, and when sufficiently rooted they may be raised quite close to the roof glass and gradually hardened for planting at the beginning of May.

Seed-Sowing.—There should be no delay in sowing seeds of French and African Marigolds, China Asters, Ten-week Stocks, Phlox Drummondii, Zinnias, *Dimorphotheca aurantiaca*, *Dianthus* and *Rhodanthe*. All of these may be sown in a cold pit quite near the glass, and should be pricked off as soon as large enough to handle. Primrose and *Polyanthus* seeds should now be sown in the open border or in a cold frame to produce plants for flowering next spring. These should be transplanted 6 inches apart as soon as large enough.

Bedding Geraniums.—If the stock is at a short, no time should be lost in taking cuttings. If placed in 2½-inch pots and stood on a bed of fine ashes over a gentle hot-bed, they will soon make roots, and may then be potted into 4-inch pots. *Coleus*, *Iresine*, *Alternanthera*, *Lobelia* and *Ageratum* should be propagated as soon as possible, so that good, strong plants may be available by the middle of May.

Dahlias.—Early struck cuttings should not be allowed to become stunted for want of potting; but, as soon as sufficiently rooted, they should be potted into 5-inch pots and grown in a temperature of 50° quite near the glass. When established, air should be freely admitted. Cuttings may still be taken and placed in brisk bottom-heat.

Tuberous Begonias.—The tubers of these should now be started into growth. If placed in shallow trays and stood in a warm house, they

will soon make young growth, and should at this stage be potted singly into 5-inch pots in a compost of loam and leaf-soil in equal parts. Water carefully until the plants are established. After this stage air must be admitted in sufficient quantity to keep the plants stocky.

The Hardy Fruit Garden.

Alpine Strawberries.—If fruits of these are required during September and October, the plants may be raised from seed now. If sown in pans or boxes and placed in a temperature of 50°, the young plants will soon appear. Prick them into small pots when large enough and grow in a cold pit quite near the roof glass. These seedlings should be ready to plant out in May.

Figs.—The pruning and nailing of Fig trees on south walls should be finished as soon as possible. Let the old wood be well thinned out, leaving as many short-jointed shoots as possible without crowding. Figs are liable to make too much soft growth unless planted in restricted borders; but this may easily be avoided by building rough underground walls when the trees are planted. It is advisable to protect the trees from early spring frost by blinds.

The Kitchen Garden.

Peas which have been raised under glass for planting on a south border should be gradually hardened. The plants may now be fully exposed during the day by the removal of the lights. When sufficiently hard, they should be carefully planted out, and protected from cold wind by evergreen branches placed along the sides of the rows.

Young Pea Plants raised in the open garden will now be ready for sticks. Let these be placed in position with as little delay as possible.

Onions and Leeks sown in the early part of the year should now be ready for transplanting into boxes, and be allowed 3 inches or 4 inches between the plants each way. Keep close for a short time, and when established they should be freely ventilated in order to prepare them for planting out in the middle of April.

Celery.—Seeds should now be sown for the principal batch of Celery. Very little heat will be necessary if sown in boxes and placed in a slightly heated pit until the plants are through the surface. They may then be removed to a cold pit quite near the roof glass and protected from frost. The early batch of plants should now be ready for pricking into boxes of fine rich soil. These should be steadily grown without a check, and never allowed to suffer from the want of water at the roots.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—Plants that have been wintered in cold frames will perhaps be all the better for being planted out now if the weather is at all suitable. This will make room for other plants requiring protection. It will, however, be well to protect the young plants with some Spruce twigs. These will serve the double purpose of giving shelter and acting as a protection against game, particularly pheasants. A slight dusting of lime or soot will ward off slugs.

Onions.—Autumn-sown Onions may now be planted out, and if space is limited, they may be planted between the rows of some permanent crop, such as a new plantation of Strawberries. This crop of Onions will generally be found to be of great value when one has difficulty in getting the spring-sown Onions to ripen early enough.

Potatoes.—Another planting of early Potatoes may be got in, but in cold districts it will be better to wait until towards the end of the month before planting maincrop varieties.

Turnip-Rooted Beet.—Where one is expected to have a supply of early Beet for salads, I find it is a capital plan to make a sowing of the Turnip-rooted variety in frames about this date. They are much earlier than the long ones, and can be used when quite small. In growing in frames, care should be taken to give plenty of air, unless on very cold days, as Beet resents coddling.

Tomatoes.—For those who only grow one crop of Tomatoes, the present is a suitable time to get the seeds sown. Sow very thinly, and as they only take a few days to germinate, the seed-pan should be examined each day, otherwise I find that if the seedlings are left one day longer than they should be, they become drawn. Like all other plants, a good start is half the battle. Keep close to the glass and prick into small pots as soon as they are ready, and at this stage avoid cold draughts.

The Flower Garden.

Hollyhocks.—Where these are grown from seed sown last month, they will now be ready for pricking out, and for this I would advise doing so into small pots in preference to boxes. To have them in bloom in the autumn, they ought to be kept growing steadily in heat for some time yet and potted on when required. They will amply repay any extra care bestowed on them at this stage, as well-grown plants treated as annuals are seldom attacked by the Hollyhock rust.

Cosmos.—The new early flowering varieties of this fine annual are particularly effective dotted among the herbaceous plants. If sown now, pricked into frames and planted out as soon as they are ready, they will bloom continuously from the end of June till frost cuts them down.

Seed-Sowing.—For general purposes most half-hardy annuals may now be sown; but it will be wise to save a pinch of seed of each in case of failure. This may be sown a fortnight hence, when it is just possible that the plants will come in very handy in case of shortage.

Nigella.—Although usually treated as a hardy annual, I prefer to treat this as half-hardy and make two sowings, one now, and another towards the end of the month. The variety *Miss Jekyll* is a great favourite. The flowers are produced in great profusion among the graceful foliage, and where cut flowers are in demand I find it stands cutting splendidly.

Stock Empress Augusta Victoria.—This tall, branching Stock is possibly one of the best lavender kinds in commerce. Last season I saw a long border planted entirely with this variety, and it was a sight not soon to be forgotten. It may be sown now and brought on gently, and in planting out give it at least 15 inches to 18 inches between the plants.

Plants Under Glass.

Coleus.—These free-growing plants, so indispensable for furnishing and decorative purposes, are as popular to-day as ever. Cuttings may now be taken from stock plants and rooted in brisk heat. These will root in about a fortnight. No difficulty need be experienced in obtaining the necessary stock, as those rooted cuttings can be cut over to provide another batch. Seed may also be sown at this time, and if the majority of the seedlings are found to be rather coarse, one is always sure to get one or two that are really worth growing.

Petunia.—This old greenhouse favourite is not now so much in evidence as it ought to be, considering its attractiveness. This cannot, of course, be accounted for by any difficulty in its cultivation, as that, surely, is of the simplest. Cuttings rooted now will make very fine plants in an incredibly short space of time. Seed sown now will also produce very good plants in the autumn.

The Hardy Fruit Garden.

Reducing Flowers of Pears.—As Pears usually show an abnormal crop of flower-buds, I think it is a good practice to go over the trees and reduce these just before they open. This will give those that are left a better chance to set. This, at any rate, might be done with the better varieties, as Pears are usually grown on a south or west wall, with, in some cases, a projecting coping, which has a tendency to keep the trees dry at the root. In such situations it will be well to see that they are fairly moist at the roots, as if allowed to become dry at this stage the flowers would most certainly fail to set. The same remarks apply equally to all wall trees.

Raspberries.—These will now be starting into growth. The tips of the shoots may be somewhat shortened, and recent plantations should be cut back to within 6 inches of the ground.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

BULBS FOR SPRING PLANTING OUTSIDE.

SO much accustomed are gardeners and amateurs to ordering their bulbs and tubers in autumn that many are liable to overlook the fact that it is possible, and even advisable, to obtain some of these in spring for planting at that time. Many of them require to be lifted in late autumn and stored until spring. It is unnecessary to enlarge upon this point, and also to speak of such subjects as *Liliums*, *Galtonias*, *Gladioli*, *Montbretias*, *Begonias*, *Tigridias* and other well-known bulbs frequently planted, and upon whose culture separate articles appear from time to time. The bulbs, corms or tubers mentioned here can still be purchased, and may be planted in March or April.

The Agapanthus, although almost outside our sphere, may be mentioned as good for spring planting in the open. Planted deeply and the foliage left on all the winter as a natural protection, it is hardy even in the South of Scotland. *A. minor mooreanus* is by far the hardiest variety.

Albuca Nelsonii, which has white flowers tinted with red, is hardly ever seen, though in warm climates it may be left out all the winter with but slight protection. Plant 4 inches deep in a sunny place. A few

Alliums are obtainable in spring, and the best of these is probably *A. pedemontanum*, with rose-coloured flowers. It is hardy if planted 2 inches or 3 inches deep. Spring is the best time for planting the magnificent

Alstroemerias. They should never be less than 6 inches or 9 inches deep, and a foot is not too much. The hardiest are *A. aurantiaca*, with its lighter-coloured varieties; *A. chilensis* and its varieties, and *A. psittacina*. Less hardy, but very beautiful, are *A. pelegina* and *A. p. alba*. Those who admire the noble

Belladonna Lily (Amaryllis Belladonna) may be reminded that this is a good time to plant the bulbs from 9 inches to 12 inches deep at the foot of a greenhouse or south wall. It is quite hardy there.

Anemone coronaria may still be planted for late blooms. A delightful little bulb not often met with, and hardy enough to plant now and lift in the autumn, is the blood red *Anomatheca cruenta*. It looks best in half-shade, and should be planted 2 inches deep.

Antholyzas are striking plants, with big plaited leaves and spikes of red and yellow flowers. *A. paniculata* is hardy, and *A. crocosmoides* is nearly so. Plant 6 inches to 9 inches deep in a sunny place. Both flower in the autumn.

The singular *Arisæmas* attract some people, and may be planted now. *Asclepiases* may still be planted, and *A. tuberosa* is the best, although not a great success in the North. Plant 4 inches deep. The charming Mexican Coral Drops (*Bessera elegans*), with scarlet and white flowers, may be grown in light soil if planted 3 inches deep. Lift in the autumn and store in dry sand. The climbing

Boussingaultia baselloides, with small white flowers, does well on warm trellises, planted 6 inches deep. *Bravoa geminiflora* (the Twin Flower) is a beauty with its orange red flowers, and should be planted 3 inches deep in a sunny place and lifted in the autumn.

Chlidanthus fragrans, with sweet-scented, yellow, funnel-shaped flowers, is not quite hardy, but may be planted 3 inches deep and lifted in the autumn. *Commelina cœlestis*, blue, is nearly hardy, and may be planted 3 inches or 4 inches deep in light soil. Though fully open in the evening, the white *Cooperia Drummondii* does well in many places if planted 3 inches deep in a sunny place and lifted in the autumn.

Crinums would require an article to themselves. For permanent planting the best are *C. longifolium* (capense) and its varieties, *C. Powellii* and its varieties. Even *C. Moorei* and *C. yemense* are found hardy by some. Plant the *Crinums* about a foot deep.

Cypellas are good for spring planting. Planted 3 inches deep, *C. Herbertii*, deep yellow, and *Cypella* or *Pohlia platensis*, blue and orange, are charming. Lift in the autumn. *Eucomises* may still be planted; *E. punctata* is the hardiest, standing the winter in light soil in many places. *Geranium atlanticum* is a tuberous Crane's-bill for spring planting, but is hardy.

Incarvilleas, now so popular, may be planted with success. *I. Delavayi*, *I. brevipes* and *I. grandiflora* are the hardiest. *Hymenocallis*es are lovely bulbs to plant in the spring and lift in the autumn. *H. Amancæ*, yellow, and *H. littoralis*, white, may be planted in a sunny place 9 inches deep and protected in the winter. The white, August-flowering *Milla biflora*, half-hardy, does nicely 3 inches deep in a sunny place. The *Pancratiums* are exquisite. The hardiest is *P. illyricum*, but *P. maritimum* is almost hardy. Both have white flowers, and can be planted 9 inches deep. *Rigidella immaculata*, scarlet, may have the same treatment as the *Tigridias*.

Tropæolum tuberosum, which is hardy if planted 8 inches or 9 inches deep, is a beautiful climber with scarlet and yellow flowers. The *Zephyranthuses* are exquisite, *Z. candida* being the hardiest, and if planted 4 inches deep at the foot of a greenhouse wall, will thrive. *Z. Atamasco*, white; *Z. carinata*, rose; and *Z. sulphurea*, yellow and copper, are pretty if lifted and stored in the winter.

S. ARNOTT.

POISONOUS PLANTS.

THE number of vegetable poisons is very large, and a striking feature about them is that they are frequently found in plants which belong largely to natural orders associated with health rather than with death. This is strikingly shown in our own country, as well as in lands more associated with deadly vegetation, and it is a fact which may well call for comment. If, as it is supposed, plants develop strong-smelling or dangerous properties in order to ward off their foes, why do not the harmless members of the order do the same? Why are a few Beans—notably the deadly Calabar—so harmful that it is unsafe to purchase foreign bean-meal, while most of the plants of this large and splendid order of plants are designed for man's use? One or two of the Vetches are other instances. It is difficult to say.

It is true that some harmless plants belonging to poisonous families have rather characteristic, and not very reassuring smells, which seem to connect them with an evil ancestry, but probably this wears off somewhat with cultivation (and

tends to confirm what has been said about harmless plants), just as the poisonous nature of some plants undoubtedly gets less or disappears when they are cultivated. Carrots, Parsley, Fennel, notably Celery, Tomatoes and even Potatoes when green bear out this contention, though the last two belong to a notoriously poisonous order of plants.

G. T.

THE MAKING OF A LAWN FROM SEED.

FOR making a lawn from seed, if the sowing should have to be done in spring-time, the ground, if possible, ought to have been dug over during the winter months and allowed to lie in its rough state until it is time to sow the seeds.

By leaving it lying rough, the frost gets a much better hold, with the result, especially if it is inclined to be heavy soil, that a better and finer seed-bed can be obtained. If the ground is in poor condition, some good, old, rotted stable manure should be lightly dug in; but care must be taken not to dig it in too deeply, as it is essential that the roots of the young plants should reach it as soon as possible if it is to be of any use. The

Preparation of the Seed-Bed in spring should be as follows—at least, I have found it the best: Rake the whole surface to break up any clods and also to remove any stones and rubbish. Make good any hollows by filling them up with soil, and also level any high parts, so as to get the surface as even as possible. When this work has been carried out, tread the whole surface, then rake again, and, after this, roll it until it is quite firm and true. When the rolling has been completed, any unevenness will show, and a final levelling can be done. Before sowing, as the seed-bed is now ready, rake over once more, so as to break up the surface to receive the seed. The

Sowing should be done on a quiet day, and when the ground is dry on the top. Scatter the seed evenly all over and rake lightly in every direction so as to thoroughly bury the seed; but when raking be sure not to rake too heavily, as the seeds only require a light covering. Roll all with a heavy iron roller once, then leave it.

Treatment of Young Grass.—When the seeds have germinated and the young plants are just peeping through, do not on any account roll then; but as soon as the grass is, say, an inch or so high, give a rolling to firm the surface, and mow with a good sharp mower so as not to tear out any of the young plants. Set the mower high enough so as just to cut the ends off the grass. Do not on any account let the grass grow too long, as it is not a crop of hay that is aimed at, but a thick, close carpet of turf, and this cannot be better or more quickly obtained than by keeping it down. I would make a strong point of this last matter in regard to mowing. Care should now be taken not to over-roll, and the roller should not be used when it is raining, a time one very often sees the roller in use. This is a fatal mistake, as the grass, like a human being, must have air. It must surely be only common sense that if the ground is rolled when it is so wet on the top, the roots are being deprived of the air and the young plants are gradually being choked. Never roll even an old lawn when the surface is very wet, and never roll during rain, as I am perfectly satisfied

in my own mind that this has been the ruination of many a good lawn and the means of so many weeds making their appearance where there was once a good, clean carpet of turf.

The foregoing remarks are simply a few of the methods I employ, and, I must say, with excellent results, when I lay down a lawn from seed.

PETER W. LEES.

(Greenkeeper, Mid-Surrey Golf Club.)

SEASONABLE NOTES ON GRAPE VINES.

HEAT, DISBUDDING, AND TYING DOWN SHOOT.

SINCE the weather became milder, the heat under glass has been like summer. Grape-growers always like to experience a period of bright sunshine while the Vines are starting new growth for the year. Shoots forced on by artificial

heat during their early stages, when the weather is generally cloudy, are never strong at first, and, of course, that means loss of time. I have also noticed rather smaller bunches, as the main stem of each bunch and stems emanating from it are shorter. The bunches will be compact enough, but to obtain high-class berries many more of them, regarded as surplus berries, must be cut out.

Sun-heat is, therefore, very precious in the vinery. I quite believe that amateur cultivators lose a lot of sun-heat in the springtime. Of course, they no doubt prevent loss of foliage through scorching, but an expert Grape-grower will husband almost all the sun-heat and do no harm thereby to the leaves, but rather benefit them. The inexperienced cultivator loses the heat through injudicious ventilation. If he opens wide the ventilators—often the front ones as well as those at the top of the house—he causes a current of cold air to pass through the structure, and it chills the warmed leaves. Now, how must the amateur ventilate without causing harm, but with good results? He should open the top ventilators about an inch wide just before the sun shines on the house in the morning. Excessive moisture is thus dried up on the tiny leaves before the sun's rays are strong enough to scorch them. About two hours afterwards open the ventilators another inch, and at noon, if the sun-heat increases, another inch. Front ventilation is neither necessary nor desirable. The heat in the structure may be very high, but it will do good, especially if the path and border are damped once or twice. The atmosphere will become quite moist; it will be what is commonly termed "a growing atmosphere." None of this moisture will lodge on the Vine leaves as long as the top ventilators are open. As the sun's power wanes, the ventilators must be gradually closed; finally, not later than half-past three o'clock in case of a house facing due south.

Saving Fire-Heat.—All this means a saving of fuel and the work attendant on stoking, as the fires must be allowed to burn out each morning as the sun-heat increases, and the pipes must again be warmed as the internal temperature goes down after sunset.

Disbudding.—It is always a pleasure to rub out nice fat buds as long as there are plenty of fatter ones to retain, because one knows that the buds left on the Vines will soon gain extra strength. There are, however, many amateur cultivators

who cannot bring their courage to the point of removing enough of the surplus buds. This has often been proved to me, and, of course, the result is overcrowding right from the beginning. On each spur leave one shoot well placed and, of course, bearing the best bunch of Grapes, as the tiny bunch can readily be seen in the point of a shoot an inch long. The thinning out of the bunches will be a matter to claim attention some weeks later on. All the disbudding must be completed when the shoots are from 1 inch to 2 inches long.

Tying Down the Shoots.—It is wonderful how quickly the shoots grow at this season, and they always point towards the roof glass. The ends of the shoots would be crippled if left for long touching the glass; this should not happen. The young bunches would also be chilled. To prevent any check, commence tying down the shoots just before they reach the glass. Simply bring down the point a few inches; then further in a few days' time, and, when the Vines are flowering, do the final tying to the horizontal bars, as the shoots will stand the strain without snapping off at that stage.

AVON.

SWEET PEA NOTES.

THE present month is of vast importance to all growers of Sweet Peas. The seedlings require careful attention, while the soil which was trenched in the autumn will be greatly benefited by a top-dressing of soot, superphosphate of lime and bone-meal, and a close vigilance must be kept against the ravages of frost, mice and birds; for, should a mishap occur from any of these causes, it is getting almost too late for fresh sowings to be made to produce blooms for exhibition purposes.

Autumn-Sown Plants.—Thus far the winter has been most favourable, and never have I seen plants in a better condition. Of course, it is in March and April that we expect to see the autumn-sown plants "leg along," and the past sunny days have worked their magic charm and vigorous side growths are pushing up well; in fact, all the omens for future success are "set fair." However, it is too early to expect winter to have departed, and sharp frosts must be looked for, so it is necessary to provide protection at night and to give all reasonable care to prevent unnecessary checks occurring. A strong, short-jointed, healthy plant, well able to withstand bad weather when it is planted out, should be the ideal of all growers. To attain this the growing plants will need plenty of space, and on no account must they be allowed to become spindly and drawn, or matted together in a confused mass. See to it that twigs are placed around them before they can topple over, as it is folly to neglect to give them adequate supports. Prevention of trouble is much better than trying to effect a cure, which, in the case of Sweet Peas, is seldom efficacious. An excellent plan, if the grower can give the necessary time and trouble, is to treat every seedling as he would a rooted cutting, *i.e.*, pot it into a 3-inch pot, using good loamy potting soil. I like doing this in early February, and have always found the plants greatly improved thereby. For a few days after repotting I keep them close, but the plants soon get away with renewed vigour. However, by the time these notes are printed it will be rather late for this course to be adopted, yet it

is a plan well worth following, especially if exhibition blooms be the end in view; but in growing for ordinary decorative purposes it is not necessary.

Spring-Raised Plants.—The hardening off of these plants should be gradual, but it is a great mistake to keep them too long in a warm, moist house, and especially if it is not possible to place them within a few inches of the glass; therefore, directly the fourth leaf appears, transfer them to a cold frame, although, of course, common sense must be used in giving them air, as it will not be advisable to expose them fully to the bitterly cold winds so prevalent at this time of the year. Above all things avoid producing a weak, attenuated plant, and such plants are more common from a spring sowing, as they have been grown quickly in a warm, moist atmosphere, whereas those sown in the autumn have braved the chills of winter and altogether are hardier.

Method of Hardening Off.—Perhaps a few words on this will be helpful. The plants, when 3 inches or 4 inches high, should be placed in a cold frame, the lights of which are kept closed for a few days except during bright sunshine at midday, and at night a mat should be placed over the glass. (Some of my readers will rightly say I have often written that Sweet Peas will withstand several degrees of frost. Quite so; yet I do not think it wise to expose tender and oftentimes rare seedlings unnecessarily; hence the foregoing advice.) After ten days of this treatment the plants should be accustomed gradually to harder treatment, avoiding exposure to biting cold winds, and by the beginning of April the lights should be removed altogether, the plants now being sturdy and strong, capable of weathering the adverse climatic conditions they may have to encounter.

Pests.—To frustrate the attacks of birds, mice and slugs, vigilance is the chief weapon. The old-fashioned remedies of cotton for birds and chloride of lime dusted outside the box or frame to keep away mice are effective if applied before the damage is done; but too often these precautions are taken when the crop has been severely mauled.

Soil.—The top-dressing of soil which has previously been trenched is of great importance. This must not, of course, be overdone, but a good dusting of soot, bone-meal and superphosphate should be raked in. I have tested several of the "special manures" that are in commerce, using them instead of the soot, superphosphate and bone-meal, and have found them very good. A fortnight previous to planting I used 20z. of Dobbie's Sweet Pea Manure to every circle of 2 feet diameter, and 20z. of Clay's Fertilizer to every yard in rows, and had excellent results from both. I must mention that good farmyard manure had been well incorporated into the soil during the trenching operations, and the soil had been well pulverised. The texture of the soil has a deal to do with the success or failure of experiments of this kind; but every soil which has been well prepared in the autumn will readily respond to the extra nourishment given by a liberal surface-dressing of soot, bone-meal, &c., or the specially prepared manures for Sweet Peas as advertised in THE GARDEN.

Summer Feeding I will deal with in a future article, as it is an important cultural factor, the misuse of which causes much trouble in bud-dropping, rank, sappy, flowerless growths, and kindred ills.

S. M. CROW.

THE GARDEN.

No. 2209.—VOL. LXXVIII.

MARCH 21, 1914.

NOTES OF THE WEEK.

Protection of Fruit-Buds.—Now is the time when birds do such damage to the buds of the majority of fruit trees and bushes, and means must be taken to ward them off. An occasional spraying with Quassia Extract or any substance that will make the buds unpalatable will to a certain extent stop them.

Planting Forced Bulbs.—A very pleasing effect may sometimes be produced by planting forced bulbs in the wilder parts of the flower garden or shrubbery. These should be planted as soon as possible, as if left until the autumn most of the foliage has died down, and it may just happen that the bulbs are planted too near to a previous plantation.

Transplanting Pentstemons.—The young plants should now be taken from the frames and transplanted in some sheltered spot that has previously been prepared. If some leaf-soil has been forked in, this will not only assist root action, but the plants will lift with much better balls of soil at planting-time. Should severe weather set in, they will require a little protection, say, of Spruce branches.

Sowing Primula sinensis.—To be of any value for autumn decoration, seeds should be sown about the middle of March; and although this Primula requires very little heat during the growing season, it is well to sow the seeds in a temperature of 60°. Prick out the young plants as soon as large enough to handle, keep close for a few days, and water with great care. Clean, well-crooked pots are indispensable, and the soil for future potting may consist of turfy loam and leaf-soil, with plenty of sharp sand to keep the compost from becoming sour.

Saxifraga oppositifolia.—This is one of the most beautiful of early flowering Saxifragas or Rockfoils. A rich mass of its rosy purple flowers on a ledge in the rock garden is very beautiful at the present time. It is one of our rare British flowers, being found in some of the hilly parts of Wales, Scotland and Ireland. There are several beautiful varieties, some with larger flowers or of a deeper colour, as well as a pure white variety, alba. All of the varieties succeed in a well-drained, sunny position, in soil composed of good loam, peat, sand and a few granite chips.

Planting by the Lakeside.—This is the time to make plantations of moisture-loving plants on the banks of streams or ponds. There is no scarcity of plants suitable for the purpose, which may include bold clumps of Iris, of which there are many charming varieties to choose from. *Sparganium angustifolium* may be planted close to the water's edge. *Lythrum*, *Senecio*, *Rodgersia podophylla*, *Aspidistra regalis*, *Gunnera scabra* and *G. manicata* are noble plants, and well suited for the water's

edge. *Myosotis* and *Primula japonica* may be freely planted, and will produce a very pleasing effect, but must be placed well up the bank.

The First Clematis to Flower.—*Clematis calycina* is the first of the genus to flower, often commencing in January, and for this reason it should be grown more than it is. The pendulous flowers, which are borne in the leaf-axil, are 1½ inches in diameter, the petaloid sepals being of a yellowish white, faintly spotted on the inside with reddish purple; and although the flowers

planted out carefully, little damage need be done to the roots. By adopting this method one has a reasonable chance of getting them into bloom with the other bedding plants.

Pruning Roses.—The majority of Roses may now be pruned. Notwithstanding the great advance made in Rose-growing during the past year or two, it is surprising to see the number who still persist in pruning their Roses as one would a hedge, all shoots being cut over, big and little alike. Expert Rose-growers know the peculiarities of each variety, and will prune accordingly. But for those having only a miscellaneous collection, the following rule may be followed: Cut clean away all weak and sickly shoots, leaving only matured shoots of moderate thickness, and these may be cut back to within 4 inches to 6 inches of the base.

Dividing Aspidistras.—Few plants are more useful for house decoration than the Aspidistras, especially where gas is used. Both *A. lurida* and its variegated form are equally hardy, and with a little attention will flourish in out-of-the-way positions, where most other plants would quickly collapse. The present is a suitable time for the propagation of these useful plants. Take the old plants that are to be divided and pull them to pieces with one or more leaves on, according to the number of plants it is desired to make, and then pot them up in a mixture of fibrous loam, leaf-soil and sand.

The New Director at Wisley.—Just as our last issue had gone to press we received a notification from the Royal Horticultural Society to the effect that Professor Keeble, F.R.S., of University College, Reading, had been appointed Director of the gardens at Wisley. It will be remembered that at the annual general meeting of the Fellows held in February last the Council were empowered to spend some of the surplus funds for the purpose of developing the gardens on scientific lines. We understand that Professor Keeble's duties will include the general guidance and supervision of the trials, teaching and research. It is pleasing to learn that Mr. F. J. Chittenden will remain in charge of the educational section, where he has already done a great deal of good work, and that Mr. S. T. Wright, the superintendent, will still supervise the practical work. We wish Professor Keeble every success in his new sphere, and hope that he will always remember that practical horticulture is of far greater importance to the Fellows of the society than purely scientific research, which is already being carried out in many other directions. There is a danger of unnecessary overlapping in many of the experiments that are being conducted in different establishments.

PROFESSOR KEEBLE, THE NEW DIRECTOR AT THE ROYAL HORTICULTURAL SOCIETY'S GARDENS.

may not be termed showy, they are, nevertheless, distinctly pretty against the handsome dark bronzy green, finely cut foliage. Although hardy, it should be given a south wall, as this enables the wood to get thoroughly ripened, which is essential for a good display of flowers.

Treatment of Gladioli.—There seems to be a great diversity of opinion as to the treatment of these stately flowers. Some advocate potting the bulbs, and, where space is plentiful, this method has much to commend it. Others, again, plant the bulbs where they are to flower, and in early districts this would seem to be the better method of the two. But in cold and late districts it is preferable to place the bulbs in ordinary cutting-boxes now, and stand them either in cold frames or in a cool house. If well hardened off and

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Borders of Lavender and Pinks.—In this damp climate the common and Dutch Lavenders are very apt to die off in big pieces in the spring. To avoid bare spots we put in single Pinks from cuttings all around the plants, hoping they would grow up and through the grey bushes. The result of the experiment in its third year can be seen in the accompanying picture. There are three shades of pink in the flowers and three shades of grey, including the stone paving, so there is no monotony in the scheme. The Pinks lasted in bloom more than six weeks last summer, and filled the small garden with fragrance; and the Lavender, we find, gives out its scent even in winter.—ROSA TANGYE, *Westmere, Edgbaston.*

Tall Antirrhinums.—As I consider the better varieties of these plants among the best of

able article on page 131 and page 132? I am sure it is known to very many of your readers. It might appropriately be described as a bicolor, but the colours (pale rose with white) are so soft and blend so well that it is a general favourite.—F. R. H. S.

Lachenalias as Room Plants.—Few take the trouble to grow these bulbs well, and the results, in consequence, are poor, and then they are not appreciated. I try to do what I can for them, and I am rewarded. I had a beautiful pan of *L. Nelsonii* in my study for no less than twenty-two days last February. I live in the room every day, and at night, with the oil lamp and fire combined, it gets pretty warm (of course, no gas). Is there any Hyacinth, Tulip, Daffodil or Narcissus that will go on so long under like conditions? *Nelsonii* is good, but give me the rich deep orange yellows of Rose Barton and the larger-flowered and more open bells of St. Patrick. This latter, coupled with Shiner and John Geoghegan, I put at the very top of Sir Frederick Moore's striking

white eye or centre. Both are well worth growing. They are equally floriferous, not only under pot culture, but when bedded out during the summer months, under which conditions I have met with them in several instances within the last two or three years.—H. P.

Myosotidium nobile Flowering in Scotland.—There is a nice specimen of this rare plant, which was sent from a Cornish garden last autumn, in flower here at present. It subsequently lost all its leaves, but these were renewed during the winter. It is a lovely flower, and one would be glad to know if it seeds freely from self-fertilised seeds, or if these are fertile if and when produced. I would like to see it prospering in a warm corner in the open. Has anyone in the North, in the Rhyns of Galloway, for instance, or in the Black Isle, succeeded with it in the open? Another of our treasures, a Primrose of a peculiarly nice shade of green, found by Lady Grisell Baillie-Hamilton, is also in flower. The original plant prospered so well at one time that plants were given to several gardens, leaving a nice lot for this garden. But they suddenly gave way, and I could with difficulty save only three pieces from the general doom, and, strange to say, every plant of those dispersed went the same way. It was equally vexatious to lose at the same time a small piece of a double green the late Peter Barr favoured me with.—R. P. BROTHERSTON, *Tynninghame, Prestonkirk.*

Miniature Hyacinths.—Reading the note on miniature Hyacinths by the Rev. J. Jacob on page 114 of March 7 issue, it seemed very strange that he accurately describes another variety under the name of Orange Boven, namely, the so-called yellow Roman Hyacinth. This variety is seemingly a true Roman, being thin, tall and stiff of stem, with medium-sized bells lightly and sparsely arranged. The flowers are delicately perfumed, not so strong as the white Roman, and for cut purposes even better and far preferable to the general run of miniatures, which sometimes, at least, are quite nasty things, both as Hyacinths and flowers. The yellow Roman does not force quite so early as the white variety, and makes a much prettier pot plant. The colour, again, is not yellow, neither is it orange, but there are shades of both. Yet another Hyacinth that on its merits deserves a note of recommendation is a French variety called Couleur de Chair. It forces rather easier than the miniature forms, and is a much better pot plant. It is very good as a February flower, and of a delicately shaded rose colour, rather too deep for flesh, as the name would suggest. Grown three or four bulbs in a pot, it makes a charming and welcome effect during a month when flowers are greatly needed, especially of that colour. A word concerning Tulips may not be out of place. How many are there who, having to maintain a wealth of cut flowers, think of forcing varieties of Darwins! Some of these, by reason of the long stems and large leaves, are very suitable for cutting, and look exceedingly effective, the colours being of varied and contrasting hues. A few worth mentioning are Rev. Ewbank, Mrs. Farncombe Sanders (brilliantly beautiful), Mme. Krelage, Glory, Pride of Haarlem, Fra Angelico, Harry Veitch and Orion. One of the sweetest Tulips in cultivation, and suitable to be grown in pots and for gentle forcing, is Orange King, a May-flowering type and exquisitely scented. The rich colour alone is sufficient to recommend it.—H. R., *Twickel Castle Gardens, Holland*

BORDERS OF THE COMMON LAVENDER AND PINKS IN A READER'S GARDEN AT EDGBASTON, BIRMINGHAM.

hardy plants, I was much interested to read the article by Mr. Brotherston on page 131 of your issue of March 14. He mentions with approval some plants having spikes 7 feet high, and seems to have a contempt for those of normal size! This is rather strange, bearing in mind that the intermediate section, growing about eighteen inches, is just now the most popular and contains some of the best varieties. Surely these and the ordinary tall varieties are incomparably more beautiful and more useful than such monstrosities as your contributor mentions. I find Antirrhinums can be grown as hardy annuals with very fair success, the seeds being sown in a glass-covered box in March, without artificial heat. Good loamy soil should be used to ensure quick growth. Some plants I raised in this way last season bloomed, in poor soil, for quite two months, and made fine, large, branching plants.—G. L. J.

—Why does Mr. Brotherston omit Antirrhinum Cottage Maid in his comprehensive and

creations. August potting, light, rich, well-drained soil, air and a moderate temperature and thorough ripening are the main factors in successful culture.—JOSEPH JACOB.

The Shrubby Browallias.—There is a great tendency to regard all Browallias as annuals; indeed, the shrubby-growing *B. speciosa* major was recently referred to in THE GARDEN as an annual. Though seed is readily obtainable and seedlings grow away readily, there is no need to depend solely upon this mode of increase, as cuttings root without difficulty, and plants so obtained will flower in quite a small state. As a decorative plant *B. speciosa* major well merits all that your correspondent says in its favour, for it is almost continuous blooming. A second species, *B. viscosa*, which is also described in some horticultural works as an annual, is of as pronounced a shrubby character as the other. From *B. speciosa* major this species differs in the flowers being smaller, and in colour a deep blue with a

Peat Moss Manure.—In the most interesting letters that have appeared in the pages of THE GARDEN on this subject, all your correspondents seem to have overlooked one great fault in its use as manure, viz., the quantity of weeds that invariably follow wherever it is dug into the ground; at least, that is my experience. At one time it was used in the stables here. Mixed with the straw manure I found it very good for nearly all green crops, except for the trouble of the weeds, especially a variety of Sow Thistle, which no amount of heating or fermenting the manure-heap seemed to destroy the vitality of its seeds.—H. REYNOLDS, *Scratby Hall, Great Yarmouth.*

Lime in the Garden.—I have been very much interested in reading in THE GARDEN of February 28, page 111, an article by Professor Houston on the uses of lime in gardens. The last paragraph was, however, a great surprise to me, as he states there that lime must not be used in planting Potatoes. My experience is to the contrary. Last year my gardener, when planting Potatoes in drills 9 yards long, spread in each 1½ st. of freshly ground lime, and then covered it over with soil. The Potatoes were all sprouted at the time. On lifting them in the autumn the average yield was 5st. to each drill. The quality of the Potatoes has been exceptionally fine. I have constantly remarked during the winter how good they were. I have had lime recommended for dressing the lawns in the spring. Can any gardening friends tell me if they have tried it, and with what result, and also what quantity should be applied?—J. D.

Sparrows Eating Yellow Crocuses.—In your issue for March 7, page 113, there is a note on the damage done by sparrows to yellow Crocuses, and it is remarked that other colours are left alone. I have seen it suggested that some sweet juice is found by the birds in the petals and stems of the flowers; but this is hardly probable, as the behaviour of sparrows when tearing the Crocuses to pieces suggests annoyance rather than pleasure. Nor are Crocuses the only flowers injured in this manner. Polyanthus often suffer severely, but the pale shades are never attacked so ferociously as the bright colours or those rendered conspicuous by a dark ring. According to my experience, the reason is to be found in the effect of bright yellow upon the birds. Those who have studied the subject of colour will know that red inspires fear in birds and animals, while yellow appears attractive, but often arouses excitement amounting to irritation. I have known a brood of chickens thrown into a state of panic by the sight of a red object, while they pecked with excited curiosity at a yellow one. It is puzzling to say why birds should molest some yellow flowers while others, equally bright, are left alone; but some plants, such as Winter Aconites, probably possess an acrid juice distasteful to birds, while smaller subjects, such as Tulips, are more difficult to injure than those nearer the ground. Spring flowers, naturally, suffer the most, because later in the year the greater predominance of colour in the landscape would prevent a single species from attracting much attention. Birds, too, are in a far more excitable state in the spring, and weather conditions may explain why more damage is done one year than another. It is strange that some gardens should suffer more than others, but the position of the flowers may in some cases keep the birds from attacking them. I myself have noticed that Crocuses when planted in

small clumps are more severely injured than those planted in large sheets; but the whole subject is full of interest, and possibly some of your readers can throw more light upon it.—(Miss) E. A. PATCH, *Aldbourne, Wilts.*

Saxifraga burseriana and its Varieties.—With further reference to *Saxifraga burseriana*, "Alpinist's" note on page 114 of March 7 issue raises an interesting question, which, I think, it is most desirable should be discussed and answered authoritatively before the forthcoming Saxifrage Conference. I refer to the question of whether the Saxifrages commercially listed and sold as distinct varieties of *S. burseriana* are, in fact, distinct. I think that I can solve one at least of "Alpinist's" doubts. At the present moment there is in flower upon a moraine in my garden a plant of *S. b. Gloria*, one flower of which can just, and only just, be covered by a half-crown piece. This plant has not been disbudded. It is true that it is a very small and youthful plant, and has thrown a single flower-stem only, but upon that stem it has at least two, and possibly three, flowers. Among the thousands of the finest possible examples of *S. burseriana* type which I have examined, I have never seen any single flower making any approach to such a bloom of *S. b. Gloria* in point of size. I think that "Alpinist" may be basing his judgment, as I have sometimes done, upon specimens purporting to be *S. b. Gloria*, *S. b. major* and so forth, which in reality are nothing of the kind. An important point to be borne in mind is that *S. b. Gloria* does not come true from seed. Now, I fear it cannot be disputed that seedlings of *S. b. Gloria* are frequently sent out as *S. b. Gloria* itself. As at present advised, I am unable to find any definite differentiating feature in the so-called variety *S. b. major*. My own *burserianas* (type) are in every way superior to a batch of *S. b. major*, which I was misguided enough to purchase at a price considerably higher than the current price of the type; and I am decidedly of opinion that the ever-increasing multiplicity of names is, from every botanical and horticultural point of view, unjustifiable. But in the case of *S. b. minor* there is no longer the least doubt that the matter is different. *S. b. minor* is at least a fortnight later than the type in flowering. Its habit is altogether distinct, being compact and cushion-like, while its flowers are very much smaller, and borne upon shorter and more slender stems. It has been suggested to me that there is a difference in the number of anthers in these varieties; but this is not so, since in all forms the number is normally ten. I must not trespass further upon your space to go into the questions aroused by *S. tridentata* and so forth; but I should, in conclusion, like to draw the attention of your readers to a delightful novelty which I saw upon Mr. Tucker's stand at the meeting of the Royal Horticultural Society on the 24th ult. This form is named *S. crenata*. As its name implies, it has crenated or notched edges, and is both dainty and altogether distinct from any other form.—RAYMOND E. NEGUS, *The Lawn, Walton-on-Thames.*

FORTHCOMING EVENTS.

March 24.—Royal Horticultural Society's Exhibition: Lecture at 3 p.m. on "Pruning Shrubs," by Mr. E. Beckett, V.M.H.

March 26.—Manchester and North of England Orchid Society's Meeting. Royal Botanic Society's Meeting.

PRUNING ROSES.

WHY IT IS NECESSARY.

PROBABLY there is no subject that has been so much discussed and written upon as pruning Roses, and yet, judging from letters received, there are numbers of readers quite at a loss to understand its mysteries.

And yet there should be no mystery, for the most casual observer of our wild Roses will see that Nature has endowed them with remarkable recuperative powers, so that when old growths have exhausted themselves by abundant blooming, there are other and younger growths springing up from the base to carry on the decorative work. It is the same with our modern Roses. Let anyone examine a well-grown bush or standard, and he will observe several fine shoots that have emerged close to the base of the plant, and which seem to appeal to us to cut away some of the older growths to afford them light and air wherein they may develop.

What to Cut Away.—As to how much one should prune back a certain Rose only needs a little observation to determine. Surely, where Nature has given a Rose, such as Hugh Dickson, the power to send up a growth from 7 feet to 12 feet in height, it would be madness to cut such a growth as close down as one would a Rose of the type, say, of General Macarthur. I would, therefore, while giving some general hints, counsel readers to observe for themselves, and, above all things, if the work of pruning must be relegated to that much-abused man, the "jobbing gardener," see that the plants are not all shorn alike, as if some sheep-shearer had been at work.

An instance of what I might term "unorthodox" pruning came under my notice a year or two ago. A large collection of garden Roses, planted two years previously, had made splendid growth, and as the winter was a mild one, the gardener determined he would not prune severely. All the previous year's growths were retained almost full length, and merely old wood cut out. The result was a glorious mass of bloom. The evil of this practice would be that the plants would not produce such good basal growths as they would have done if pruned more severely, so that another year the plants would be somewhat unshapely, unless care were taken during the summer to prune back some of the growths. I am quite persuaded that if we were sure of our winters not harming the wood, many of our glorious Tea and Hybrid Tea Roses could be allowed to grow into quite huge bushes, feeding them generously, of course, so that the extra demands upon the plants' resources could be satisfied. It seems like a fairy tale to read of plants of Papa Gontier and such-like Roses growing into bushes larger than Lilacs in the sunny Riviera, where they may be seen lining railway tracks, overtopping fences, &c. I have seen something similar in sunny Devonshire, so that all who are fortunate enough to dwell in such salubrious districts must not treat their Roses as becomes necessary to those who dwell in a colder part, for it is absolutely fatal to successful Rose culture to attempt to obtain blooms from growths that have had their pith browned by frost. I believe the retention of such wood has caused many disappointments. I think it was at Ulverston that about two years ago an amateur exhibited some of the grandest blooms of Mrs. Foley Hobbs that have ever been seen, and they were cut from unpruned bushes growing near

the sea among Apple bushes. The Roses had been highly fed with chemical manures, and there they were, a feast for the eyes.

We frequently, in cottage gardens, meet with most remarkable specimens of La France and other Roses that have had very little pruning, specimens we have all envied, which have left us pondering that we who make Rose-growing our profession have much to learn, even from the humble cottager. It is much a case of environment. Notice how a plant of Marie van Houtte will attain to a height of some 20 feet when upon a congenial wall; whereas the same variety in the open would need to be hard pruned if the winter happened to be severe. Walls for such Roses should be reserved, wherever possible, and I hope soon to see Roses of the type of Lyon, Rayon d'Or and Willowmere luxuriating thereon, for I am inclined to think the beautiful tribe, the Pernetianas, are peculiarly adapted to such a purpose.

Spring Frosts.—Unfortunately for us, there is always a big "but" to remember. What a glorious show of Roses we might have "but" for the blighting May frosts! How promising the growths are now breaking; it seems a crime to prune them away, and yet, if retained, we might have all spoilt by the cruel frosts of spring. This year, especially, we must harden our hearts, for I think I never saw the Roses so forward as they are now, the beginning of March. We know only too well the result of May frosts upon forward growths, namely, deformed, green-centred blooms, and it is wisest to prune to dormant eyes Roses that are growing in exposed districts. Every reader must determine what his object is in growing Roses—is it for exhibition or for garden display—as from his determination in this respect must his pruning be regulated.

The Grower for Exhibition must prune severely. One cannot, as a rule, have quality and quantity. Many growers of garden or decorative Roses find it best to plant more closely together, so that they may have both, and in a great measure they succeed; and, of course, the Roses can be as they should be, replanted every three or four years.

The Method of Pruning should be to cut out all old worn-out growths; then completely cut out soft, pithy shoots, produced very late in the season. This will leave us with two, three, four, and perhaps more good sound growths—growths that have more solid wood than pith, and it is from such growths our best Roses come. Amateurs are terribly afraid to thin out the shoots. One often meets with standard Roses whose centres are crowded with innumerable small shoots, quite useless, and which, if allowed to remain, form a splendid hiding-place for the numerous foes of the Rose.

DANECROFT.

(To be continued.)

A LITTLE-KNOWN SHRUB FOR A SHELTERED POSITION.

CYRILLA RACEMIFLORA.

THIS interesting shrub is a native of North Carolina and Florida, and is also said to occur in the West Indies. Though first introduced as long ago as 1765, this Cyrilla is a rare plant in gardens. This is no doubt due to the fact that it is on the borderland of hardiness, requiring in the London district to be grown in a sheltered position, though no doubt in company with other rather tender subjects it will flourish in the gardens of the South and West. Growing wild, *Cyrilla racemiflora* is said

FLOWERING SPRAY OF CYRILLA RACEMIFLORA, A RARE SHRUB IN GARDENS.

to be a small tree, but at Kew it forms a small, evergreen bush, bearing in August and September slender, cylindrical racemes of small white flowers 3 inches or 4 inches long. The leaves suggest those of a Privet bush, and the inflorescences those of a shrubby *Veronica*. This species is sometimes referred to as *C. parviflora*, it is indeed an attractive shrub when in flower, and is worthy of a place in any favoured garden where uncommon shrubs are cherished. *Cyrrillas* flourish in light, sandy loam, peat and leaf-mould. They are propagated by cuttings made of the semi-ripe shoots in late summer and inserted in a propagating-frame with slight bottom-heat.

SHRUBS FOR PRESENT PLANTING.

ALTHOUGH most people like to cease work connected with the transplanting of shrubs early in March, in order that there may be no disturbing element to mar the effect of spring flowers in shrubbery or pleasure ground, there is no reason why, under certain conditions, the work should not be prolonged until early April; while with some kinds of evergreens it is even wise to delay it until the end of April. When people change houses in March, it is often a case of conducting planting operations late in the month or leaving their gardens in an unfurnished state until autumn. Moreover, it is their only chance of transferring special or favourite shrubs from one garden to another; and, providing the work is conducted in a careful manner, there is no cause to fear that the results will be unsatisfactory. It is necessary, however, to observe more than ordinary care at this season in the performance of the work, for it must be remembered that both roots and shoots are in active growth, and any considerable exposure of the roots would be harmful.

Transplanting.—The first point to consider is the preparation of the new sites, and these, together with a plan of the planting or arrangement of the shrubs, should be ready before the plants are disturbed. Then on a mild and, for preference, a moist day dig up the shrubs and transfer them without delay to their new quarters. If they have to travel any distance, be careful to protect the roots with damp canvas or other material; even when they are only likely to be exposed for a short period it is wise to cover them up with canvas. Whenever a ball of soil can be moved with the roots it is wise to do so. If some of the plants show signs of growth and the buds of others are not pushing, move the more advanced ones first, for the earlier they are settled the better. When planting, it is a good plan to place part of the soil about the roots, then give a good watering, allowing the water to thoroughly soak both the soil and the roots. The remaining soil may then be filled in. Should the weather be dry and sunny, it will be found advantageous to syringe the bushes once or twice a day for a week or two. This will add to the labour, but in the end it will be found to be time well spent. When shrubs have to be moved a considerable distance, which means a journey by train or road, additional care is needed to make sure that the roots shall not become dry. Take up the plants carefully, and, if balls of soil are attached to the roots, wrap each one round

separately with damp hay, afterwards sewing it up in damp canvas or matting; but if the plants are removed without soil, a number of them may be made into a bundle. First lay a strong bast mat on the ground, over it place a little damp hay, then, after tying the top of each shrub into the smallest possible compass, lay the plants on the mat one above another, placing a little damp hay round the roots and a little among the branches. When a sufficient number have been placed together, lay another mat over them and sew them into a close bundle. On arrival at the new garden, unpack them carefully, and give the roots a good watering, if they appear in the least dry, before they are planted. When it is known that deciduous shrubs may have to be moved late in March, it is a good plan to lift them and lay them in again in a shaded position with a northerly aspect. This will have the effect of checking growth and making the buds at least a fortnight later in breaking into growth. When bushes are large and dense, it is a good plan to remove a few branches when the transplanting is in progress, which will relieve the injured roots of a portion of their work. Where evergreens are concerned, it is also wise to remove a certain amount of branch growth at any period when transplanting is conducted, and if branches cannot well be spared, then the leaf surface may be reduced by stripping off a quarter or even half of the leaves.

The transplanting of small shrubs at this period is not a troublesome business, and a great deal of transplanting in nurseries is carried on during April. When, however, it is possible to transplant at an earlier date, it is wise to do so, for, the earlier the plants are established, the less trouble are they in the event of the occurrence of a dry spring or summer. Newly planted shrubs, and particularly those which have been disturbed in March, are benefited by being provided with a mulch of decayed manure or leaves towards the end of April or early May. This will have a good deal of watering, in addition to keeping the soil cool about the roots.

Roses are, perhaps, as difficult as anything to deal with at this period, more particularly the climbing kinds, for growth has been going on for some time. The best plan to adopt is to cut them well back as soon as they are planted. In the case of climbers the flowers will be sacrificed, but it is doubtful whether they would mature in any case, and, by this severe pruning, the prospects of good growth for the succeeding year are greatly increased.

Regarding deciduous and evergreen shrubs, there are few kinds which cannot be dealt with now; while Magnolias, Portugal Laurels, Evergreen Oaks, Hollies, Bamboos and a few other subjects may be conveniently left until the end of April. At no time must the roots of shrubs be allowed to become dry, and even though the roots are out of the soil for a short time only, they should be covered over with mats in the manner above described.

D.

HARDY HEATHS.

(Continued from page 131.)

VISITORS to the Scottish Highlands who have perhaps been expending large sums of money in importing to their Southern homes huge quantities of stone and other ingredients for the construction of rock gardens cannot fail to be impressed by the many ideal and natural positions to be seen almost everywhere on the slopes of the Grampians. The boulder-strewn surface provides all the necessary material close at hand, and the clear and bracing atmosphere should, one would think, provide the most congenial conditions that could be found out of Switzerland. In the hands of Nature the contour of these positions is so fashioned that the services of a landscape gardener or artist would be considered superfluous. In a lovely

trickling over the crest of the hill, apparently midway between earth and sky, and gathering force as it descends to join the river below. It passes within 50 yards of the house, and besides supplying the water for domestic purposes, will be utilised in forming water and bog gardens. Near the house and towards this stream the ground is fairly level for a bit; then it falls abruptly to a practically level space on the side of the stream. The latter will be the site of a water and bog garden, surrounding which and rising out of it will be the rock garden, and beyond we hope to construct our Heath garden.

The natural Heather at this point will be all cleared away and the soil enriched to admit of us giving a fair start to the more select varieties of hardy Heath that we propose planting. These will be disposed in large patches, finding suitable pockets among the natural boulders that are freely distributed over the whole area. Additional

AN EFFECTIVE GROUPING OF THE WHITE CORNISH HEATH (ERICA VAGANS ALBA).

glen among the Grampian Hills, and just on the fringe of the domain of "King Grouse," a summer residence, which to all appearance would suggest to the stranger a shooting lodge, has been erected.

The situation, on a slight eminence, and formerly the site of a small Highland clachan long since fallen into decay, has been selected in order to command some of the prettiest views to be found in this wild and rugged country. Away to the south, as far as the eye can reach, the hills on each side of the valley gradually diminish in size until they emerge on the large and fertile valley below. To the north and east the hills rise abruptly, until their distant peaks appear snow-capped and uninviting, unless to the hardy mountaineer; but during the autumn the whole is transformed into a sea of purple, relieved on some of the lower stretches by small plantations of Birch.

Looking eastwards and upwards, a mountain stream can be discerned in the distance coming

stones, if wanted, can be easily procured by sliding or rolling them down from a higher level. Some slight shelter from the biting winds that frequently sweep down the glen will be afforded by means of a belt of Mountain Pine to the north and east of the site, and the formation of our Heath garden will be so arranged that the artificial plantation will merge and lose itself in the expanse of the native plant. With the aid of some turf, cut and stacked with a plentiful mixture of manure, we possess all that is necessary to ensure a suitable compost in the event of the natural element being insufficient. Like many of the alpine plants which live on a very meagre diet in their native hills, yet take kindly enough to treatment in a rich soil, the Heaths, when transported from their homes, appreciate a much more liberal fare in the way of good soil and manure than one would expect from the conditions in which they are found growing naturally.

Possessing such a suitable position and with an unlimited boundary, a full collection represented by large breadths of each will be planted, and no formal arrangement will be attempted. A few flat stones at convenient distances will be laid in order to form comfortable pathways throughout the plantation. Beginning our planting nearest the rockery, the choicest of the dwarf varieties will occupy suitable pockets there, and we anticipate an unqualified success with such varieties as *Erica vulgaris alba*, *E. v. a. flore pleno*, *E. v. a. minor*, *E. v. aurea*, *E. v. argentea*, *E. v. cuprea*, *E. v. decumbens alba*, *E. v. pilosa* and *E. v.*

ASTER DISEASE: A PREVENTIVE.

PROBABLY a large number of gardeners have asked themselves of late, or will do so during the next few weeks: "Is it any use sowing Asters?" There is not the craze for them that there is for Sweet Peas, but Asters and Stocks are our most popular half-hardy annuals, and are looked upon as indispensable in most gardens, so that many may be glad to

as Carrots or Onions are sown; the resulting plants are neither transplanted nor thinned out, only kept clean, and on good soils the blooms seem in no way inferior to those from plants reared under glass, but flower somewhat later. This is one drawback to the method, as it is imprudent to sow outside until more genial weather prevails; but in the South it should not make much difference, while in colder districts the protection of a Violet frame or hand-lights is advisable until the seedlings are up. A fine tilth is desirable, as good Aster seed is not cheap, and if the bed is at all rough a percentage of the seed will be wasted; but if a

dry autumn occurs, a large quantity of Aster seed can often be gathered, which has its advantages when spring recurs. The flowering period is later, and forms a succession to the plants bedded out, or the survivors of them.

Why Aster plants treated in this manner are immune from disease I do not know, and can only state it as a preventive I have proved during the last three summers, which have been a severe test so far as climatic conditions are concerned. During this time I have not observed a single plant die of this disease, though Asters did badly during the cold, dry summer of last year.

East Yorkshire.

MICHAELMAS DAISIES FOR CONSERVATORY DECORATION.

NOW is the time to pot up these charming plants to introduce into the conservatory or greenhouse or the hall in September and October, where they would be highly appreciated as a novelty and for their graceful habit at a time when colour is wanted and families are at home

for the shooting season. As they are protected from winds and rain, the blossoms expand to their full beauty and can be introduced in succession, reserves being kept in a north house or orchard-house.

Single crowns should be selected and potted into 7-inch or 9-inch pots in good loam with a little well-rotted manure and sand. When potted, shade for a few days until the plants have recovered from the shift; then stand them out of doors on an ash bottom to prevent worms entering the pots, or stand the pots in pans. When they are 1 foot high, place a suitable stick to the plants and tie them loosely; and from time to time turn the pots round to get a regular set of side shoots, and see that the watering is attended to regularly.

When the buds form, a little weak liquid manure will be helpful, as by that time the roots have exhausted the soil. By using only single shoots, the plants assume a pyramidal or conical shape and the natural habit is developed, in preference to that crowded, bundled appearance so often seen in the open border, and the graceful pendent shoots of the *ericoides* section are seen to advantage. The following can be recommended for this purpose:

Large-Flowered.—Climax, light blue, 5 feet; Lil Fardell, silvery rose, early, 4 feet; Robert Parker, dark lavender, 4 feet; Nancy, pale blue,

CROCUSES NATURALISED UNDER TREES ON GRASSY MOUNDS.

pygmæa; *E. mediterranea alba*, *E. m. glauca*, *E. m. nana* and *E. m. stricta*; *E. Tetralix alba*, *E. T. a. major*, *E. T. molle*, *E. T. pallida* and *E. T. præcox*; *E. cinerea alba*, *E. c. a. major*, *E. c. atrosanguinea*, *E. c. coccinea*, *E. c. purpurea*, *E. c. rosea* and *E. c. rubra*; *E. Veitchii*, *E. Stuartii*, *E. Lawsonii*, *E. mackayana* and many others. Having disposed of these dwarf-growing and rare varieties on the boundary lines of the rockery in modest quantities, we shall extend our operations on larger and bolder lines, using freely of such bright varieties as *E. vulgaris Alportii*, *E. v. Hammondii* and *E. v. Searlii*; *E. carnea* or *herbacea* and *E. h. alba*; the various varieties of the Cornish Heath, the Dorset Heath and some of the taller varieties, embracing *E. arborea*, *E. multiflora*, *E. codonodes*, *E. stricta* and *E. mediterranea*; and we must not omit large breadths of the midsummer-flowering varieties, *E. australis* and *E. mediterranea multiflora*. The spring-flowering varieties may have their flowering season considerably retarded owing to the high altitude and consequent long presence of snow, so that on the approach of favourable weather we may expect to have one long continuance of bloom.

Glamis.

THOMAS WILSON.

(To be continued.)

try a simple remedy for the insidious black leg which carries off so many of them. In my own garden for a long time it was simply a gamble to make a sowing of Aster seed, for, in spite of every care, they would die like flies from the time they were pricked off to the flowering stage, this latter occurrence being most exasperating. A neighbour lost over three thousand plants one season just before they were bedded out, and I often meditated giving them up, but never did, for the improved varieties of late years are most fascinating, with their long stalks and soft colours, either in the garden or as cut flowers.

Soil fumigation, spraying, keeping very dry, growing with or without manure, in various kinds of soil, were all tried as infallible remedies, until I began to think there were as many remedies for this as for neuralgia, and that they were about as effective. A chance visit to a market garden in the Midlands provided me with the remedy I had been seeking, and the proprietor, who grew Asters in quantity for marketing as cut flowers, vouched for its success after seven years' trial, and I have tried it for the last three years with equally good results.

It is very simple, and merely consists of treating the Aster as a hardy annual and sowing directly into the open ground, practically in the same manner

4 feet; Mrs. Rayner, rich carmine, 4 feet; Daisy Peters, white, 4 feet; Rapture, pale rose, 5 feet; Finchley White, 4 feet.

Medium-Sized Blooms.—St. Egwin, bright pink, 3 feet; Mrs. J. G. Day, rosy pink, 3½ feet; Royalty, rose pink, 2 feet; Saturn, amethyst blue, 5 feet; cordifolius Daydream, white, 4 feet; c. elegans, rosy lavender, 4 feet.

Ericoides (Heath) Section.—Amity, white, pretty habit, 2 feet; Clio, bluish flowers, 3 feet; Harmony, pale blush, 3 feet; Hon. Edith Gibbs, pale blush, 5 feet; Laceus, white, late, 5 feet.

GEORGE BUNYARD, V.M.H.

WALL GARDENS AND WALL PLANTS.

IN Nature we see that the most charming and delicate plants grow between stones; moraines, rocks, pierriers (the stone piles or heaps that fall from the mountains) and walls are the best frames for the finest of the alpine plants. I never saw anything more beautiful than the carpets of *Viola cenisia*, *V. Comolii* or *V. nummulariæfolia* in the pierriers of the Alps, or of *Androsace glacialis*, *Eritrichium nanum* and *Saxifraga aphylla* on the high paths, and the poorer the soil the better the plants flower. In the old walls of this country, along the lakes, and on the borders of the most sunny roads you can see in thousands the noble flowers of the Red Valerian (*Centranthus ruber*), the pendulous flowers of *Corydalis lutea*, *Antirrhinum majus*, *A. Asarina*, *Cerastium*, *Dianthus* and many others. These walls are exposed to the full sun the whole year, and are naturally adorned with flowers. The reason why is because the stone is a retainer of the atmospheric moisture. Like a swamp, the stone retains moisture, and returns it by degrees to the air or to the roots of the plants which grow in it. Yet, on the other hand, in those countries where humidity is a nuisance, the stones are precious, because they drain the soil and absorb the water in their multitudinous canals.

In England particularly the walls are excellent for cultivating the most precious and tender of the alpinæ, especially such as *Androsace* and *Eritrichium*. My first wall garden was built in my formal garden at Plainpalais (Geneva) in 1885. There I had some beautiful plants, and I flowered very well *Campanula Raineri*, *C. excisa*, *C. petræa*, *C. Zoysii*, *Androsace Helvetia*, *Saxifraga media*, *S. aretioides*, *S. Vandellii*, *S. diapiensoides*, *S. valdensis*, *Eritrichium nanum*, *Phyteuma comosum*, *P. humile* and many others. Here at Floraire I made a new wall some ten years ago, and it is now in its beauty. The wall is 84 feet long, 6 feet wide and 5 feet high. It is an isolated construction, filled inside with common soil, and facing south-west and north-east. In the first spring I had flowering in it the best jewels of the mountain plants—*Androsace Laggeri*, *A. vitaliana*, *Arabis alpina*, *A. aubrietoides*, *A. rosea*, *A. caucæa*, *A. purpurascens*, all the *Aubrietias*, *Drabas*,

Iberis saxatilis, *I. stylosa*, *Saxifraga apiculata*, *S. Albertii*, *S. aretioides*, *S. Boydii*, *S. B. alba*, *S. burseriana* and its varieties, *S. Grisebachii*, *S. Kotschyii*, *S. sancta*, *Daphne blagayana*, *Primula Allionii*, *P. marginata* and *P. hirsuta*. All of these were in flower this year at the end of February, and by the time this note appears I shall have in my wall garden many hundreds of different species in flower—*Alyssum*, *Androsaces* of all kinds, *Armeria cæspitosa*, *Brassica repanda*, *Coluteocarpus reticulatus*, the first flowering *Dianthus*, all the *Erysimums*, *Matthiolas* and all rock-loving *Primulas*.

May and June are the best months of all to see this wall. Every kind of rare plant flowers there with the greatest abundance and ease.

Floraire, Geneva.

H. CORREVON.

CROCUSES NATURALISED IN GRASS.

CONSIDERING the ease with which Crocuses, either yellow, white, lilac or purple, may be naturalised in grass, it is no small wonder that

ORCHID NOTES.

THE LYCASTES.

THIS is a distinct genus not often confused with others, and it embraces about twenty-five species, which for the most part are very beautiful. The majority are natives of Central America, of easy culture, free flowering—in some instances as many as fifteen flowers being produced from one pseudo-bulb—and they remain in full beauty for several weeks, while some possess a pleasing fragrance.

The most popular is unquestionably *Lycaste Skinneri*, which was discovered by Mr. G. Ure Skinner in Guatemala, who brought it to England in 1841, and it flowered for the first time in this country in the following year at Broughton Hall, Manchester, where the Rev. John Clowes had a fine collection. It is still imported from Guatemala and the surrounding districts, and every amateur should procure a few plants of this beautiful winter-flowering Orchid. The blossoms are large and handsome; the sepals and petals are white, flushed with rose; and the lip is almost white, thickly

ALPINE FLOWERS ON MR. H. CORREVON'S WALL GARDEN AT FLORAIRE, GENEVA.

they are now so frequently grown in this effective way. They are seen to best advantage when grown in irregular groups on tree-covered banks or mounds. The grass and *Crocus* foliage ought not to be mown off until mid-May, and after then the grass may be kept mown regularly. Surely there is no sight more beautiful than Crocuses in full flower scattered among the grass on a sunny spring morning. Yellow varieties should be planted alone; the white and lilac varieties mingle well together, as may be seen by the illustration on the opposite page.

spotted with rose and crimson. There are several named varieties, such as *alba*, *picta*, *armeniaca*, &c., which differ from the type in colour. Another fine species is *L. aromatica*, which is golden yellow and fragrant. *L. cruenta* is somewhat similar. Other distinct kinds are *L. gigantea*, *L. candida*, *L. Deppei* and *L. macrophylla*; but for an amateur's collection *L. Skinneri* and *L. aromatica* would suffice.

Cultural Details.—Both of these plants can be grown successfully either in the cool house or intermediate division; but if the former is chosen

it will be advisable to see that the atmosphere is not overcharged with moisture, nor the temperature allowed to drop below 50° Fahr. during the winter months. Lycastes are free-rooting subjects, and should in consequence be provided with ample pot room. The pots ought to be filled one-third of their depth with drainage, over which is placed a thin layer of sphagnum moss to maintain a free outlet for water. The compost is made up of good fibrous loam, Osmunda fibre, partly decayed Oak leaves and sphagnum moss in equal parts. When repotting, press the mixture moderately firm, and the surface should be about half an inch below the rim of the pot. This operation is best done when the new growth is about 2 inches or 3 inches in length. During the growing period they must be supplied with ample water; and although Lycastes require a rest after the pseudo-bulbs are fully matured, they should at no time be permitted to get really dry at the root. Light shading is essential through the spring and summer months, but at other times the plants must be placed in a position where they can receive all the light possible. Red spider will be found occasionally on the under sides of the leaves, which causes them to turn yellow and prematurely decay. To prevent this, the foliage should be carefully sponged at intervals with a weak solution of some reliable insecticide; then the leaves will remain green and the plants present a pleasing appearance, even when not in flower.

T. W. BRISCOE.

ANNUAL FLOWERS FOR AMATEURS' GARDENS.

ONE has only to look around during a summer ramble or a cycling tour to note how rigidly the multitude of amateur gardeners cling to the older styles of bedding-out designs, where are the Zonal Pelargoniums, Lobelias, Calceolarias, Iresines and Ageratums, with, here and there, a sprinkling of Cannas, Fuchsias or Palms as dot plants to relieve the flatness of these somewhat stereotyped forms of bedding. Let it not be imagined that one wishes to see this form of bedding-out eliminated from the flower garden entirely. Far from it, because some very beautiful designs in grouping and colouring are frequently met with; but, on the other hand, in the majority of cases much more might be expected when one calculates the time and expense incurred in the propagation and wintering of the various plants concerned in the formation of these designs. It is a positive relief when one comes across an amateur or gardener who is imbued with a genius for giving a trial to a scheme of bedding-out with annuals in place of those plants just mentioned.

Annuals are peculiarly adapted to the requirements of many amateurs, who, by reason of their occupations, cannot give to their gardens so much time as is required for the propagation and preparation of the first-mentioned plants. Again, if the amateur has to depend entirely upon the nurseryman for his supply of those plants for his beds, his expenses are heavy indeed to what they would be if annuals were used in their stead, and this latter is, to my mind, one of the chief features in their favour, apart from their adaptability to be used in groups and masses, to form many pleasing colour effects, and for cutting purposes.

Sowing.—Most of the hardy annuals may be sown in the open ground from the middle of

firm's packets. Should a very dry period follow immediately after sowing, it may become necessary to assist germination with an occasional sprinkling from the water-can. Birds have a liking for the tender seedlings of many annuals, as they have for vegetables, and protection must be afforded until the seedlings have grown sufficiently strong to do without it. Slugs also must be kept in check with an occasional dusting of soot or lime.

A Selection of Hardy Annuals for sowing during the early months of the year may be helpful: *Acroclium*, *Alyssum*, *Bartonia*, *Calandrinia*, *Calendula*, *Candytufts*, *Chrysanthemums* (coronarium and inodorum varieties), *Clarkias*, *Coreopsis*, *Cornflowers*, *Eschscholtzia*, *Godetia*, *Gypsophila*, *Helianthus*, *Larkspurs*, *Lavatera*, *Lupinus*, *Limnanthes*, *Linaria*, *Matthiola*, *Mignonette*, *Nemophila*, *Nigella*, *Poppy*, *Silene*, *Sunflowers*, *Sweet Sultan*, *Tropaeolum*, *Virginian Stock*, *Whitlavia* and *Xeranthemum*. Many of the above-named are suitable for autumn sowing also.

Half-Hardy Annuals.

Hitherto only the hardy annuals have been dealt with, but one must not lose sight of the very pretty and equally serviceable half-hardy varieties. These latter need rather more care than their hardy neighbours, but the extra care bestowed fully compensates their owner. A warm greenhouse is perhaps the best place in which to sow the seeds, the latter being sown in boxes, pots or pans containing a light, sandy compost, well drained. Care should be exercised not to sow too thickly or too deeply, nor in a soil too wet and pasty, or the seedlings may damp off wholesale soon after they get above the soil. The seedlings should be spaced out into other receptacles by means of a dibber to cause them to grow sturdy; and by the time May comes along they will, by judicious hardening off, be strong specimens ready for planting out. Failing a greenhouse, a frame placed on a hot-bed makes a very serviceable structure in which to sow and rear seedling half-hardy annuals during the early stages of their growth. They may be gradually inured to cold-frame conditions as they gain size and strength. A selection of half-hardy annuals may be made from the following: *Asters*, *Arctotis*, *Balsams*, *Cockscombs*, *Gaillardias*, *Lobelias*, *Marigolds*, *Nemesias*, *Phlox Drummondii*, *Portulaca*, *Ricinus*, *Salpiglossis*, *Stocks*, *Tobacco Plants* and *Zinnias*.

A last word may be appended *re* *Mignonette*. To grow good specimens the ground should be made very firm in which the seeds are sown. In some districts *Mignonette* is very unreliable when sown in the open. To avert disappointment it is wise to sow three or five seeds in a 2½-inch pot of light compost and plant the seedlings outside when established.

J. C. WADD.
92, Moore's Road, Belgrave, Leicester

NARCISSUS W. P. MILNER, A PALE SULPHUR VARIETY OF MODEST SIZE, SUITABLE FOR ROCKWORK. (See page 151.)

March until the middle of May, and many of them are suitable for sowing again during August and September to provide an early display of bloom the following year. If it is decided to sow them where they are to flower, the soil must have been well dug and weathered beforehand, so that when raked down a fine tilth will be the result. The smaller kinds of seeds should be sown broadcast thinly over the prepared surface (having first inserted the label of the variety being sown), and then covered with a little finely sifted soil from a box or barrow. Larger seeds may be dibbled into position at a depth and distance suitable to their requirements, stated plainly on most

GARDENING FOR BEGINNERS.

SPRING WORK IN THE GREENHOUSE.

AT no season is work more pressing in the greenhouse than the early part of spring. Thousands of plants must be raised now, either from seeds or cuttings, and on this work depends, chiefly, the success of plant cultivation during the greater part of the year. Even those who have had considerable experience are obliged to very carefully consider this matter, and those who are inexperienced welcome hints that will be helpful to them. All

Old, Leggy Plants are not useless if they are properly treated. There are many specimens of this description in greenhouses. It is necessary to cut off the tops of some and discard them, relying upon the old stems to produce young shoots. There are others that may be topped and the tops rooted, as well as side shoots that are produced from the decapitated stems. The possessor of a warm propagating-frame may quickly strike the removed tops. Others, who cannot command a warm propagating-frame, may treat the long-stemmed plants as shown in Fig. 1. Greenhouse *Dracenas*, *Ficus elastica* and similar kinds of plants may be treated in this way. About six inches beneath the lowest leaves the stem should be cut, as shown at No. 1, denoted by the arrow. Keep open the lip by inserting a stone or a piece of charcoal. Then procure a pot, No. 2, deep and narrow, and split it to form two halves, fix it to the stem, bind it with wire, and support it firmly in position to two stakes driven into the soil in the large flower-pot. Then

REDUCING A LONG-STEMMED DRACENA BY "RINGING" THE STEM.

fill the stem pot with leaf-soil, sand and loam in equal quantities, and keep it in a uniform state of moisture. Before midsummer stem roots will have taken possession of the soil in the pot, and then the main stem, just below the pot, must be gradually severed. Keep the severed top in a shady place and continue to water with the same care. Now, a number of young side shoots will grow from the old, bare stem if it is syringed daily. These new shoots will be available for removal next spring and form nice cuttings for propagation. The old stem, after their removal, must be cut down to 6 inches above the soil in the pot. From this old stump a strong young shoot will grow, and in due course form a nice plant on the original one and in the original pot. Repotting may then take place, the old stem, No. 3, being replaced by a vigorous, low-grown head. *Cannas* are

Noble Greenhouse Plants. Seeds sown in pots filled with a sandy mixture and plunged in a mild hot-bed soon germinate. They take a much longer time if not subjected to bottom-heat. They are very beautiful, the foliage, as well as the *Gladiolus*-like flowers, having a noble appearance in a greenhouse. The temperature of the latter is just suitable to a steady, luxuriant growth. No. 1, Fig. 2, shows a strong seedling plant ready for potting separately. No. 2 depicts the proper depth to plant.

Old Roots or Tubers may now be started into growth by placing them in boxes and just covering the tuber portion with leaf-soil, loam and sand. When well rooted and the new growth is proportionately advanced, pot each old root separately, as shown at No. 3. A position on a side stage fully exposed to the sun's rays will do nicely, as full light is conducive to that rich colouring of the leaves. Feeding is neither necessary nor desirable until the plants have filled their flowering pots with roots; then stimulants, wisely given, will strengthen the flower-stems and individual blossoms.

Standard Heliotropes and Fuchsias.—These should be more generally grown in greenhouses than at the present time, because they give a unique appearance to such structures. Their presence, either on the floor or on the stage, takes away the formal appearance of the dwarf pot plants. Standards of substance are not grown in one season—they require treatment over at least two years—but a beginning must be made, and so why not start now? Select a few long-stemmed young plants propagated last year, repot them forthwith and stake them. Do not pot very firmly and use a rich compost. In a few months' time these plants will be 20 inches high or so, and possess thick stems. Then repot again, but press the soil more firmly, and so induce additional growth with riper wood. When of the desired height, top the plants, and allow side shoots to grow and form the basis of the head.

Begonias, Gloxinias, Gesneras and similar kinds of plants now making leaves freely need not be grown under such heavy shadings as one sometimes notices. One of the best collections of tuberous *Begonias* the writer ever saw was grown in a cool greenhouse without any shading

STURDY CANNA SEEDLINGS READY TO POT ON AND AN OLD ROOT STARTING INTO GROWTH.

The aspect was south-west. Careful ventilation and watering are the principal points to note. G.G.

THE EFFECT OF MIXED MANURING.

IN mixing manures there are other things to consider than the possible detriment which the process may involve to the several ingredients. The latter is, of course, a matter of much practical importance in some cases, but we should also consider the effect on the plant. The subject is still an obscure one, and experiments are conflicting, but they sometimes show startling results in favour of combined over single manures. Often enough, two manures favourable when used separately will do better in combination, and sometimes the sum of the separate results is exceeded. It is very difficult, of course, to say which is the predominating partner, but some guide is afforded by the relative effect of the added manure. The nitrogen added, for example, may give much more effect than phosphate added each one to the other or to potash, and some very discordant results have been obtained merely by this means. It is not, then, merely a question of using different manures containing the same plant food in different forms, for this we know will give an infinity of varying results; but the relative order of using and changes in the quantity used, and especially season and soil, will often be factors to reckon with. Dealing generally with mixtures, it has been assumed that if nitrogen alone does well for a crop, it will give the same relative results in a mixture, and that possibly other manures will do the same. This is mere conjecture, however, though nitrogen generally gives a better return than other manures when applied alone; but when used with superphosphate, for example, it seems very probable that its relative action is not the same. There are reasons for this, because manures in mixture may not act directly on the plant; they may react on each other, to their mutual or individual benefit, or on the constituents of the soil, or in more complicated ways. GERVASE TURNBULL.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Early Pot Vines.—These will have finished stoning, and will require careful watering and feeding. Examine the pots several times daily and give liberal supplies of manure in a liquid form. A light top-dressing of loam and artificial manure may be applied, and should be made firm on the surface of the soil. Keep up a brisk heat until the Grapes have finished swelling, after which a little more ventilation may be necessary to colour the berries.

Melons.—The early plants, having set their fruit, should now be given a brisk heat, with plenty of atmospheric moisture. The fruits should be supported by some means before they are large enough to injure their stems through their own weight. Give liberal supplies of water at the roots, and stop the lateral growths before the trellis becomes overcrowded. A light dusting of Le Fruitier will be found beneficial to these during the swelling period. Ventilate with great caution, always avoiding cold draughts. The night temperature may be from 70° to 75° in mild weather, rising 10° by day with sun-heat.

Strawberries in Pots.—By this time the early batch of Strawberries will be in an advanced state. During the ripening stage air should be given more freely, and the atmosphere may be kept less moist. Expose the fruits to the sun by means of small forked sticks. Continue to introduce plants into heat as space becomes available.

Plants Under Glass.

Pot Roses.—The latest batch of plants should now be introduced to mild heat. Plants which are showing flower will benefit by frequent waterings of liquid manure from the farmyard, and later plants may receive a surface dressing of loam and artificial manure. Avoid cold draughts, which are almost sure to produce mildew. Plants of

Hydrangea hortensis which have been wintered in cool quarters may now be started into growth in numbers, according to the requirements of the place. Others may be retarded in a cool north house, and will be valuable for decoration during the summer. The early plants may be watered freely with liquid manure and grown in a temperature of 60° until the flowers are fully developed.

Ixoras.—The present is a good time to prune, clean and repot any plants which require it and are intended for flowering later in the season; but the earliest flowers are obtained from plants which were potted late in the season, and only require cleaning and top-dressing now.

Perpetual - Flowering Carnations.—Young plants raised from cuttings early in the year should now be ready for potting into 4-inch pots. It is a mistake to grow young Carnation plants in too much heat, as this will produce weak, spindly growth, which is never capable of producing satisfactory flowers.

The Flower Garden.

Hyacinths and Early Flowering Tulips are now throwing up their flower-spikes, and should receive support at once, as a rough wind may soon spoil the effect by breaking off some of the finest blooms. After the supports have been placed in position, the surface of the soil should be carefully broken up with a small Dutch hoe.

The Rose Garden.—Continue the pruning of dwarf Roses. All spindly shoots should be cut to within a few eyes of the base. At the same time, all wood which may have been injured by frost should be removed. The tying of all climbing Roses should now be finished. In positions where the plants are exposed to the sun, a mulching of cow-manure should be applied before the season is too far advanced.

The Kitchen Garden.

Cauliflower.—Plants which have been wintered in cold frames should be gradually hardened off in readiness for planting out in the early part of April. Remove the lights by day if the weather is favourable, and allow a fair amount of air during the night. Careful attention should be given

to watering, as, once the plants become stunted, the result will not be satisfactory. If the pots are well filled with roots, weak liquid manure may be applied with advantage.

Leeks.—The main batch of Leek seed should be sown as soon as the soil is in good order. Sow in shallow drills a foot apart.

Brussels Sprouts.—There should be no delay in sowing the main crop of Brussels Sprouts. A sheltered border should be chosen for the purpose, for although seeds were sown under glass a month ago, the best results may be expected from plants which have been grown in the open from the beginning. Ideal, Dwarf Gem and Sutton's Exhibition are good varieties.

Cabbage.—Seed should be sown now in the open border for cutting in July and August. This is a much better practice than to depend on a second cutting from plants which were put out in the autumn.

Cauliflower Seed should be sown every three weeks from now until the middle of May, and the plants of each batch grown without a check, so that an unbroken daily supply may be kept up throughout the summer and autumn. Great Dane, Magnum Bonum, Early London and Hallowe'en Giant are extensively grown at Frogmore, the last-named variety for the latest supply.

Lettuce.—Plants raised from spring-sown seed should now be ready for planting in cold pits or on a warm south border. Make a sowing of Lettuce seed every ten days, choosing, as the season advances, cooler situations and suitable varieties. For early supplies out of doors Pioneer and Golden Ball are good Cabbage Lettuces, while Mammoth White Cos is one of the best for early summer supplies.

The Hardy Fruit Garden.

The Protection of Fruit Blossom.—Careful attention should be given to the protection of Peach, Nectarine and Apricot blossom whenever there is the slightest danger of frost.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Potatoes.—In most cases the main crop of Potatoes may now be planted, or at any rate before the end of the month. It may not be out of place here to emphasise the importance of giving sufficient room, not only between the rows, but also between the sets. For strong-growing varieties the distance between the rows should not be less than 30 inches, and that between the sets 15 inches. Assuming that the Potatoes were placed in boxes some time ago, they should now be nicely sprouted. If time permitted, it would pay to go over them and reduce the sprouts on each set to two at most. Small and medium-sized Potatoes should be planted whole, while larger tubers should be divided. By all means avoid planting too close, which often proves very harmful.

Salsify.—In the majority of gardens one sowing of Salsify will suffice, which may be made now. The soil for this crop ought to be fairly deep, and manured the previous season, such as the Celery ground. The object should be to get long, clean roots. I find there is now a greater demand for this vegetable than there has been for some years, and that is not to be wondered at, seeing that it supplies a fine dish when vegetables are scarce.

Celery.—Seed of the main crop of Celery may now be sown, and for all practical purposes this sowing will in most cases meet all the demands of the average household. When the seedlings are large enough, they may be pricked into frames, and if some well-rotted manure has previously been forked in, they will grow very rapidly, and will lift with good balls of soil for planting. When time permits, the trenches may be got ready. One generally finds that the soil will work better now than later.

Broccoli and Winter Greens.—Seed of the autumn varieties of Broccoli may now be sown, as well as that of Savoy and other winter greens.

The Flower Garden.

Summer-Flowering Chrysanthemums.—Old plants may now be divided and replanted, and if cuttings are preferred, it is not too late to put in a batch. These will root in a short time, and will be ready to be put out with the other bedding plants.

Herbaceous Pæonies.—These lovely early summer-flowering Pæonies, so useful for cutting, resent being disturbed at the roots. That being so, it will be necessary to top-dress or fork in some good turf and a little old manure. This will greatly increase the size and quality of the blooms.

Bedding Begonias.—The tubers may now be looked over and planted in frames, and watered slightly from time to time to enable them to start into growth. They must be exposed to all the light and air possible, so that they may be encouraged to make sturdy growth, which will be less likely to be damaged when planted out.

Antirrhinums.—Where the seed was sown at the end of January or the beginning of February, the young plants will be ready for pricking out, and for this purpose I prefer boxes, which can be kept closer to the glass than if planted out in frames. Aim at having nice sturdy little plants for planting out.

Lawns.—The present will be a suitable time to top-dress mossy or bare patches on the lawn with a compost of sifted soil and sand in which some lawn grass seed has been added. These patches will require to be protected against sparrows, otherwise they will make short work of the seed. All trimming of grass edges may now be proceeded with, and sweeping and rolling of the lawns may now be done.

Plants Under Glass.

Eucharis amazonica.—These once indispensable flowering stove plants are not now so largely grown as they used to be, due, no doubt, to the fact that stove plants generally are not in such demand. They are to a certain extent very accommodating, as they can be had in bloom at various seasons of the year, according to the treatment. Unfortunately, the mite that attacks the bulb is very difficult to get rid of, and is responsible for the destruction of many fine collections. When this is present, one has to take drastic measures to eradicate it. There is nothing for it but to shake the bulbs out of the pots and wash them thoroughly with an approved insecticide. Plants that have been partially rested may now be introduced into a little more heat. Those that require potting should afterwards be plunged in a hot-bed and watered very sparingly at first; indeed, frequent syringing will be all that is required for a time.

Bouvardias.—Plants that were placed in heat some time ago will now be commencing growth, and a start may be made in getting the cuttings put in. They had better be placed in the propagating-case and slightly shaded, as sometimes they are troublesome to root. When the young plants are well rooted, the leading shoot must be pinched to ensure a sturdy habit.

Calanthes.—These will now be showing their growth, and may be taken out of the pots and thoroughly washed to dislodge any scale that may be on the bulb. They should be potted in a mixture of good turfy loam, dried cow-manure and charcoal, and placed on a stage in a warm house and syringed several times a day.

The Hardy Fruit Garden.

Cherries.—The early varieties will now be in flower, and should be protected with a double herring-net. This will be found to be a grand protection against heavy storms of sleet and rain, which do such havoc just as the flowers are setting.

Vines.—Now that the sun has increased power and with the prevailing cold, cutting winds of this season, great care will be necessary to prevent the tender foliage becoming scorched. The slightest carelessness in airing will do great damage to the foliage, and, consequently, will check the swelling of the berries. The man in charge should see that there is a nice warmth in the pipes in the early morning before admitting air, and this must be done very cautiously.

DAFFODIL NOTES.

Correction.—I am very sorry to find that I persistently used the name *Distinction* for one of the new "Vis" Poetaz that I wrote about in my last notes. I should have said *Admiration*. I hope this bit of stupidity on my part will not cause anyone any inconvenience, and that they will end by getting hold of the right thing should they wish to try it, which I again take the opportunity of urging upon those who like something new and good. There were a few excellent examples of this striking novelty on Messrs. Barr and Sons' stand at the Royal Horticultural Society's Bulb Show on the 10th inst.

The New Poetaz.—The plants that I mentioned in *THE GARDEN* of March 7 have now bloomed. Three are down in my private notes as *Ar*. I think, too, that I may generalise now about another feature of this new type. On the whole, the cups are not only larger, but they are also undoubtedly, in many cases, flatter. Irrespective of all else, why is it that these "flat cups" or eyes are so strangely effective? They always seem to be the just-what-is-wanted to set off a flower. My special favourite, *Orange Blossom*, has this telling gift of the gods, and I account it one of its greatest charms. Among those sent me for trial by Messrs. M. van Waveren and Sons, I find this characteristic fully developed in *Haemon*, which is an all-yellow. As usual, the centre is of a deeper shade than the perianth, which in this case is somewhat undulating. As I have already hinted, the centre is flat and large, as these actual dimensions prove: Diameter of the flower, $2\frac{1}{4}$ inches; of the eye, seven-eighths of an inch. The stem is tall and strong, and each one bears on an average five well-placed blooms. My *Ar* trio is completed by *Lucrece*, which is similar to my favourite *Orange Blossom*, and *Antigone*, a white and yellow, with the eye large and flat. The plant itself is on the dwarf side.

Following the above come in order of merit *Mignon*, a pretty flower with a small, bright orange red cup and white perianth; *Sovereign*, an improved *Irene*; *Yoconde*, a sort of smooth, round-stemmed *Sunset*; *Bouquet Enovme*, with a look of the old *Ideal*; and *Eurydice*, a large cupped and dwarf *Triumph*. Mr. H. Prins of Lisse exhibited under numbers a collection of about a dozen at the bulb show, but there was none that excelled the trio above mentioned. It is, however, only fair to say that with better staging or arrangement they might have appeared to greater advantage.

The Show Generally.—I believe the official mind of the Royal Horticultural Society will not allow that the exhibition on March 10 and 11 is, or was, a forced bulb show; but as such the public regard it and speak of it. I only hope the Council will see the wisdom of coming into line and encouraging more than they do now exhibits more in consonance with its popular appellation. We want early Tulips in pots and Daffodils in pots to fill up what certainly is a bit of a gap. The inclusion of these would do so much to remedy the defect. Two groups of Daffodils received silver-gilt Banksian medals, viz., those of Messrs. Barr and Sons and Messrs. Cartwright and Goodwin. Both displays were excellent. I was glad to note the collection in bowls (grown in fibre) of Messrs. James Carter and Co. This received a silver *Flora* medal, but when the merits of the cinerary garden were added, the Council said, "Friends, go up higher,"

and the *Narcissus* committee's medal became a silver-gilt *Flora*. That old urn (in shape like a pierrot's hat made in clay, the top cut off and then turned upside down) on its pedestal in the midst of a lovely smooth, green lawn, edged on one side with pretty pink Tulips and other nice flowers, and on the opposite one by an open panelled wall surmounted with bright bits of colour and the dark green of evergreen trees, was, so it seemed to my fancy, both allegorical and prophetic, as well as being the centre of a well-conceived harmony.

The New Awards.—The new system of granting awards to Daffodils according to their suitability for certain purposes came into operation for the first time. An award of merit for its suitability for growing in pots was given to *Olympia*. Two excellent examples were placed before the committee, with the result that the high opinion I have always had of this fine variety has now had the imprimatur of the committee. As a plant for pots *Olympia* comes easily, is very free, and has blooms of a remarkable size. It will be of interest, perhaps, to some to know that this variety does well in California, where a brother of Mr. F. Herbert Chapman is living. This gentleman is very keen on Daffodils. At a show at San Francisco on March 27 to March 29, 1913, he exhibited an *Olympia* of his own growing which measured " $5\frac{1}{2}$ inches across."

The other plant that received an award was *W. P. Milner*. This was for its suitability for rockwork. Everyone was in accord in singing its praises for this purpose—dwarf, free-flowering, of good constitution, and of a dainty, striking shade of sulphur yellow, only about a shilling or fifteen-pence a dozen. No one can possibly go wrong in giving it a trial in one or two pockets in their rockery. I wonder why it was not entered for a "pot" award. For 4-inch and 5-inch pots it is quite without a rival and comes almost a pure white. While dealing with these new awards, may I say that when they are given to varieties that have been in commerce for a considerable number of years, the public may be sure that such have been well tested, and that all their merits and demerits must be intimately known; hence the greatest confidence may be placed in them, only buyers must be careful to find out the reason for which they are given, if it is not absolutely clear in the catalogue where they are listed. They should appear like this:

Olympia—Award of merit (pots), March 10, 1914.

W. P. Milner—Award of merit (rockwork), March 10, 1914.

Notable Varieties.—A detailed list must be left until next week. All I can do is to record the first official presentation of *Queen of the West* to the buying public by its owner, Mr. Walter Ware. The raiser (Mr. H. Polman Mooy of Haarlem) came all the way from Holland to see it make its debut.

JOSEPH JACOB.

IS THE DAFFODIL A FLORIST'S FLOWER?

"A WORKING-MAN Florist for Fifty Years" (I wish gentlemen who write over a *nom de plume* would use shorter ones) in your issue of the 14th ult. says the criterion of a good Daffodil in 1820 was: "Strong, erect stems, regularity of form and disposition of the petals and nectors, distinctness and clearness of colours." And he asks if the above ideal is not good enough for anyone? It is certainly good enough for me, and for, I

think, most, if not all, of those who may be said to constitute the present Daffodil world. "A Working-man Florist" then goes on to ask, with great satisfaction, apparently, as if being sure that the answer will unanimously be in his favour, "How many of the recently boomed new varieties are anything near the standard laid down by men who had no axes to grind?" I unhesitatingly say that all the varieties that have received the almost unanimous approval of the Daffodil world during the last, let us say, five years are not only near, but comply with, every one of the points contained in the 1820 ideal. Unless a variety has these points, the raiser or introducer has not a very valuable property, and I cannot call to mind any new varieties that have been boomed by the present Daffodil world that have not all the 1820 ideal points in a pronounced degree. Without referring to catalogues or books, I will mention a few varieties that I suppose would come within the description of "recently boomed varieties," and ask any unbiased lover of flowers whether they do not all possess the points required in 1820. The varieties that occur to me and varieties which I know to be good growers are *Miss Willmott*, *Challenger*, *Empire*, *White Star*, *Bernardino*, *Heroine* and Mrs. E. H. Krelage. If "A Working-man Florist" would take any good Daffodil catalogue and ascertain the correct characteristic of the flowers he designates as "the boomed new varieties," I think he will find that they all comply with the 1820 ideal. I can fancy that many of the present raisers of Daffodils will say, "Why write all this?" Well, my reason is that I think the general statements, which are clearly incorrect, should not be allowed to pass without comment, as nothing is so easy as to make general statements, and nothing more difficult to controvert than such statements if they are allowed to sink in and become members of that very large family sometimes called "vulgar errors." If there is one thing which is more pleasing than another in the Daffodil hobby, it is the strong and healthy views which its followers have as to the qualities that are required for a flower to receive anything more than a passing notice, and there is a tendency every year for a more and more strict observance that a new variety, to be of any real value, should combine the following points: "Strong, erect stem, regularity of form and disposition of the petals and nectors, distinctness and clearness of colours."

C. LEMESLE ADAMS.

CANKER IN FRUIT TREES.

I WAS greatly interested in "Scientist's" reply to a correspondent on page 56 of *THE GARDEN* for January 31, but cannot agree with the impression that he wishes to convey to your correspondent—that this disease can only be brought about by the fungus entering through bruised or cracked bark. So far I can agree with him that the fungus can be carried by wind, and if such wounds are there to receive it, it will spread. But how can "Scientist" account for this attack? During the autumn of 1909 I formed a new kitchen garden here. The soil in one part is a rather heavy clay, the other a light sandy loam. This ground had not been broken up during the memory of the oldest inhabitant; therefore the top spit was composed of a rich deep fibre, ideal for fruit cultivation. In early spring I planted a few dozen Apple trees

On the light loam I put a row of five trees, and among the varieties were Lord Suffield, Lord Grosvenor and Wellington. In the following autumn they showed signs of canker, and the year following I took them out and destroyed them, as every branch was affected. The ground was retrenched, limed, and five trees of Apple James Grieve planted in their place. They showed the same tendency by the autumn as the others had done, and this year they were so bad that I had to destroy them rather than risk infecting the others. Now, both these lots of trees came from first-class fruit-growers, and none had any bruised or broken bark on them to my knowledge, and were clean, healthy plants in every way. As for late frosts splitting the bark, we are not subjected to them in any degree in this part. Further, the old garden is not within 300 yards of the new; therefore I cannot see how the spores could have been carried from it on to these certain trees. Moreover, among the few hundred trees now in the garden are varieties quite as subject to canker as those mentioned, and I have only found one other affected tree of the variety Norfolk Beauty growing on the same kind of soil. In the old garden, which is now given up to the cultivation of shrubs and flowers and a few old fruit trees, even that sterling variety Bramley's Seedling is badly affected with it, and to plant young trees was useless, as after two years they were so bad that they had to be destroyed. A gardener friend not far from here told me that the same thing happened with all young trees he planted. I am convinced that soil, situation and choosing the right varieties for the district that one lives in play a more important part in combating this noxious disease than we imagine.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

TREATMENT OF ORNITHOGALUM LACTEUM (J. W. M., South Devon).—While *Ornithogalum lacteum* can only be regarded as a greenhouse plant in most parts of the country, it is quite likely that in your favoured climate it will succeed out of doors. Your suggestion to plant the bulbs at the foot of a very warm wall, using plenty of sand at the base, is a good one and should ensure success. In planting the bulbs they should be placed at such a depth that there is 6 inches of soil above the topmost portion of the bulb. Should sharp frosts occur after the bulbs are planted, a little protection should be afforded them.

WATER LILIES AND GOLD-FISH (Garden).—You cannot do better than place gold-fish in your pond if you wish to have fish at all. They are not likely to stir up mud any worse than other kinds of fish. The following Water Lilies would make a good selection: *Nymphaea alba* and its variety *candidissima*, white; *N. fulva*, red; *N. William Falconer*, red; *N. William Douce*, red; *N. tuberosa flavescens*, yellow; *N. odorata sulphurea*, yellow; *N. Marliacea carnea*, flesh-coloured; *N. M.*

flammea, red; *N. gladstoneana*, white; and *N. robinsoniana*, red. If you plant a clump or two of the Narrow-leaved Reed Mace, *Typha angustifolia*, about the margin, it will relieve the flatness and furnish the cover you desire better than Watercress. A few clumps of *Caltha palustris* and common Ferns planted about the brink will be an advantage.

PLANTS FOR PONDS (Co. K.).—You cannot do better than plant *Nymphaea William Falconer* (red) in one pond and *N. gladstoneana* (white) in the other one. Two good upright-growing plants for the margins are *Butomus umbellatus* and *Typha angustifolia*, with *Acorus Calamus variegatus* if you wish for a little colour. Dwarf plants for the water are *Menyanthes trifoliata* and *Aponogeton distachyon*. It is better to make mounds of soil on which to plant the water plants, rather than spread a layer of soil over the bottom of each tank. Such mounds may be built with good strong turves and be kept in position with the aid of bricks. Or, if you so wish, each plant may be placed in a basket of soil in the pond. To darken the margins of your cemented ponds, mix a little soot with cement until the right shade is obtained, and wash the cement work over as with any other colour wash. Try root-pruning your plant of *Chimonanthus* in July. That may make it flower. Simply chop round the plant with a spade about two feet from the stem. Also leave the branches unpruned this year. If you water your pot plants with soot-water, many of the worms will come to the surface and may then be removed. Mustard-water is even more efficacious. It ought not, however, to be used for delicate plants.

MAKING A MORaine (T. H. G.).—The chief essentials of the moraine are moisture in conjunction with the poorest of soils—sand, grit, rock—as opposed to the richer vegetable soils. You ask for the proportions of different rock to suit certain plants and situations. It is well known, however, that whatever the likes or dislikes of certain alpine plants appear to be when under cultivation in the ordinary way, they disappear as if by magic when planted in the moraine, those from granite rock and others from limestone doing equally well side by side. The moraine should be situated in full sunshine, and the necessary moisture being forthcoming, should render it a success. In the first place, a water-tight bottom should be arranged; following this, beds or compartments at varying depths, the overflow from the upper supplying the lower, and all having an inclination to a prearranged outlet. Above the concrete floor place a 6-inch-thick layer of rather coarse gravel, then a layer of moss or like material to prevent the finer sand particles being silted through, and above this a few inches of grit, pulverised rock and granite chips, with finely sifted peat and leaf-soil in proportion to one-sixth for the majority, adding a little loam for *Gentian*, *Primula* or *Ranunculus*. With your bank-like arrangements of rockery, the moraine should be placed at its base, the water supply being from below and under control. In your case a series of small moraines may take the place of one with divided compartments. The genera most suited include *Androsace*, *Campanula*, *Dianthus*, *Primula*, *Silene*, *Wahlenbergia*, *Soldanella*, *Eritrichium*, *Ramondia* and *Ranunculus*, though many plants will be found to do quite well that hitherto have not succeeded in the ordinary rock garden. You should obtain "The Small Rock Garden," by E. H. Jenkins, published at these offices for 2s. 10d., post free. It contains a valuable chapter on the moraine, with a good list of suitable plants.

DELPHINIUMS (E. H. S. E., Troy).—These plants are generally considered good for flowering to the third year, assuming that a start was made with youthful examples of two or three crowns each. At the end of that period they would be best divided in spring; here, in the Old Country, it is done in March or early April when the new growth is a few inches long. To successfully divide the plants they should first be washed free of all soil, and then, laying the plant on its side on the potting-bench, insert the point of a strong knife into the woody portion of the rootstock, and half cut, half wrench the plants asunder. In replanting, bury the crowns about two inches deep. It is a mistake to plant big clumps of these and many other herbaceous plants intact; the youthful examples are capable of much better work. If you could so arrange matters as to divide and replant a portion of your stock each year, you would obtain a succession of bloom, the young plants usually flowering in August. A similar result would ensue by cutting down a portion of the plants the second or third week in May; or, in the case of big clumps, thinning would be a good substitute. Were you to arrange the plants informally in groups of three, the thinning out to near the ground-level of some of the stronger stems would scarcely be missed, and a secondary or successional flowering would appear practically on the same ground minus the gaps inseparable from cutting down whole plants here and there. You would, of course, have to be prepared for an inferior second flowering, whether from youthful examples or cut-down plants, since, by removing the earlier-formed shoots, only secondary buds remain, not all of which, though they may become active, would be strong enough to flower. In this second flowering, too, there is a greatly diminished stature, the plants losing much of their fine presence. We have thought it well to give you the *pros* and *cons* in the case, so that before acting you will know what to expect.

SOWING SWEET PEAS (Nemo).—The best results are obtained by sowing in the autumn, say, from the middle of September to the middle of October, wintering them in a cold frame or house, and potting on into their flowering pots about the first week in February. (1) If very dwarf, stocky plants are desired, the Cupids are certainly the best, but they are hardly what we should recommend, as the blooms are naturally small and short in the stem and not so useful as the ordinary varieties—

either Spencers or *grandifloras*. If your house is not very high, you might try King Edward VII., Dorothy Eckford, A. J. Cook, Cerise Spencer, Carmine Spencer and Scarlet Monarch; these are a few of the dwarfest of present-day varieties. (2) The soil employed should not be extra rich, and should consist of three parts good turfy loam, one part well-rotted manure and one part coarse sand or grit, to which may be added a 4½-inch potful of bone-meal and the same of soot to each barrow-load. Using pots from 9 inches to 12 inches in diameter, three to four plants in each pot should make really good clumps for staking with four Bamboos tied at the top to a wire circle from 1 foot to 15 inches in diameter; this keeps the stakes steady, and, if the plants are allowed to grow naturally, all that is necessary is to run a string of raffia right round the stakes as the plants make growth. (3) After the plants are potted, which, by the way, should be done very firmly, very little water will be required for a time, though, as the plants make growth, they must not be allowed to suffer. The temperature of the house must be kept fairly low at all times, giving plenty of ventilation during bright, sunny weather, and only sufficient fire-heat at night to put the temperature at from 40° to 45°. Too high a temperature or too much or too little water at the root when the flower-buds are forming is apt to make the buds drop, so that at this period extra attention is necessary; but as soon as the blooms commence to open nicely they will begin to take water and manure *ad lib.* Cow-manure and soot every alternate day, with a dressing of a good compound fertiliser once a week, should keep them growing well, and the syringe may be freely used to keep down fly and to keep the atmosphere of the house just moist during bright weather.

TREES AND SHRUBS.

PRUNING SHRUBS (O. N.).—Plants of *Euonymus* and *Cotoneaster* may be pruned at once if they require it. Gorse, Broom and *Choisya ternata* must be left until after the flowers have fallen. You cannot do much good by laying a Gorse hedge as you would a Thorn hedge, and it would be much better to cut it down to the desired height. Plants of Broom must not be cut below the base of the previous year's growth. Neither *Cotoneaster* nor *Choisya ternata* requires regular pruning.

CLIMBERS OVER TREES (V. C.).—*Clematis montana* and its varieties may be procured from any of the leading nursery firms. They ought to thrive on the trees you mention, providing you take care that they have a bed of good soil, free from tree roots, in which to grow. *Wistaria chinensis* and *W. multi-juga* are both likely to grow successfully in the positions you describe, and good Roses for your purpose are *Rosa moschata*, Dorothy Perkins, Hiawatha, Alberic Barbier, Edmond Proust and Gardenia. Other climbers suitable for the purpose are *Akebia quinata*, *Celastrus articulatus* and *Aristolochia Sipho*.

THE GREENHOUSE.

INSECTS ON ROOTS OF FERNS (A. J.).—It is possible that you might destroy the insects of which you complain if you watered the plants now and then with soot-water. We do not remember having observed such insects in soil before, and are at a loss to account for their presence. If the soot-water does not kill them, wash the soil away from the roots of any plants that cannot be hurt by so doing, and repot the plants in fresh soil.

AFTER-TREATMENT OF FORCED BULBS (H. H. G.).—Bulbs that have been forced can be turned out of their pots and planted thickly in the open ground, provided they are protected from frosts. As the foliage produced under glass is very tender, it will, of course, suffer unless protection be given. In time the leaves will die away and the bulbs go completely to rest. Then, in July, they may be lifted, cleaned and stored in any dry shed or similar spot. In September they may be planted out, using them for filling spaces in borders or like positions, as, of course, their flowers will be comparatively poor, but they will provide a bright patch of colour in the season. The bulbs may, after they have been lifted, dried and cleaned, be stored in bags or boxes until they are required for planting. They must not be kept in too hot a place.

TREATMENT OF ASPIDISTRA (Gorton).—The reason of the unsatisfactory condition of your *Aspidistra* is that it is practically starved and needs repotting. This operation is best carried out in the month of April. A suitable soil may be made up of loam, leaf-mould and sand. In a general way it will be more satisfactory to apply to a local florist, stating the purpose for which the soil is required. It will cost only a few pence. Judging by your sketch, the rhizomes or creeping stems from which the leaves are produced are quite above the soil, and the plant is thereby starved. Apparently, your plant would be better divided into two, which would appear to be an easy matter. The rhizomes, or underground stems, naturally creep towards the edge of the pot, this feature being more apparent in some individuals than in others. In selecting the pots for the divided plants, care should be taken that they are not too large, and are at the same time quite clean and effectually drained by means of some broken crocks. When potting, the crown or growing point must be placed in the centre of the pot, and the rhizome at such a depth that it is covered with about half an inch of soil. This should be pressed down moderately firm and made even. When all is neatly finished, the plants should be watered through a fine rose in order to settle everything in its place. After this, watering must be carefully done, as, if the soil is kept too wet, the roots would be injured. Although the *Aspidistra* needs plenty of light, it should not be exposed to direct sunshine.

THE GARDEN.

No. 2210.—Vol. LXXVIII.

MARCH 28, 1914.

NOTES OF THE WEEK.

Trees Damaged by Gale.—Considerable damage has been done to trees in various parts of the country by the strong gale which last week swept over the British Isles. At Kew a large Lombardy poplar, one of a pair standing either side of one of the principal walks, had its upper part blown down. More serious, however, was the damage done to a remarkably fine specimen of the Tulip Tree standing near to the Rhododendron walk, which was completely wrecked. This specimen tree was well known to visitors and students and will long be remembered.

A Gentian Blue Flower.—*Chionodoxa sardensis* is one of the few flowers which may without the least exaggeration be termed "a gentian blue." It is brighter and more pleasing than the well-known *Scilla sibirica*, and it comes into bloom a week or two earlier. From observations made during the windy and rainy weather which we had in the first half of March this year, it seems better able to stand rough usage than its stable companion, *Lucilia*, which is illustrated here. Both of these varieties, as well as the larger and more mauve-coloured *gigantea*, are very much stronger in growth when they are left undisturbed for several years. Newly planted bulbs bought in the usual way from dealers are never at their best the first time they flower.

Sowing Seeds in Wet Soil.—The excessive cold rain that has been experienced in most parts of the country during the present month has made the soil very cold. It is, therefore, necessary to point out the folly of sowing seeds until the water has drained away and the soil become warmer. If put into cold, wet soil at this season, a great many seeds will decay instead of germinating, and the seedlings, in nine cases out of ten, be wrongly named. Even when the weather has improved it is a good plan in heavy soils to prepare some old potting soil or other light material to put in drills before sowing such fleshy seeds as Peas,

up for early cutting in, say, the first and second week of March. Not a single catalogue that we have seen mentions their adaptability for this purpose. When these Grape Hyacinths are grown under glass, we get quite a long stem—10½ inches is by no means an unusual length—and as they are very strong and wiry, the mixture of blue and white, or the blue alone, make charm-

or conservatory may be glad to know how useful both *Etna* and *Cavaignac* are in this respect. Grown under the same conditions as other varieties, they come into flower quite at the tail end of the family, when most are past their best. *Etna* is a broad-petalled, bright rose, edged deep blush. It forms a compact, not overcrowded spike, and, from what we can learn, it is a most

reliable "doer." *Cavaignac*, which is an older variety, has much the same habit of growth, and is equally good for growing in pots. It may be described as a bright salmon rose, a shade of colour which is none too common in Hyacinths.

Acknowledgment of Seed or Plant Orders.

—Our attention has been drawn to the fact that several seed and nursery firms do not acknowledge the receipt of orders or remittances sent to them through the post. We must confess that this comes as a great surprise. It often happens, of course, that goods ordered cannot be despatched for a week or two, or even longer, and the customer is naturally anxious to know that the cheque or postal order has been received. We know it is the custom of most firms to send a formal acknowledgment card of orders and remittances received each day, providing the seeds or plants cannot be despatched at once, the full receipt being sent when the transaction is complete. Neglect of these elementary principles of business is bound to recoil, sooner or later, on those firms which are responsible.

Deterioration of Carnations.

—In the *Carnation Year Book* just published by the Perpetual Flowering Carnation Society there is an interesting contribution on the deterioration of Carnations by Mr. Montagu C. Allwood, who writes: "The great epoch-making Carnation of all past times, Mrs. T. W. Lawson, which bloomed for the first time as a seedling in September, 1894, is to-day but a memory, and why? Simply because

CHIONODOXA LUCILIA NATURALISED UNDER TREES.
THE FLOWERS ARE BRIGHT GENTIAN BLUE.

drills before sowing such fleshy seeds as Peas, covering them with similar compost after they are sown. The covering need only be half as thick now as it would be a month or six weeks hence.

Muscari botryoides as a Pot Plant.—We often wonder why a few pans of this and its white variety *alba* are not more frequently potted

ing little vases of a colour which is generally welcome because it is so uncommon. The well-known Heavenly Blue is just as good as the ordinary *M. botryoides*, but it is a little later to flower, and, as might be expected, its blue is deeper.

Two Good Late Hyacinths.—Those who wish to prolong the Hyacinth season in the greenhouse

sell for the past nineteen years it has grown incessantly without a dormant period, its kind have been propagated from cuttings, not seed. Think of the millions of cuttings which have been propagated from that first seedling plant, and then do you wonder, does anyone wonder, why Mrs. T. W. Lawson is to-day but a shadow of its former self

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Erica carnea on Limestone.—*Erica carnea* thrives very well here, though the soil is limestone. It flowers profusely for a long time, and has done so well that I have been intending to get *E. c. alba* as well.—A. C. KIRKPATRICK, *Donacomper, Celbridge, County Kildare.*

—*Erica carnea* flourishes on limestone soil here, and is now in full bloom.—L. LANE FOX, *Hope Hall, Bramham, Yorkshire.*

Lachenalias as Room Plants.—I have pleasure in sending you the enclosed few spikes of *Lachenalia Nelsonii* for your table. It seems a pity that *Lachenalias* are not more popular than they are at present, for one rarely sees a plant in a shop window for sale; nor have I come across any amateurs attempting their culture. They are easily grown, for if potted up in August in good loam and leaf-mould and put in a cool frame or on a shelf of a greenhouse, they come on quite naturally, and flower at a time when pot plants are most welcome. I usually put four to six bulbs in a 5-inch pot.—F. LANSDELL, *Inglewood Nurseries, West Moors, Dorset.* [The *Lachenalias* sent by Mr. Lansdell were the finest we have ever seen, hence we asked him to send us a potful for photographing, which he kindly did. This is reproduced herewith.—ED.]

Pruning Rose Reve d'Or.—Close to where I write is a very fine plant of this *Noisette* growing against the south front of a dwelling-house, where it has been to my knowledge the last twenty years. Viewing this plant yearly and under various tenants, there never was a better example of good and bad pruning of the variety, with attendant results, than in this case. One tenant who understood the requirements of the variety pruned the previous season's shoots to within an eye or two of their base, with the result that he had freedom of growth and abundance of high quality flowers, enhanced as they were with the copper-tinted foliage so characteristic of the variety. This tree, covering a spread of 20 feet long of the southern front of the house and about fifteen feet from the ground, under these favourable conditions was especially attractive. The next tenant, not understanding the variety, never pruned the plant at all, except cutting away a branch hanging in the way. The result was each year a number of small, puny flowers, quite pale in colour, a mere apology for the true blooms of *Rêve d'Or*, which, when well grown, is still one of the most useful Roses sent out by Pernet-Ducher.—E. M., *Hants.*

Carpenteria californica in Ross-shire.—I observe in THE GARDEN of January 10 that *Carpenteria californica* has been "noted in good health as far North as Perthshire, growing in a sheltered position on a rockery." This plant has flourished for about eighteen years in Lochbroom, on the West Coast of Ross-shire, which is more than 150 miles north of Perth. Two plants of this shrub were planted early in the nineties, but succumbed to the cruel frost of 1895, when the

greatest cold ever registered in Scotland was experienced in some districts. In 1906 two more plants were bought, and one of these is now some five feet high, and bears its beautiful white blossoms abundantly. Within the last ten years the thermometer has twice fallen to zero; but a large cotton dust sheet thrown over the plant has saved its life. Prolonged severe frost without the protection of snow would doubtless have killed it, as was the case in 1895. It grows in a somewhat damp, deep soil, protected from north and east winds by a high wall and hedge. On the occasion of a local wedding in July, 1908, it was observed that some of the estate employés wore in their button-holes the white, star-like flowers of *Carpenteria californica*, probably the first time that this flower had been worn by kilted Highlanders.—A. F.

Peat Moss Manure.—For the last twenty-five years or thereabouts I have used peat moss manure—scores, indeed, I may say, hundreds of tons—for all purposes, on grass land and in the kitchen and

A BEAUTIFUL POTFUL OF LACHENALIAS. THESE ARE EXCELLENT FOR THE DWELLING-HOUSE.

flower garden, fernery and rockery; and I can confidently say that I cannot call to mind a single loss or catastrophe which could be laid at the door of peat moss manure. I could give you proofs to the contrary, viz., to the good effects of it, but I am afraid of encroaching too much upon your valuable and justly popular pages. I have used it at all seasons and in all ways, sometimes fresh from the stable or nearly so, sometimes after lying by for months until wanted, sometimes as a top-dressing, at others dug or trenched in. I have just ordered another truckload of four tons.—W. SERJEANTSON, *Acton Burnell Rectory.*

—The correspondence re peat moss manure is interesting. Perhaps my experience may interest your readers also. When forming a new kitchen garden here, the site selected was a part of the game coverts, and contained a number of Oak trees and the usual undergrowth,

such as Alder, Ash and Hazel. After this was all cut and cleared, it was found that nearly a quarter of the land consisted of peat bog, and those of your readers who are familiar with Surrey bogs will realise the difficulties we had to contend with. All my friends who saw the work in progress said we should never make a kitchen garden of that site, and I got very little support except from my employer, who generously upheld me in my opinions. Some five years have elapsed since we finished the work of trenching, draining (a big item in the bog), path-making and wall-building, and we have never been sorry that we persevered with the task. The first year the crops were not good. This was expected from the acidity and crude nature of the land, it never having previously been cultivated; but in succeeding years there has been very little to complain about, the crops having been good and quality first-rate. I soon found out that Strawberries flourished amazingly in the peat, and strong growers like

Royal Sovereign we have to plant 3 feet apart each way. Even then at gathering-time it is difficult to avoid treading on some of the fruits. Celery, Onions, Leeks and Carrots did not do well the first year or two, but after cultivating the land a few times they grow as well on the peat as in other parts of the garden. At the time we were making this garden the work of demolishing the old residence was going on, and all the old mortar to be obtained was carted to the site and worked in during the process of trenching. Lime works wonders in a peaty soil, and doubtless the large quantity of old mortar which we used went a long way towards making the garden a success. The peat is now slowly losing its original character and gradually becoming a black powdery soil. We get a certain amount of peat moss manure from the stables here, and this is always used for top-dressing. It takes a long time to decay and holds moisture like a sponge, and on this basis I believe it to be most suitable for hot, dry soils rather than for those of a loamy character.—S. W. PHILPOTT, *The Gardens, Anstie Grange, Holmwood, Surrey.*

—I have read with interest the different opinions of eminent readers of THE GARDEN on the use of this manure. I note in March 14 issue that Mr. Bensted anticipates using the manure for *Rhododendrons*. I will give my experience on its use for these. I found here a quantity of *Rhododendrons* planted in an open piece of ground, and looking anything but happy in their surroundings. We selected a piece of ground and had it double-trenched, and a large quantity of this manure was used; also, after trenching, a quantity was spread on the surface, and in this the *Rhododendrons* were planted. The manure was incorporated with the soil in the process of planting. I am pleased to say they are now doing well and showing a quantity of bloom. I have also used the manure in a similar way in making a small Heath garden with excellent results. I may add that the manure was used in a fresh state in both instances.—E. PERCIVAL, *The Gardens, Croydon Hall, Washford, Somerset.*

Viola Jackanapes.—What has become of this distinct kind? I have quite lost it, and cannot find it anywhere.—T. SMITH, *Newry*.

A Little-Known Snowdrop.—I do not think that the beautiful *Galanthus Icaria* is proving as hardy as was generally expected when it was introduced. It is certainly hardier than *G. bifolius*, but it is really not so dependable in the north as we would have expected. For some time I anticipated that it would be quite hardy, and this anticipation was rather borne out by the experience of several winters. In other seasons, however, the handsome arching green leaves suffered from late frosts, with the result that the bulbs did not do much good afterwards. This is unfortunate, as *G. Icaria* is a handsome snowdrop, with large, well-formed, pure flowers, while the broad, green, arching leaves have a size and aspect of their own which renders them specially fascinating. *G. Icaria* comes from the island of Nikaria in the Mediterranean.—ARNOTT.

Acacia dealbata on an Outdoor Wall.—A very fine specimen of this *Acacia* (the Silver Wattle) is now growing on an outside wall in the Newton Glen Gardens, the lovely Hampshire residence of Major Tinker. The tree covers a wall space of 15 feet by 12 feet, but the branches are not trained closely to the wall. The general health of the tree is good, and it has passed through the winter without any special protection. The aspect is a south-west one. On the walls of the mansion, and having a similar aspect, there is a splendid plant of *Cotoneaster angustifolia* bearing the rich orange red berries in greater profusion than any plant I have previously seen. In the same gardens the English Yews are laden with blossom. The trees are grand old specimens, and when Mr. Weaver, the capable head-gardener, shook the branches, the cloud of pollen dust resembled smoke rising from a bonfire.—AVON.

Iris unguicularis (stylosa).—I suppose there is nothing in the hardy plant way in winter-time endowed with so much grace and charm as the German Iris, albeit it is not inclined to give its best if exposed to all the rigours and changes of an English winter. To have flowers of such exquisite delicacy as these possess, however, the plants are well worth protecting—well worth specialising in, it may be—in a sunny frame, so that the protection they need at flowering-time might be given without inflicting any check on the plants themselves. In such a frame the warmth, which is apparently so much to this species, would be more readily forthcoming, while the somewhat earlier growth such conditions ensure should also conduce to an earlier—perhaps also more certain—flowering. In any case the species in all its forms is so good as to merit special care where winter flowers of it are requested. Of most importance, culturally, is the warmth—that of soil, the product of perfect drainage as much as that of position. In connection a limy soil and firm planting should not be overlooked.—E. H. J.

Lavender in Association with Roses.—The notion of forming a carpet to Rose-beds is often rather perplexing. Violas are favourites with many, and in some cases they may answer very satisfactorily. It often happens, however, that the Violas grow too strongly, completely overrun the bed and choke the Rose bushes. Where this is the case, I would advise the use of Lavender. The variety *nana compacta* is excellent for this purpose. It should be planted rather sparsely

throughout the beds. Straight lines should be avoided in planting. Irregular planting gives the appearance of a carpet, and by the exercise of a little care in the arrangement a nice finish can be obtained. If desired, the flower-stalks can be cut off as they appear. This is not necessary, however, as the flowers of the Lavender will associate with most of our garden Roses with perfect harmony. The Lavender grows very dense, and will require lifting and dividing annually, except in the case of large beds, where it may remain for two years if desired.—C. R.

Spiraea lindleyana.—The attention of readers is called to this beautiful shrub on page 82, issue February 14. I should like to supplement the remarks by stating how useful I have found this *Spiraea* for planting on the north side of a wall. Until I had experience with this subject in this position, my opinion was that it was somewhat difficult to manage. In a Hertfordshire garden, where it was planted in good soil and in a sheltered position, it was a complete failure. The reason for this I cannot account for, as it was not damaged by frost; but it did not make any growth, while many other varieties of *Spiræas* near by grew and flowered very freely. In Ireland a small plant grew into a large bush the first season under a north wall. In these gardens a plant in a similar position is most satisfactory. It makes strong growth, and during September is one of the most conspicuous subjects in the garden. This shrub is in ordinary garden soil. Its height is 10 feet. Pruning consists of the removal of weak shoots and the cutting of strong growths back to a good plump bud. This may be done after the flowering season or at the present time.—COLIN RUSE, *Folly Farm Gardens, Sulhamstead, near Reading*.

A White Sport of Saxifraga Boydii.—More than fifteen years ago I reported to THE GARDEN that a specimen plant of *Saxifraga Boydii* which I had planted out on a grave had suddenly yielded white flowers in some parts of the tuft, although the same plant had been in my possession many years previously and had never shown this variation, nor had I ever had the variety alba in my possession before that time. The strangest thing, however, was that with this change to white also resulted the more robust growth of the variety alba, which latter it resembled in every respect. One of your correspondents at that time replied to my note that most probably a shred of the white variety must have been compressed within the cushion, and, released from this pressure through the planting out, had started into growth. This theory did not seem plausible to me at the time, as the stronger growth of the white variety ought to have asserted itself sooner, and now I have proof positive that it must have been a sport. Last autumn I divided a large tuft of the yellow *S. Boydii* into—nearly all—single rosettes, and in this way obtained 250 plants. A great number of those now bear yellow blossoms, but one offset with two tiny rosettes bears on one of these a pure white flower, the other one remaining barren. The plant is too small as yet to be able to judge whether the leafy growth has also changed its character.—E. HEINRICH, *Planegg, Bavaria*.

FORTHCOMING EVENTS.

March 31.—Cornwall Daffodil and Spring Flower Show as Truro (two days).

April 1.—Liverpool Horticultural Association's Spring Show (two days).

SEASONABLE NOTES ON CARNATIONS.

THESE are some things connected with the constitution of the Carnation which are difficult to reconcile. For instance, hardy as we know the plant to be, there are varieties and also sections—the Malmaison and yellow grounds—which would die out were they to be treated as hardy plants, though both have been known to exist, under special conditions, for years in the open. There is the fact, too, that the healthiest layers are produced from pot-grown plants. I refer here, of course, to borders, and the rule is, with those who view the Carnation from the narrowest point, namely, that of a florist's flower and for exhibiting, that they must grow the plants in pots to produce flowers of the best quality.

Raising from Seed.—If we go to the other extreme, the person who has no glass to fly to—not even the tiniest bit of a frame—need not despair of producing Carnations, provided he grows them as biennials and from seed. I daresay those who have always raised seedlings under glass would be horrified at the thought of submitting choice seeds to the keeping of ordinary soil, however suitably prepared, and left to the tender mercies of a wicked climate without any protection whatever. Still, it is true that Carnations do extremely well when sown in the open about this time of the year and treated as ordinary biennials. The point to bear in mind is to cover the seeds very slightly. If in rows, less than half an inch deep will do; if broadcast, pat down the seeds with the back of a spade, but ever so gently, and sprinkle some light material evenly over the whole bed. When the seedlings are 2 inches or 3 inches high, transplant to 12 inches to 18 inches apart, choosing a place where they can be left to flower, though they may be transplanted in the autumn if necessary. It is after propagating stock from selected seedlings that the peculiarities of the Carnation as a partially hardy plant appear.

Perpetual-Flowering Varieties.—The time is near at hand when the early propagated Perpetual-flowering Carnations must be shifted into 6-inch pots from the 4-inch ones in which they have been laying the foundation of handsome plants. The compost from this time should be considerably coarser than has been used hitherto, and crushed mortar from plastered walls must be added in sufficient quantity to render it perfectly porous. The plaster contains a portion of hair, which may serve instead of decayed manure; but a little leaf-soil may be added, provided it is not inert, as so much of it is when reduced by age.

The results of an interesting election of Perpetual-flowering Carnations appeared recently in a contemporary, from which it would appear that a few varieties only are popular, the new Mary Allwood having the greatest number of votes in the novelty section. The name reminds me that Messrs. Allwood Brothers have issued a second Carnation list for the season, in which a selection of standard varieties is given, with the names of those superseded. About one hundred and seventy varieties are named in this list, and then it is incomplete, an indication of how things are going. Mr. Dutton's list, like that just mentioned, is beautifully produced.

Tynninghame.

R. P. BROTHERSTON.

PRUNING ROSES.

(Continued from page 144.)

IN pruning Roses, whether it be a standard or bush, if possible cut to an outward-looking bud. This will give the plant the necessary symmetry, or at least it will go a long way towards doing so. I prefer good, sharp secateurs instead of a knife, but they must be sharp, or they will jag the ends. Cut as close to the eye as possible without actually touching it. The

First Year of Planting, Roses should be severely pruned. Those planted in the autumn and early

growths to develop for next year. Briar Roses, species, Scotch Roses and similar wild-like tribes may be left unpruned the first year, except in the case of a Briar hedge. In this case cut down one or two growths to the base, in order to encourage a thickening of the hedge at the base.

Roses Potted Up in Autumn are pruned fairly hard in early April and allowed to grow outdoors the first summer.

General Hints on Each Group.—Brief notes upon each of the groups may be helpful to readers. These hints refer to established plants. I may here say that when so many inches are given, this refers to the growths made last summer, the first growths, not the autumn shoots. These latter,

tipping its growths. One or two of the stronger growths may be cut back to dormant eyes. Willowmere, Cissie Easlea and Lyon Rose will be treated on the same lines, and Rayon d'Or also where its wood is sound. Juliet, Soleil d'Or and others resembling Soleil d'Or have their young wood retained some 2 feet in length, and, if desired, established plants of Juliet may be pegged down or spread out on a wall.

Hybrid Perpetuals of moderate growth, such as Victor Hugo, prune hard to within 2 inches or 3 inches; the more vigorous, such as Charles Lefebvre, to about five inches or six inches; and the extra vigorous, like Hugh Dickson, as advised for Hybrid Tea J. B. Clark.

Polyantha Roses for edging prune back nearly to the ground line; but if for big bushes, just tipping the shoots is enough. One may have Perle d'Or 12 inches to 15 inches high each year, or, if left alone, 3 feet to 4 feet, very quickly.

China or Monthly Roses.—The common Monthly needs but little pruning, excepting occasionally to cut clean out an old growth or two; but the varieties of Tea origin, such as Comtesse du Cayla, treat as Tea Roses. In sheltered gardens or if on walls they may be left alone.

Bourbon Roses treat as Hybrid Teas. In the Moss, Provence, Gallica, Damask and alba leave the young growths from 6 inches to 12 inches long and freely cut out old wood.

Rugosas or Japanese Roses require little or no pruning, excepting where grown for the display of fruit or seed-pods; then they are best pruned back to about eighteen inches from the ground, and even harder. Conrad F. Meyer is best treated as a free bush, leaving its growths from 3 feet to 6 feet long, or, if on a wall or pillar, to 10 feet or 8 feet long.

Scotch Roses, Austrian Briars, Penzance Briars and Rose species are not pruned, as they flower best on the twiggy shoots; but old wood should be cut out well.

Banksian Roses need no spring pruning. Leave all the spray growths possible. After flowering cut out old growths, but not too severely. These Roses like to have a good roasting on a south wall.

Pruning Special Varieties.—I have already alluded to some, but Frau Karl Druschki often troubles some growers. It is so vigorous, and one wants to know how to use it. If for bedding, I would either peg down the young growths when fit or just dig up the plants in October and plant them again in the same position; then prune hard in spring. This Rose may also be grown on the long pruning plan, *i.e.*, leave the growths from 2 feet to 3 feet in length. This might do in most gardens, but not where Roses are used as bedders. Or one may use Frau Karl Druschki as a climber, planting it and Hugh Dickson upon a fence or wall, and they will bloom splendidly if but moderately pruned. William Allen Richardson answers well as a bedder if pegged down, and it will send up fine growths in late summer that will bear beautiful clusters of bloom in autumn. Other strong Roses of like nature, such as Belle Lyonnaise and Billiard

BLOOMS OF ROSE ENTENTE CORDIALE, A BEAUTIFUL CREAMY WHITE GARDEN VARIETY THAT MUST NOT BE CONFUSED WITH ANOTHER OF THE SAME NAME. (See page 157.)

spring may be pruned by the end of March, but those planted in March and April are best pruned at the time, or immediately afterwards. By pruning hard I mean to within 3 inches or 4 inches of the base of the plants, excepting a few varieties to be afterwards mentioned. Newly planted ramblers of the wichuraiana type should be cut down to within a foot of the ground all save one or two growths to bloom, these to be afterwards cut down in August. By this time young growths will be well advanced from the base to furnish flowering wood for next year. The multiflora group when newly planted are best pruned back to about twelve inches; but if one desires to see a little bloom, one good ripened growth may be retained full length. Recently planted climbing Tea, Hybrid Tea and Noisette Roses planted against walls prune back to 2 feet, excepting the climbing sports of Hybrid Teas, such as Mrs. W. J. Grant, Paul Lede, Marquise de Sinety and Lady Ashtown, which are best retained almost full length if they have wintered well.

Weeping Roses the First Year.—Prune the multiflora group back to 6 inches or 8 inches; the wichuraianas leave unpruned. After flowering, most of the growths of this latter group should be cut back hard, which will encourage new

where very soft and pithy, should be cut back hard, say, to three or less eyes from their base.

Hybrid Teas of moderate vigour, such as Mrs. W. J. Grant, prune to 3 inches or 4 inches; those stronger, such as Mme. Ravary, to 5 inches or 6 inches. In both cases small, lateral shoots are cut hard to within one or two eyes. On the very vigorous Hybrid Teas, such as J. B. Clark, Mrs. Stewart Clark, Sarah Bernhardt and Avoca, retain growths from 1½ feet to 2 feet long, and even longer if desired.

Tea Roses should be pruned the first and second week in April. Leave one growth a good length, even if it has started shoots, which will doubtless be injured by frost, but which will break out again. The other growths prune to good dormant eyes, even to within 2 inches or 3 inches of their bases. Of course, where such Roses are on walls, very little pruning is required, but the growths should be well spread out.

Pernetianas.—This modern group may cause some uncertainty in the minds of readers. Discussing it recently, someone remarked that the frost generally did the work for us; but this is not so with some kinds. For instance, Arthur R. Goodwin is quite uninjured by frost, and I am going to treat it on the moderate pruning plan, merely

et Barré, answer well if treated thus. I love to see these so-called Climbing Teas and Noisettes grown as single specimens, where their growths bend over and are covered with flowers. They also do well trained as espaliers or V-shaped cordons. In this case they are spurred back as one would a Pear tree, and plenty of bloom results.

Single Roses.—Some of the beautiful single Teas and Hybrid Teas, such as Irish Elegance and Irish Simplicity, are best left unpruned; so also is Gottfried Keller, another gem. This Rose resents the secateurs or knife, and should be partially pegged down. Roses on banks should be thinned of old wood every year, or they soon become unmanageable thickets. It is better to have a few fine young growths covered with showy clusters than a heterogeneous mass of shoots, unless foliage effect be our object; then it may be admissible to let them grow as they will.

DANECROFT.

ROSE-GROWING IN TOWN GARDENS.

THE Dwarf Polyantha or Pompon Roses, though of comparatively recent introduction, have already attained wide popularity, and the town gardener has not been slow in recognising their merits. They are of the easiest possible culture, by no means particular as regards soil, and they flower continuously throughout the summer and autumn months. Equaling the Geranium in freedom of flowering and in effect, far surpassing it in individual charm, it is small wonder that these dainty little Roses are becoming increasingly popular as bedding plants in place of more formal subjects. Their chief use in the garden is for bedding, and the best effect is obtained by massing them together.

For front gardens, where a neat and orderly appearance is usually preferred, these Roses are undoubtedly among the best plants that can be used for the purpose. A number of beds, each filled with a different variety, give a welcome change from the rather monotonous scheme generally favoured. This arrangement has the advantage of being a permanent one, and the Roses when properly planted require comparatively little attention afterwards, though they must, of course, be kept clean. Polyanthas are also useful as edgings to Rose-beds, and with the range of colour now obtainable, there is no difficulty in providing suitable companions for any of the bedding Roses. When used in this way, they should be kept dwarf by cutting them down almost to the ground-level each year. The plants produce fresh basal growths in the greatest profusion, and this method of pruning seems to suit them well. Another way of utilising them is to grow them in pots out of doors; and town

dweller with restricted gardens might well make more use of pots, both for Roses and other subjects.

Those without greenhouses are often chary of employing them because of the difficulty of keeping the pots cool during the hot weather, a frequent cause of failure. When exposed to the sun they become so hot that excessive evaporation, dryness and consequent injury to the roots are inevitable; but this difficulty can be avoided by having a few small stands made, similar to window-boxes on legs, in which the pots may be placed. The intervening spaces should be filled in with Coconut fibre, which will help to keep the pots cool and check evaporation. There are many gardens in which stands of this description could be employed to advantage. Often there is a tiled or cemented approach to the garden from the house, which would look far more attractive if relieved with a few plants of some sort, and Polyantha Roses are as pretty and easily grown as anything that can be used for the purpose. One must, of course, have a sunny and rather sheltered spot for Roses grown in this way, and proper soil for potting is essential. Where only a few are grown, it is best to procure this ready mixed from a nursery. Almost all the Dwarf Polyanthas may be grown successfully in towns.

Some of the best and hardiest are Erna Teschen-dorff, dark crimson; Jessie, crimson scarlet;

A GOOD GARDEN ROSE.

BEFORE the planting season is quite over, it may be of interest to draw attention to a very useful and beautiful garden Rose, viz., Entente Cordiale. Unfortunately, there are two Roses bearing this name; hence, in ordering, it is necessary to mention the raiser's name, M. Pernet-Ducher. The other Entente Cordiale is a worthless Rose, and will, one may hope, soon sink into oblivion. The one illustrated on page 156 is of creamy white colour, and the bush is compact, yet moderately vigorous and very free-flowering. The blooms at all stages are very charming indeed, especially when about two-thirds open, as shown on the right of the illustration. They are fragrant and have long stems, so that they are excellent for cutting. One would like to see this Rose more frequently grown.

A. B. ESSEX.

A NATIVE SPEEDWELL.

VERONICA SPICATA.

ON the mountain limestone hills near Llandudno and in other parts of neighbouring counties this beautiful native Veronica grows wild and flowers in profusion in July and August. The flowers are borne in spikes of bright blue, rising about a foot from the ground. For the rock garden this Veronica is much to be commended. It

VERONICA SPICATA, A BRITISH PLANT FLOWERING PROFUSELY IN THE ROCK GARDEN.

Mrs. W. H. Cutbush, rose pink; Yvonne Rabier, white; and George Elger, yellow. Cecile Brunner, one of the prettiest and most distinct, is less hardy, but makes a beautiful miniature pot Rose. Very pretty effects may be obtained by growing Roses in pots in the manner described. A number of other interesting varieties were mentioned by Mr. H. E. Molyneux in the issue of THE GARDEN dated January 31.

P. L. GODDARD.

will clothe bare corners in either sunny or partially shaded positions, and continues to flower for many weeks. It may be raised from seed sown now, and its cultivation is of the very simplest. Under cultivation this wilding has been much improved, the flower-spikes being stronger and of deeper colour. There are a few varieties in cultivation, of which alba, rosea and hybrida are perhaps the best known.

HARDY HEATHS.

(Continued from page 146.)

It is not given to everyone to possess facilities for the making of an ideal Heath garden such as I have attempted to describe; still, as I have already said, much can be done in ordinary circumstances to introduce a few of the best of each kind in most establishments, more particularly since the fashions in flowers have practically ousted the tender varieties once so common in our greenhouses, these being now principally confined to a few trade growers, who, along with Continental growers, produce a selection of the most useful for winter decorations. Several of the hardy Heaths, however, can be used for this purpose, and although less showy and floriferous, if potted up in autumn will come into flower at a time when, flowers being somewhat scarce, they

cutting with the thumb and finger. It will be found, however, that some varieties will require more care in this respect than others, as in the act of stripping off the leaves the bark becomes damaged. Some propagators prefer to allow the leaves to remain on the cuttings. The prepared cuttings should be dibbled closely into suitable-sized pots, these being filled to half their depth with crocks, over which place a layer of fibrous peat, and then fill the pot to within an inch of the rim with a mixture of finely sifted peat and sand in equal quantities. This should be made moderately firm before placing a layer of silver sand on the top. The pots should then be watered so that the cuttings can be dibbled in with ease, filling up the holes left by the dibble with a sprinkling of dry sand. They should then receive a thorough soaking of water, and be allowed to drain properly before placing them in the position in which they are to be rooted, which may be under bell-glasses if a small quantity only, or,

dwarf varieties, having a somewhat tufted habit, only require lifting and breaking up to increase the stock or extend the plantation. Taller-growing and leggy sorts may be layered by simply pegging down a few of the shoots where they are growing, or a few plants of each may be planted deeply in a light, sandy compost, just leaving the points of the shoots above the ground, when they will root readily and provide a large increase of stock.

When the plants have just finished flowering, they may be cut back slightly to keep them longer in a stocky condition, as many of the varieties, if left without attention, will very soon become straggling and leggy. This must, however, be done with care, for if cut back too hard they will not again start into growth. I find *E. carnea* the most suitable for forming edgings to walks, where it grows freely in our light, sandy soil and forms a much more interesting subject than the

orthodox Box edging. *E. vagans* is also suitable for this purpose, but it gets out of order sooner than the former and does not stand clipping so well.

A Useful Selection.—In giving a few names of the best varieties and their approximate season of flowering, I do not attempt a full list, as this can be had pretty correctly from nurserymen's catalogues, but confine myself to a few of the most distinctive sorts which I have found to thrive well under ordinary conditions. The first to open its flowers in the New Year is usually *E. multiflora*, growing about two feet high and having pale red flowers. *E. arborea*, with white flowers and forming large bushes; and *E. codonodes* or *polytrichifolia*, a beautiful pure white with pale green foliage, attaining a height of 4 feet, are also in flower in January if the weather is favourable. During February and March we have that free-growing and free-flowering dwarf variety *E. carnea* and the white form usually sold under the name of *E. herbacea alba*. *E. carnea* is worthy of special mention, and some idea of

THE EARLY-FLOWERING ERICA CARNEA. THIS HEATH BLOOMS PROFUSELY FROM FEBRUARY TILL APRIL.

will be much appreciated for greenhouse and room decoration. *E. carnea* and *E. herbacea alba* are eminently adapted for this purpose. Coming into flower early in the year, *E. mediterranea alba* is another variety which succeeds well as a pot plant, as also do *E. multiflora* and *E. codonodes*, while several varieties of *E. vulgaris* are well adapted for the same purpose.

Increasing Heaths.—Propagation by seeds is not in general practice unless for the raising of hybrids, and the process is naturally a slow one. Raising a stock from cuttings also takes a considerable time, but is found necessary for increasing the stock of any new or rare variety. This can be successfully accomplished if half-ripened shoots of the current year's growth are used; these are made about two inches long. The best cuttings will usually be found in the small, wiry growths towards the base of the main shoots. They should be cut across with a sharp knife, and the leaves stripped off from the lower half of the

if in large quantities, a close-fitting frame will be best. Place the pots on a bed of coal-ashes where a temperature of 50° to 55° can be steadily maintained, keeping the frame as nearly airtight as possible. The cuttings should be shaded from the sun, and in giving additional waterings a careful watch must be kept for condensed moisture on the inside of the glass lights. This must be wiped off as it appears, or the drips will cause damping. These conditions must be followed until the cuttings are rooted, after which air must be very gradually admitted, and the young plants exposed to more light to get them hardy enough to be transferred to cold frames. As I am now dealing with tiny rooted plants, the next operation should be to plant them in lines in a cold frame, where they may remain for a year at least before being put in the open ground. When, however, a good stock of plants has been once obtained, this slow method of propagation may to a large extent be dispensed with. The

its manner of growth and the great freedom with which it flowers may be obtained from the accompanying illustration. Covering the period of March to May the principal varieties in flower include *E. mediterranea*, another dwarf variety in red, pink and white shades. A tall-growing sort under the name of *E. m. multiflora* flowers in August; this is a very distinct variety, having white flowers, with prominent chocolate-coloured anthers. *E. australis* and *E. Stuartii* are generally in flower in the month of June, the former, about three feet high, having purplish red flowers, and the latter, a neat, dwarf-growing plant of 6 inches, with pretty rose-coloured flowers. A hardy Heath garden, I think, would be incomplete unless it included in the selection some plants of the lovely St. Dabeoc's Heath (frequently alluded to as the Irish Heath, *Menziesia polifolia*), *M. p. alba* and *M. empetrifolia* being good representatives of this genus.

Glamis.

THOMAS WILSON.

THE GENUS ROSCOEA.

COLOURED PLATE 1490.

IN many ways this is a remarkable genus. For one thing it is the only hardy genus in the family of Ginger-worts, a family which includes, besides the Ginger Root (*Zingiber officinale*), such well-known plants as the Banana, Canna and the beautiful-leaved *Maranta*. The genus *Roscoe* was so named in honour of William Roscoe, who died in 1831, after having made a name for himself as a historian and in having founded the Liverpool Botanic Gardens, which are now under the charge of Mr. W. Hackett, late of Kew. Until the discovery of *R. cautlioides* in China by Mr. Forrest, it was considered that the species of *Roscoe* were confined to the Himalayas.

Roscoe sikkimensis (No. 1) although classed with *R. purpurea* by botanists, is quite distinct, as will be seen in the coloured plate. It was found about one hundred years ago, but is by no means common in gardens even yet. Scarcely one foot in height, it produces leafy stems, each bearing several bright purple flowers. The form of the flowers has led many casual observers to mistake them for the flowers of Orchids. The dorsal lobe of the three-parted corolla stands erect, and is usually somewhat hooded. The roots are tuberous and do well in sandy loam, surviving our winters readily when planted 4 inches to 6 inches below the surface.

R. purpurea Bees' Variety (No. 2 in the coloured plate) is a very handsome, well-marked form. Its claim to distinction lies in the boldly enlarged labial lobe, and in the rich wine purple colour.

R. cautlioides (No. 3) is probably the most vigorous of the family. It is certainly one of the most charming of flowers. The colour—a soft delicate primrose, rather full in tone—reminds one of the particular shade of yellow seen in *Meconopsis integrifolia*. As many as half a dozen flowers are produced on each 9-inch to 10-inch stem. It is a beautiful flower, with all the delicate beauty and texture of a Poppy. Found by Mr. George Forrest, in Yunnan while collecting for Messrs. Bees Limited, of Liverpool, it has proved quite hardy in North Wales, and also, we understand, in the gardens of the Royal Horticultural Society at Wisley.

R. alpina is another importation by Mr. Forrest. It is a fine purple and is likely to oust *R. sikkimensis*, being of free growth and very hardy.

The *Roscoe*s are admirable plants for the rockery. Enconced in some well-drained pocket of sandy loam, with ample depth to root into and with plentiful supplies of moisture during the growing season, these rare and lovely plants will give a good account of themselves. A colony of the different sorts, yellow blending with purple, would be enchanting. We are indebted to Messrs. Bees Limited, of Liverpool for the flowers from which our coloured plate was prepared.

SOME GOOD ANNUALS FOR CUTTING.

INEXPENSIVE and easy to grow as are the majority of annuals, some of them stand unequalled throughout the summer for supplying the ever-increasing demand for cut flowers. In some gardens this demand is often the means of spoiling, more or less, the effect that was aimed at when planting. In cases where space is limited, this cannot very well be avoided. But where a convenient plot in the kitchen garden can be set aside for the sole purpose of planting for cutting,

do without any further trouble. In the different varieties of *Calliopsis* we have ideal flowers where lightness in arranging is necessary. Some of the best are *C. Drummondii* (brilliant yellow), *C. tinctoria* (yellow and brown), and a good dark red one is *C. atrosanguinea*. The annual *Chrysanthemum* is now indispensable. Of the many varieties to be had, *C. burridgeanum*, with red and white flowers, is as useful as any. *C. White Pearl* is always admired. *C. Golden Cloud* is well named, as the flowers are a true gold colour. Cornflowers in their various shades are always effective with *Gypsophila elegans* and *G. carminea*. *Clarkias* and *Godetia*, when given plenty of room, make graceful spikes of bloom that are not to be

despised. *Nigella*, white and blue, is a general favourite. The Sweet Sultan in different colours is well worth a place, and for fragrance *Mignonette* is indispensable. Everlasting flowers find favour with many, and in the different colours of *Helichrysum* they are seen to the best advantage. No list would be complete without Sweet Peas, the culture of which is described from time to time in these columns.

Half-Hardy Annuals.—The under-mentioned varieties are half-hardy, and should be sown under glass towards the end of March in boxes of light soil. When large enough to handle, they are pricked out in boxes or frames and kept steadily growing until about the middle of May, when they are gradually hardened off, to be planted out when all danger of frost has passed. Asters of the single and Comet type, with the variety known as Ostrich Plume, are light and graceful, and the best for cutting. The tall-growing *Ageratum mexicanum* provides a quantity of blue flowers. *Cosmea* is a desirable race of free-flowering plants, in colour white, rose and crimson. *Nemesia*, though usually regarded as a true bedding plant, is very effective indoors. *Salpiglossis*, owing to its magnificent colours, has no equal among its class. In Webb's strain known as Harlequin it is seen at its best. *Phlox Drummondii* is none the less admired when cut. Stocks, for their delightful fragrance, are essential to every garden in the summer, and when cut are never out of place. Apart from the necessary hoeing and weeding, with an occasional watering in very dry weather, all the above are of the easiest possible culture, and will flower freely until the colder nights put an end to outdoor growth.

F. G. TOWNEND.

The Gardens, Brentwood, Moorgate, Rotherham.

LILIUM NEPALENSE, A BEAUTIFUL ORIENTAL LILY WITH CITRON AND PURPLE BLACK FLOWERS.

it will be found most agreeable and convenient. In such a position, or wherever annuals are to do themselves justice, the soil must be made suitable by good digging and manuring in the proper season. Previous to planting or sowing, it is an advantage to thoroughly break up the surface with a fork, and on the first opportunity after the soil has got in a workable condition make the surface fine and level with an iron rake.

Varieties for Outdoor Sowing.—The following varieties are hardy, and may be sown where they are intended to bloom, and, as soon as large enough, thin out to prevent weakness through overcrowding. This is most essential if the plants are to make sturdy growth and flower as they should

LILIUM NEPALENSE.

If *Lilium nepalense* were only a little hardier, it would doubtless be the most popular of all the Oriental Lilies. It has been successfully grown in the open in Devon and Sussex, but, speaking generally, it should be given cool greenhouse treatment. The beautiful reflexed flowers are very striking in appearance, being citron yellow towards the edge, with deep maroon purple or almost black within. It was introduced in 1855 from the Central Himalayas.

DAFFODIL NOTES.

NOTABLE VARIETIES AT THE FORCED BULB SHOW.

THE two flowers that were most talked about were Queen of the West, which, as I said in my last notes, for the first time in its life sought the suffrages of the buying public; and a glorious deep yellow Ajax of giant size, which for a long time blocked one corner of the eastern annexe with people eager to get a glimpse of its noble proportions. Dinton will know it no more. As Magnificence it will find a new home in the grounds of the Donard Nursery Company in County Down. Mr. Engleheart told me he had gathered it from the open a day or two before the show (March 10 and 11). It would be a striking flower, because of its size, deep colour and the exceptionally wide recurve of its brim, at any season; but blooming as it does so early, its merits become the more pronounced. Diameter of whole flower, 4 15-16 inches; diameter of trumpet, 2½ inches (width of roll of brim, five-eighths of an inch); length of trumpet, 1½ inches.

Queen of the West, the other variety that I have already mentioned, is a large flower of a soft lemon yellow, quite a self. The trumpet is bold and impressive, but the perianth always seems to me to be a little too much on the floppy side and to give the flower a hooded look. This little defect, if defect it be, is more than counterbalanced by its strong stem and superb colouring, which is even more pleasing under electric than under natural light. Those of us who were present at the Horticultural Club dinner on the first day of the show had a good opportunity of judging, as all the tables were decorated with vases of Queen of the West. I imagine it wants a warm, well-drained soil to do itself justice in the garden.

Almost all the varieties that I am about to mention are old ones. Naturally, this must be the case, for I do not think high-priced novelties are what we want at a forced bulb show; rather, those well-tried old sorts which we are finding out lend themselves to pot work. Thora (Walter T. Ware) is one of these *par excellence*. The beautiful tone of gamboge in its short trumpet, which gives the bloom its prominent characteristic, is only brought out when it is grown under glass. Eoster as I saw it in Mr. Christopher Bourne's group looked exceedingly chaste. I have never tried it in pots myself, but as Mr. Bourne assured me that it is splendid for this purpose, and as the proof of the pudding is in the eating, I feel I can give it a commendatory note. Out of doors it is none too robust. Aquarius is a nice, tall-growing Leedsii, with the edge of its cup speckled with yellow and apricot. Some remarks which I overheard were not very favourable; others denoted that the makers thereof were impressed. The idea is rather far-fetched, but I imagined this quaint marking made the flower a little like the old alba regalis of the Tulip kingdom. Felspar (3½ inches by 1½ inches by 1½ inches), also on Messrs. Cartwright and Goodwin's stand, looked very well indeed. Another Giant Leedsii, Capella (3 inches by 1½ inches by 1 inch), as pretty a flower as anyone need wish to see, was in fine form on Messrs. J. R. Pearson and Sons' stand. Three blooms were perfect. The neat, rounded-looking segments and the well-shaped small trumpet were almost of a uniform ivory white, and the

whole seemed to possess that substance and rich-looking appearance which are synonymous with high quality. I am beginning to call my friend Duncan Pearson's Leedsii the cut-and-come-again strain. First Norah Pearson, now Capella.

Cheek by jowl on Messrs. R. H. Bath's stand were Brilliancy and Flame. Both may be pictured if I say they are glorified Barri conspicuuses. The latter variety is the best and most striking. Its perianth is yellower, and its cup longer and wider than in the older flower, and the whole is larger, the diameter of the perianth being 4½ inches, and of the cup 1 inch. I must couple with this Sparkler, which was in Messrs. Barr and Sons' collection. It is one of the best of the very early red cups.

A pretty double of an uncommon shade was to be seen in Mr. W. T. Ware's small and select group in the flower named Sun Tints. Buff segments and transformed stamens, with orange bits of nectary scattered among them, is its colour description, which, added to the fact that the flower is a good 4½ inches across, and that the divided-up perianth is more regularly deposited than in many doubles, enables us to form some idea of the whole. Sweepstake, which was tucked away in a corner among the blooms of Messrs. W. B. Hartland and Sons, was very striking. It has a great deal of the look of Heroine; in fact, when Messrs. Pearson's head man and myself took a vase of the latter over to compare it, he said he had no idea that there was a flower in existence so much like it. The perianth is smoother and possibly not quite so white, and the cup is larger and with a more clearly defined red edge. Otherwise the two varieties are very similar. I have no idea what sort of a doer Sweepstake is, but it is certainly one to ask about. Silver Glade, a triandrus hybrid, is pure white, with a cup-shaped centre; Queen Mab, a fine bicolor seedling from Penzance; Northern Queen, a delightful pale peerless; minicycla, the tiny minimus x cyclamineus strain of Mr. Herbert Chapman; Hercules, a sort of more refined and yellower Olympia, which was a new purchase by Messrs. R. H. Bath; Inglescombe, a sort of lemon-coloured double Begonia; Florence Pearson—everyone said "how good," but I wish I could have transported a couple of blooms from my greenhouse, just to show what it sometimes can do; Mikado, a spidery-looking yellow Ajax with a twisted, narrow perianth and an expanded trumpet, very early; Lady Margaret Boscawen and Homer (the latter I always find much better than Horace in pots); Alabaster, a beautiful triandrus hybrid, and a potful of another in Mr. Chapman's lot of which I forget the name, but which is easy to distinguish because of its delicate greenish primrose colour, which I am told Mr. Engleheart says can only be obtained from a cross between King Alfred and calathinus.

JOSEPH JACOB.

ORNAMENTAL GRASSES FOR CUTTING.

THERE are many beautiful grasses that may be sown now in the open ground. From midsummer onwards they will be found of great value for mixing with other cut flowers, or, if cut before they are fully developed, they may be dried, when they will be found excellent for mixing with everlasting flowers for winter decoration.

THE GOOSEBERRY SAWFLIES.

THE caterpillars or larvæ of the Gooseberry sawfly are extremely destructive in some gardens during the summer, and quite frequently I have seen healthy bushes entirely denuded of foliage by their ravages. The larvæ, after having gorged themselves, pass down into the soil round the bushes and hibernate there, to emerge the following spring and multiply with astounding rapidity. The gardener who had trouble with them in the previous year may rest assured that they will attack his bushes again, probably in greater numbers than ever, and he should set about putting into practice remedial measures, even though there is not the faintest suspicion of any pest at present.

A good fumigant hoed into the soil during the month of April will account for many of them. Even gas-lime not too fresh may be used, but only lightly worked into the soil; and of the very highest efficiency is road grit containing tar products, which may be spread as a thin mulch over the surface and kept there all the year. The tar, unless present in obvious excess, will not injure the bush in any way.

At times during the month of May the gardener may spray the foliage with an insecticide, as evil-smelling as possible, in order that the flies may be prevented from depositing their eggs on the leaves. Naturally, this may continue until the time for gathering the crop is approaching. It is really wonderful how much can be done by timely preventive work; but if it is neglected until the bushes are alive with the destructive caterpillars, only the most strenuous efforts and the most poisonous preparation will have any appreciable effect. Do not fancy that because the larvæ do not touch the fruit they are beyond consideration. Crops cannot be satisfactory or be of much value under the circumstances, for the leaves are the stomach of the plant, and as such are necessary for its well-being, and even for its existence.

H. H. A.

APPLE ROUND WINTER NONSUCH.

THIS is one of those good old Apples that many years ago were planted more extensively than is the case at the present time. The trees bear very freely and regularly, while the Apples keep sound till March. The fruits have a bright, beautiful crimson colour on the side exposed to the sun, and, although a cooking Apple, medium-sized fruits taken from aged trees are very passable for dessert. I have grafted other less useful Apple trees with this, and am well pleased with the fine fruits yielded during the past few seasons.

APPLE BAXTER'S PEARMAIN.

SOME few years ago I had a few grafts of this Apple sent me by a friend I noticed exhibiting nice dishes of fruits at the Royal Horticultural Society's Hall. The fruits on that occasion were very firm and of nice size. My trees have borne crops for two years, and I find that if left hanging rather late, the fruits keep very sound till March. Although the flavour and flesh are not that of Cox's Orange Pippin, there are many worse Apples grown than Baxter's Pearmain, and anyone planting a few trees will not have much room for regret when once the trees are of fruiting size.

H. MARKHAM.

GARDENING FOR BEGINNERS.

MY SMALL ROCK GARDEN: HOW I MADE AND PLANTED IT.

WHY should not the "alpine" enthusiast make his or her garden, however small, into an alpine garden altogether, and cultivate therein the immensely varied forms of mountain plants which are available, and which, by judicious selection and careful planting and attention, gladden him from January to December? It is now some years since I essayed this congenial task; and since it has produced such a fund of pleasurable enjoyment and healthy exercise, perhaps a rapid outline of my procedure may induce others to extend their rockery upon the same lines.

Choosing a Site.—When one's ground measures, let us say, 100 feet by 50 feet, it is little use brooding over which portion of our domain we shall devote to the alpine garden; and, providing there are no overhanging trees and two-thirds of the space receives a fair amount of sunshine, it is quite possible, as in my own case, to devote the whole to the scheme in hand, and, what is more, decoratively furnish it in every part.

The Building Material.—The next problem which confronts the rock gardener is building material. I would like here to emphasise the fact that usually the man with a small garden often has the added disadvantage of a shallow pocket, and however desirable it is to employ the most perfect material, such as mountain limestone (and no one appreciates more than I do the decorative value of beautiful stone), it is often beyond the range of the gardener to obtain such for a reasonable outlay. Anywhere in my neighbourhood such stone will cost from 15s. to 20s. per ton by the time it is delivered, and supposing that thirty tons are needed, the cost is often prohibitive. Writers of considerable experience often suggest that real stone is necessary for the successful cultivation of alpine plants. While the term "success" is, I agree, a difficult one to define, I do, with all respect, emphatically differ from them, and, so far as my experience goes, nothing is so likely to turn the "would-be alpinist" from his project as too much emphasis on this particular. My own garden shows that it is easily possible to cultivate, with a very considerable degree of success, the great bulk of alpine plants, including many of the choicest, without a particle of real stone; and I should strongly urge those who are placed as I am to employ the concrete lumps frequently obtainable near London, and which, I believe, come from beneath the City roads when the latter are being relaid.

Having decided upon the matter of "rock," the next item is soil. The garden in question will doubtless furnish some amount, especially if it is decided to lower one portion of the ground so as to increase the height of the slopes and possibly

form a pool, by the margin of which many water-loving plants will find a congenial home. This can be augmented by a few loads of loam and more of sand—even if the latter is only sweepings from gravel roads. A quantity of builders' refuse is also a very great help, and the coarser portions of this latter can with advantage be spread over the site to act as drainage, should the natural soil, as in my case, be of a close, clayey nature. Having heaped the earth (after well mixing) in the varying masses we wish the design eventually to take, and having decided where the main paths are to be, it is well to start at the lowest point and begin building.

When several are in position, well pack the gritty soil behind them so as to make all firm and solid. After roughly levelling, proceed to place the next higher tier. While a rock bank must be more or less in the form of terraces rising one above the other, care must be taken to avoid formality and to vary the outline by employing blocks of various shapes and sizes; while often a good effect can be secured by breaking across a terrace with two pieces lying at an angle. Arrange for the ground to slope at varying degrees of steepness in different parts. Where a gentle incline is being formed, it is frequently possible to secure an excellent effect by allowing a promontory to jut

VERONICA RUPESTRIS FURNISHING THE PATH EDGE.

Making the Paths.—Every effort should be made to make the paths as irregular as possible, both in the horizontal and vertical direction, thus getting as far as possible from the formal, though care should be taken to make them sufficiently wide to avoid damage to the plants which will eventually mantle the rocky slopes adjoining. Where the path dips, it is better, I think, to form it in a series of steps.

Placing the Rock.—To return, however, to the building. The first thing to do is to well ram the seating, and at the same time give a slight inclination inwards and towards the bank of soil, at the base of which the work is being started. Upon this spot place the first "rock" in such a way that it lays firmly and also has its most decorative face outwards. Next to this put block No. 2, locking them together by their projecting ends, so as to leave no space between them through which the soil will leak, or, failing this, stopping the opening with a smaller piece

out, as though an extra large outcrop was emerging there.

Where the rock bank slopes to the path, arrange for it to fall in a steep buttress in one place, as though a strong shoulder was holding up the mass; then, after making a little bay or inward curve from the path, to come forward again, this time as a more gently rising spur. When viewed from a little distance, the slowly rising buttress will show up in pleasing contrast to the more vertical one. Always use the most select pieces of stone for these promontories, since they can well be left less draped with verdure than the remainder, and so give force and character to the whole. Each stone, no matter what its size, should be so firmly placed and wedged as to be immovable if stood upon, while the earth must always be well rammed behind to form a solid foundation for the higher parts to rest on.

REGINALD A. MALBY

(To be continued.)

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Late Vineries.—All late Vines will be well on the move now, and should not be subjected to much fire-heat; 55° at night will be quite high enough. When the buds become prominent, the Vines should be carefully tied to the trellis, and disbudding accomplished as soon as it can be ascertained which are the most promising. Very little air will be necessary for some time, and this should be admitted early in the day, shutting up the house early in the afternoon to secure a good rise of temperature by sun-heat. The walls and border may be syringed several times daily to promote a moist atmosphere. The temperature of

Muscat Vineries should not be allowed to fall below 70° at night, especially during the flowering period, and at this stage the atmosphere must be kept moderately dry and the pollen dispersed by means of a bunch of soft feathers or a rabbit's tail tied to a light stick. The trellis should also be shaken several times during the day. When a good set has been secured, the border should be examined, and, if necessary, a good watering of clear water given.

Plants Under Glass.

Chrysanthemums.—The early struck plants will now be established in 6-inch pots, and should be given as much air as possible during favourable weather to keep them from becoming drawn. Remove the lights during mild days and replace them at night. Watering must be carefully attended to, giving the plants a good soaking of clear water when necessary. There is nothing more detrimental than frequent dribbling with the water-pot when the soil is neither wet nor dry.

Carnation Souvenir de la Malmaison.—These plants will now require a little shade during the hottest part of the day. Never allow them to suffer from want of water at the roots, and feed them frequently with some approved manure. Young plants should be grown in cool quarters, no fire-heat being necessary. Keep a sharp look-out for aphids, and fumigate before it becomes established.

Sweet Peas in Pots should now be ready for their final potting. Make the soil firm about the roots, and place the plants in a well-ventilated house and fully exposed to the light. When established, frequent waterings of liquid manure should be given.

Winter-Flowering Pelargoniums.—For this purpose young plants should now be ready for potting into 4-inch pots, and when they become well rooted the tops should be pinched in order to produce bushy plants. Do not allow them to become stunted for want of root room, but pot again as soon as necessary. The soil may consist of two-thirds turfy loam and the remainder of leaf-soil, and this should be made moderately firm.

The Flower Garden.

Sweet Peas raised in pots for planting in the flower garden should be exposed to the weather for eight or ten days before they are planted in the open. The ground for this purpose should be thoroughly trenched and manured if the best results are expected, and protection from rough wind must be provided by placing evergreen branches round the plants as soon as they are put out.

Violas and Pansies.—These should be planted out with as little delay as possible. If raised from autumn-struck cuttings and wintered in cold frames, they should be nice stocky plants now, and, if carefully transplanted, may be expected to flower freely in April and May.

Calceolarias in Cold Pits.—The leading points should be carefully pinched out in order to produce numerous side shoots. If space is available in a cold pit, they will benefit by being transplanted into finely sifted soil, allowing a space of 9 inches between the plants.

Seedling Bedding Plants.—Antirrhinums, Pentstemons, East Lothian Stocks and other seedling plants should be pricked out as soon as large enough to handle. Place the boxes in gentle heat until the plants have recovered from trans-

planting, after which they may be grown in a cold frame; but protection from frost should be provided.

Propagation of Bedding Plants should be finished as quickly as possible, either by seed or cuttings, as the time is approaching when many of them will require hardening off. Lobelias may still be raised from cuttings. Carpet bedding plants may be rooted in boxes, where they may remain until required. If large quantities of Alternanthera are required, a hot-bed may be made up for the purpose and covered with finely sifted soil to the depth of 4 inches. The cuttings may be inserted in this, and will quickly make roots; but care must be taken that the heat is not too strong.

Hollyhock Plants which have been wintered in cold frames should be planted out as soon as possible. If grown in large clumps, they form very conspicuous objects during the summer and autumn.

The Kitchen Garden.

The Sowing of Seeds.—The heavy rain so far experienced during March has seriously delayed the sowing of many small seeds; but, although rather late, it is better to defer sowing for some time longer than to trample on the ground while wet, especially if the soil is of a heavy nature.

Potatoes.—The planting of early varieties should be finished as soon as possible. If the tubers have been started in boxes, it is necessary to plant very carefully, or some of the young shoots may be broken. Sufficient space must be allowed between the rows to allow light and air to pass freely among them. The planting of second-early varieties may be pushed forward, covering the sets with 4 inches of fine soil. It is very important that all tubers for future plantations should be laid out singly, so that the young shoots may not become drawn, and for this purpose a well-ventilated shed should be chosen.

Celery.—If seeds were sown in February, the plants should now be ready for pricking into boxes of fine rich soil. If space is available in cold pits, the young plants may be transplanted into these, allowing a space of 6 inches between them each way, so that a good ball of soil may be lifted with each plant when they are placed in the trenches.

Beet.—A sowing of Globe Beet may now be made in a sheltered spot for the supply of roots early in June. Sow in drills a foot apart and cover with an inch of fine soil. Beet in store should be frequently examined and all young growth removed.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Peas.—From now the main crop of Peas may be sown, and to keep up a succession it will be a good guide to sow as soon as a former lot has come through the ground. The taller and larger-podded varieties will require to be sown much thinner, and also allowed more room between the rows. Perhaps the best way of securing a constant supply of Peas of the best quality is to break up the other crops with an occasional row. This will provide a shelter to the lower-growing subjects, and at the same time enable the Peas to get well developed.

Seakale.—The smaller roots secured from crowns before forcing may now be planted out, and this on ground that has previously been well manured. If these roots were placed in a cool house as advised some time ago, growth will now be started. As in the case of sprouted Potatoes, it will be well to reduce the sprouts to one before planting.

Turnips.—Continue to make a sowing of some of the earlier varieties, and, as in former sowings, give the ground a good dressing of lime, which will assist to ward off the fly that proves so troublesome in the seedling stage.

The Flower Garden.

Violas.—If flowers are removed from the young plants until they are established, they will continue blooming throughout the year. At Hopetoun we grow many thousands, chiefly of the variety

Come to Stay, which are used to carpet the ground under Roses. The effect is very striking indeed. It would not, of course, be wise to plant them among choice Roses, or where they are required for exhibition purposes; but for ordinary decorative varieties there is much to admire in this style of decoration. The Viola I have mentioned seems to stand the drought better than any other variety I know.

Annual Lupines.—These are now regarded as one of the most popular hardy annuals of recent years, well deserving a prominent place in any garden. As they do not bear transplanting, they must be sown where they are to flower. To ensure that the young plants will not suffer from slugs just as they are coming up, I find it a good plan to sift some fine soil and ashes, and place it on the border where it is intended to sow them. The seed may be sown now very thinly, and afterwards thin out well, as each plant will make a fine specimen. Hybridus atrococcineus and mutabilis, cream and white, are two of the best, and will be found to be invaluable for cutting.

Melanthus major.—This handsome subtropical subject, so useful as a dot plant in the flower garden, and possessing as it does such beautiful Fern-like foliage, never fails to attract attention. Seed sown now in small pots and grown on in a little heat will make fine plants by the beginning of June, which will be soon enough to risk planting them out.

Pruning Shrubs.—A start may now be made with the pruning of evergreen shrubs, such as Laurels and Yews; but it will be wise to defer interfering with Box trees for some time yet. The pruning of Laurels should, as far as possible, be done with the knife.

Plants Under Glass.

Tuberose.—Bulbs should be potted as soon as they arrive, as they are so liable to damp if kept any time in bags. The small bulbets should be rubbed off before potting, for as the bulb is of no value after the first year, there is nothing gained by retaining these. After potting, place them under a stage, where they may be covered with a little loose hay, which will prevent the soil becoming dry. They should be brought on in batches as required, and as soon as growth commences keep them close to the glass, otherwise they are inclined to grow rather tall.

Winter-Flowering Carnations.—Early rooted cuttings which have been stopped will now require repotting, and should be placed in a cool house; indeed, they may be kept in this house all the season, provided one is assured of sufficient light and air. Many growers place them in frames or out of doors during the summer, chiefly in the South; but in the less congenial climate of the North I think this is a mistake. Stop all shoots that may run to bloom until June, which in the Northern Counties will be found to be late enough. Where one has an old house at command, one can grow a batch on the bench system, and, if not stopped after this date, they will give a fine supply of flowers in early November. These benches or boxes need not be more than 6 inches deep, and a sufficient length so that they can be moved when not in use.

Cœlogyne cristata.—In many cases this useful Orchid will have passed out of bloom, and will claim attention in removing some of the oldest of the pseudo-bulbs, and, in a few instances, repotting. This Orchid resents being disturbed at the roots, so that established plants should not be disturbed unless absolutely necessary. When growth commences, give liberal supplies of water, and later on liquid manure may be given, though only in a weak form.

Fruits Under Glass.

Vines.—As growth advances, a light sprinkling of some good Vine manure may be applied to the border from time to time. This will be readily taken up where the roots are near the surface. Fruit on pot Vines will be nearing the colouring stage, and a little more air may be admitted. Exercise great care in watering to prevent splitting. Vines coming into flower will require a mean temperature of 60° to 65°, allowing it to rise 15° with sun-heat. During this period the house should be kept somewhat drier during the day. Muscats must have a higher temperature when in bloom.

Hopetoun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON VEGETABLES.

Onions.—For general use the main crop of Onions is distinguished from exhibition bulbs by the fact that they are grown entirely in the open. The month of March is the general time for sowing the seed. The ground will have been heavily manured and dug in the autumn, and left in as rough a state as possible for the wind and frost to pulverise the surface. Give the plot a dressing of wood-ashes, soot, lime and road grit if the natural soil is of a heavy, tenacious character. Choose a dry day to fork over the surface 6 inches deep, breaking the clods as the work proceeds. Allow it to settle down for a few days. Choose again a dry day to rake over the surface, removing the large stones and any rubbish. If the soil is light in character, tread the surface firmly over and rake again before sowing. Draw shallow drills with the corner of a hoe, sow the seed, and cover with a compost of wood-ashes, soot and old potting soil, with a handful of lime added. This addition, where the soil is heavy, is an inducement to quick growth. With the heels fill in the drills and rake evenly over. Exhibition Onions should be now well hardened off in cold frames, inducing the growth to be made as sturdy as possible. Prepare the site for planting, as the weather permits, by spreading soot, wood-ashes and lime over the surface, lightly forking the soil over in dry weather, and thus, as opportunity occurs, planting may proceed as quickly as possible. With a trowel take the plants out of the boxes with as large a ball of soil as possible attached to the roots. Allow 15 inches between the rows and from 1 foot to 14 inches from plant to plant.

Potatoes.—The main crop should now be got in as fast as possible. This will allow a long season of growth, which is an all-important point, especially if drought sets in in May or June, as is sometimes the case. Those tubers that root early will withstand drought so much better than those more recently planted. The ground will have been previously manured in the autumn and forked over preparatory to planting, which is an incentive to free growth. The best plan is to dig the ground and plant as digging proceeds, with the exception of the late batch, which may be planted in the field or between fruit trees, where the plough will aid planting. To grow good Potatoes, ample space is required to allow of free development of haulm and leaves. One, or at the most two shoots are ample to each tuber. Those sprouted in boxes can be regulated in this by rubbing off surplus sprouts. The midseason sorts should be 15 inches apart in rows 2 feet wide. The later sorts, of which The Factor is a type, need 20 inches of space, or a yard where the soil has been heavily manured. Where the soil is heavy,

cover the tubers with a compost of wood-ashes and old potting soil, with a small quantity of leaf-mould, as this will encourage quick root action and accelerate the growth. Where farm-yard manure is scarce, especially for the late varieties the following is a good substitute, sprinkled over the tubers in the trenches at planting-time per acre: 5cwt. of superphosphate (35 per cent.), 1½cwt. of sulphate of ammonia and 1cwt. of muriate of potash.

Broccoli and the various sorts of winter greens should now be sown in the open, including Brussels Sprouts for a late crop. Sow the seed thinly, covering with fine soil, with which is added a small quantity of soot. Cover the beds with netting to prevent birds of the linnet class devouring the tiny plants the moment they show through

the pots in a cold frame until the plants are well up; then, outside, plunged in ashes, is the best place. This method is much better than either putting in new plants from the open or sowing seed where the plants are to grow.

Parsley.—Plants raised from early sown seed in boxes should now be put out on the borders alongside paths, or in a well-prepared bed in the open if a quantity is required.

Leeks.—The plants raised under glass will now be hardening off in frames preparatory to planting out. The trenches should be prepared ready for their reception about the second week in April. They should be 2 feet deep and 18 inches wide. Break up the bottom of the trench at least 6 inches deep, to allow of free draining of water away from the roots. On the top of this add 4 inches of well-rotted manure. On the manure lay 3 inches of a prepared compost of old potting soil, leaf-mould and wood-ashes, adding to each bushel of the compost two double handfuls of fine bone-meal, well incorporating the whole together. E. MOLYNEUX.

Swanmore Park, Hants.

BOOKS.

An Artist in Garden Planning.*

—In the past architects have often been lacking in sympathy with the horticulturist, but it is now an accepted axiom that architect and gardener should have at least a knowledge of each other's business and endeavour to work in unison. In the case of Mr. Lutyens, Mr. Weaver writes: "One of the important happenings in the career of Mr. Lutyens was his early acquaintance with Miss Jekyll. Her great gift of gardening served as a stimulus to his appreciation, and led him to give the large attention to garden design which he has developed. It would be difficult to exaggerate the importance of her influence. Architects find in gardens a just sphere for design, but they cannot be expected to have a wide knowledge of horticulture. It is in the main to Miss Jekyll that we owe the rational blending of formal and the natural in garden design, which has harmonised the theories

of two contending and often acrimonious schools." The first of the important gardens designed by Mr. Lutyens for an existing house was made in 1893 at Chenies, Buckinghamshire, for Adeline Duchess of Bedford, of which gardens there are many splendid illustrations. The steady progress in the design and general picturesqueness, disclosed in the more recently constructed gardens illustrated in this book, reaches its zenith probably in those at Hestercombe (Chapter IX.). The superb illustrations of "The Great Plat" at Hestercombe, "The Main Terrace and Retaining Walls," "The Rill and Arbour in the Rose Garden,"

* "Houses and Gardens by E. L. Lutyens," described and criticised by Lawrence Weaver; 25s. net. Country Life Offices.

LILY POOL AND STEPS.

(From "House and Gardens, by E. L. Lutyens.")

the soil. As the plants grow, remove all weakly ones to ensure a more sturdy growth for those remaining, and keep the beds free from weeds for the same reason.

Vegetable Marrows should be sown in pots in a frame or gentle heat to get them forward. Plant the first batch under hand-lights or spare pit-lights, which are a protection from frost.

Asparagus should have attention where the beds were covered with short manure. This should be lightly forked over, raking the rough portions into the alleys, lightly digging this in, and here plant Cauliflowers from the inside-raised plants. Free the beds from weeds and give them a liberal dressing of common salt. Sow two seeds in a 3-inch pot for planting out next year, standing

"The Walled Pool Enclosure," "The West Water Garden," "The Dutch Garden" and "The Pergola" with its fine vista, not only show the continual advance in style, but reveal the wonderful resource and ingenuity displayed by their creator. To quote Mr. Weaver once again, "the Hestercombe gardens are a creation, wherein human imperfection of invention and of workmanship has been brought down to its minimum. They will long stand as a work of art to be admired and an example to be followed. They prove that an architect can be in unison with Nature and that a formal garden can form part of a landscape." Exigencies of space prevent our dealing at greater length with this splendid work, which contains no fewer than 400 pages of folio paper and nearly 600 superb illustrations, plans and diagrams, reproduced in the best *Country Life* manner.

My Garden in Spring.*—It falls to our lot from time to time to review books dealing with horticultural subjects, some good and some otherwise. For Mr. Bowles' book we have nothing but praise. It is entirely different from some which in recent years have been published, and which have been practically glorified catalogues written up to post-cards of some alpine plant "a penny plain and tuppence coloured," inasmuch as Mr. Bowles writes of plants and shrubs in his own garden, and he writes, too, so vividly and bewitchingly as to make one realise what a glorious garden he possesses, or, rather, that his father possesses, through having allowed his son to garden for him. The marvel is how the author, with the multitude of objects which engage his attention, and all good works, too, for the benefit of his fellow-man, finds time wherein to pay attention to horticultural matters and to write about them; but he does so with great success, as a perusal of his book will show readers. Mr. Bowles writes in a crisp, refreshing style, and there is a good deal of humour throughout. He would be a bold man who would dare to criticise Mr. Bowles in horticultural matters; but if the book has a fault, it is that in places it has a tendency to be rather too botanical, and especially in the chapter on Crocuses, which extends to thirty-two pages. Some of the differences in species are so minute as to remind us of water-marks, &c., in postage stamps. It is only fair to bear in mind that Mr. Bowles has been dubbed "Rex Crocorum," and perhaps he felt in writing the chapter that he must live up to the title conferred on him. He writes with such enthusiasm on Crocuses that he hopes to induce others to follow in his footsteps, as he no doubt will, especially as readers are told how to raise hybrids and how to treat them from seed-saving time. Mr. Bowles acknowledges gratefully the gifts of plants he has had made to him, and it is evident that he possesses the true gardening spirit of giving freely to others instead of selling all he can, as is the custom of some "amateur" gardeners. There is every promise of Myddelton House possessing a garden which will (if it does not now) rival Canon Ellacombe's; in fact, it is evident that it is stored with treasures, which thrive under intelligent cultivation. It is gratifying to see that Mr. Bowles is not an advocate for size alone in flowers, as his remarks on page 123 to the effect that he does not want to sit under the trumpet of a Daffodil during a shower and that a small man might feel nervous looking down some of the Daffodil trumpets, which bid fair to become

* "My Garden in Spring," by E. A. Bowles, M.A.; price 5s. net. London: Messrs. T. C. and E. C. Jack.

as large as gramophone mouthpieces, are most amusingly written. Mr. Bowles takes his readers through his garden and describes his treasures so realistically that one almost feels one's self in his company and sees the plants before one. The outcome of this book will be that the author will receive innumerable requests from readers to be allowed to see his garden; and while some enthusiasts will be welcomed by him, he may be plagued, as Dean Hole was, by some people who will persist in talking "about the newest baby or discussing the latest scandal." The chapter on Tulips is especially full of interest, but not a word is said in favour of *Tulipa mauriana*, one of the most brilliant and lasting of Tulips, and purchasable withal for 5s. a hundred. Van Tubergen rightly describes it as "a magnificent Tulip." We are loth to close the book, which every true gardener should read and read again. Like the author's garden, it is a thing of beauty and a joy for ever, and, considering how artistically it is illustrated and how well it is printed, the book should command a large sale.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLET PRINCESS OF WALES (York).—The smallness of the flowers, which is rather common this season in this variety, may be the result of three causes: 1. The plants may not have been vigorous when put in the frame, owing to want of manure in the soil where growing in the open. The smallness of the leaves rather bears this out; or the plants may have had an attack of red spider last summer, which would check their growth. 2. The growth of runners is all against size of bloom. These should be kept off the plants at all stages of their growth, inside and outside. 3. Have the plants suffered for want of water in the frames? If so, that would hinder size being obtained. The great point about growing Violets, double or single, lies in the preparation of the plants before placing them in the frame. Early in April break up into small pieces the old plants that have flowered, rejecting the central or worn-out portions. Transplant these in a fairly rich soil in an open site and a foot apart. Encourage free growth by supplying water as required, constantly stirring the soil about the plants. Remove all runners as fast as they appear, which will add strength to the plants. Lift with a good

ball of soil attached to the roots, and plant them in fairly rich soil in the frame early in September.

ROSE GARDEN.

MANURE FOR ROSES (R.).—Good farmyard manure may be applied to Rose-beds now, or a mixture of 3lb. of superphosphate and 1lb. of nitrate or sulphate of ammonia may be applied per rod at an early date. The specimen sent for determination is the Cornel, or Cornelian Cherry (*Cornus Mas*).

ROSE HELENE (D. C. S.).—This is one of the multiflora Roses, a seedling of *Crimson Rambler*, producing fine trusses of flowers of a delicate rosy pink colour. You should peg down last year's growths, those that are well ripened; then, when they have blossomed, cut them away so as to encourage other growths for pegging down next year. The pest is probably the larvæ of the daddy-long-legs. Give the soil a dressing of Kleenzoll, an excellent soil insecticide, to be obtained of Messrs. W. Voss and Co., Carlton Works, Millwall, London.

PRUNING A PENZANCE BRIAR HEDGE (R. A. S.).—As the hedge was planted in November last, we should advise you, if the plants were fairly bushy, to cut down close to the ground one or two of the growths, and the remainder retain almost full length. This will prevent what you fear—a thinness at the base. Where the growths retained are pliant enough, some could be spread out a little out of the perpendicular, which would have the tendency to produce basal growths without reducing the height of the hedge. In order to do this, a few unobtrusive stakes could be inserted. In subsequent years cut down one or two growths annually. If you desire a tall hedge, a few stout posts should be inserted and some wires attached so that you can secure the growths into something like order and, at the same time, enable you to spread them out for the object previously mentioned. As regards pruning weeping *wichuraiana* Roses the first season, it is best to leave them almost intact, excepting to remove unripe ends. Open out the growths upon a frame of wire or Bamboo. After the first blossoming you should then cut away several of the growths quite close to their base; the result of so doing will be to encourage new growths, which will be for next year's blossoming. Do not defer cutting out the growths later than the end of July.

MISCELLANEOUS.

LEAF-HOPPERS (Sussex).—The little insects on your plants are leaf-hoppers, and often troublesome to a variety of plants. They are very tenacious of life, and difficult to eradicate when once they have obtained a footing. Spraying with a nicotine wash in the evening would, no doubt, kill a large number, but one spraying alone would not be likely to be effective. The best method, however, would be fumigating with one of the excellent fumigants now to be obtained, and a repetition of the fumigation within two or three days, and possibly a third, for even fumigation will fail to kill eggs of such pests.

APPLYING LIME AND CARBONATE OF LIME (G. B. P.).—Ground quick (or unslaked) lime may be used in the autumn, but it would be rather dangerous to use it now, especially so if the Rose trees are already planted; otherwise it is the best form in which to apply lime to a heavy soil. Carbonate of lime may, however, be used without fear, and will have a beneficial effect. Purchase it in the form of ground chalk as finely ground as you can get it, or as broken-up oyster-shells. "Ground garden lime" is a term which conveys no distinct meaning. So long as the stable manure is immediately forked in, it may be added, although lime has been applied. The advice not to add the two together is given because caustic lime, brought in contact with ammonia-containing substances, such as stable manure, leads to the giving off of ammonia into the air. If the manure is buried, any ammonia given off would be absorbed by the earth. If stable manure can be procured, we advise you to use that, for artificial manures never have quite the same beneficial effect upon the physical condition of the soil as does stable manure.

LABOUR FOR FORTY-ACRE ESTATE (E. D.).—The amount of labour required would of necessity vary according to the class of soil, the nature of the land—flat or otherwise—the acreage set apart for flower gardening, and other things. The amount of labour, too, cannot be regulated by the size of an estate; it is what is demanded from it that swallows up labour most of all. A kitchen garden of nine or ten acres of light soil on level ground would require about five men, and of heavy soil about seven. The degree of tidiness required is also a factor to be reckoned with. In all the circumstances, so far as we know them, seeing only "reasonable order" is expected and no glass or bedding-out arrangements are mentioned, twenty-five men might prove sufficient. We give this opinion, however, with some diffidence; and only after a personal knowledge of the estate and what is demanded of it could even an approximately correct answer be given. For the tree stumps you cannot do better than use *wichuraiana* Roses if the stumps are large, or, if not, the smaller-growing *Ivies* and *Clematis Jackmannii* or *C. Viticella* in variety. *Azara microphylla*, *Euonymus radicans variegata* and *Cotoneaster horizontalis* would also prove serviceable.

NAMES OF PLANTS.—*Scottish Gardener.*—The Violet is *Amiral Avellan*, exceptionally well grown.—*Pigeon House.*—*Sisyrinchium grandiflorum* (Spring Bell).—*E. M. D., Kent.*—*Cyclamen persicum flabratum*.—*Mrs. G.*—*Tulipa clusiana* (Lady Tulip).—*R. O. B.*—1, *Coronilla glauca*; 2, *Escallonia macrantha*; 3, *Berberis Darwinii*; 4, *Leucojum pulchellum*; 5, cannot name without flowers; 6, *Berberis stenophylla*.

NAME OF FRUIT.—*G. W. Jenkins.*—*Annie Elizabeth*.

THE GARDEN.

No. 2211.—VOL. LXXVIII.

APRIL 4, 1914.

NOTES OF THE WEEK.

Transplanting Pampas Grass.—Anyone desirous of transplanting or dividing this noble ornamental will find the present time suitable. It will be found advisable to trim off the leaves first, as this makes the dividing of the clump much easier. Some people set fire to the old leaves, and this is, perhaps, the simplest method, but the fire must be kept under so that the plant is not damaged. The burnt appearance will soon be hidden by new growth.

Transplanting or Dividing Hardy Ferns.—Now that the period of rest for hardy Ferns is passing and the roots are getting active for the new growth, it is time to take in hand any transplanting or dividing that may be required. The present state of the roots, in the absence of tender growth, is easily damaged and enables the plants to establish themselves after removal. A good mulch of decayed manure or leaves after planting done will be very beneficial.

Top-Dressing and Planting Asparagus.—Established beds should be gone over and dressed with a mixture of loam and decayed manure, forking a little of the same material into the alleys. Where a new plantation is intended to be made, the present is a good time for this work. In ground where it is a good plan to make a sowing about this time, which in many cases subsequently does better than if one or two year old crowns were planted.

Rose Conference at Biarritz.—The eighteenth annual conference of the French Rose Growers' Society will be held at Biarritz from May 29 to June 1 in conjunction with the Société d'Acclimatation du Golfe de Gascogne. The programme is an interesting one, for, besides the ordinary meetings of the conference, there will be receptions, dinners and other festivities, the chief of which are excursions to King Alfonso's Palace of Miramar at San Sebastian; to Puentarrabia, a quaint old town close by; a mountain excursion to the Grotto of the Pas de Roland; and to Cambo, the birthplace of M. E. Rostand.

An Easily Grown Rock Plant.—*Draba aizoon* is now flowering freely, the small tufts being almost hidden by the golden flowers. It is to be regretted that such an easily grown and readily increased plant is not seen more often in the crevices of rockwork or similar places, for which it and the well-known British species, *D. aizoides*, are especially suited. Both kinds seed freely, and, if the seeds are sown at once, plants are quickly produced large enough to handle for inserting in old walls or niches in the rockery, where they make a bright early display.

Primula denticulata and Its Varieties.—In many gardens these Primulas are flowering to perfection. They are among the earliest of the

one of the curious and not unlovely plants that may be grown in garden or woodland where it is fairly moist and shaded. It usually grows on the roots of Willows and Poplars, but whether it is confined to these we cannot say, and at this season it pushes to the surface of the ground a great number of flowering shoots, sometimes covering from 2 feet to 3 feet square. These are a mass of whitish scales at first, from which erect flowers with a purple corolla, $1\frac{1}{2}$ inches long, are produced. These are not easily compared with other flowers. The upper lip forms a kind of cowl over the stamens, and the lower one a projecting bracket, upon which insects may alight to enter the flower. Large masses that are flowering in the Cambridge Botanic Garden now are of considerable interest to visitors.

The Lesser Periwinkle.—This plant, *Vinca minor*, is of a most accommodating nature, for it will succeed under very varied conditions. In the first place, it is at home clothing a sunny bank, in which position it is just now flowering freely; next, it is well suited for carpeting the ground underneath trees; and, lastly, very few evergreens will hold their own in the smoky districts of London as well as this does. It will succeed there in situations where the larger Periwinkle (*Vinca major*) will die out. When in a

PRIMULA DENTICULATA ALBA, A CHARMING VARIETY THAT FLOWERS IN EARLY SPRING.

hardy Primulas to open, and the heads of lilac and white flowers often show colour as early as February. It is in the early days of April when they are seen at their best, and they are particularly effective when planted in breadths in short grass about the alpine garden. These Primulas like moist positions, but the soil must be well drained, for nothing is more certain to bring about failure than stagnant water about the roots. The best varieties of *P. denticulata* are alba and cashmeriana, the latter having violet flowers with yellow eyes. *P. denticulata* is a native of the Himalayas, rather like *P. capitata* in habit, but the flowers are larger and different in colour.

An Interesting Parasite.—Although *Lithraea clandestina* is a parasite, it claims attention as

healthy state, the foliage of the lesser Periwinkle is of a rich green colour, and the blue flowers nestling among it have a very pretty effect.

Freesia Contrast.—A bunch of this in a vase is very bright and light looking. The three smaller segments of the perianth have a great deal of deep orange marking upon them; in fact, the centre and smallest one of the three is almost all orange. The rest of the flower is ivory white. A potful in a greenhouse makes a good show. Like most of these hybrids, the individual plants branch much more than the old *F. refracta* alba, and Contrast is no exception to the rule. It increases freely, so, although it is expensive to buy in any quantity at present, a small stock will soon provide plenty for cutting and for pots.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Viola Jackanapes.—In your issue dated March 28 a correspondent, Mr. T. Smith, says he is unable to obtain *Viola Jackanapes*. This variety is offered by Messrs. Forbes of Hawick in their 1913 catalogue at 2s. 6d. per dozen or 15s. per hundred, so I expect they still catalogue it, and if your correspondent is anxious to get it, he should apply to this firm.—C. M. BAILEY.

Plums from the Cape.—The article in your issue of March 14, page 135, on Japanese or Cape Plums was most interesting, and while in one part of the article Mr. Bunyard rather suggests that to grow these Plums (as from experiments already made in this country out of doors) would be a failure, yet at the end of his article he as much as says that they would be a success on walls. I am writing, therefore, to enquire whether any readers of *THE GARDEN* have ever succeeded with these Plums on walls out of doors, and whether the crops have been worth the space on the walls?—W. F. M. COPELAND.

Erica carnea on Limestone Soil.—In your issue of March 14 you ask for further information as to the behaviour of *Erica carnea* in limestone soil. Some years ago I planted it and its white variety on a small limestone rockery, the soil of which consists almost entirely of old mortar rubbish. I found that it thrived far too well for the space accorded it, and I was obliged to remove it to make room for plants of less vigorous growth. It is a pity that any of your readers should avoid growing this beautiful little shrub (in my opinion the best of the *Ericas*) owing to the mistaken notion that it shares with others of its tribe a dislike to lime in the soil.—NORMAN RUSHWORTH, *Beechfield, Walton-on-Thames*.

Lime for Lawns.—A correspondent asks in your issue of March 21 what effect lime has upon lawns and the amount to be applied. I would say that nearly all old lawns would be benefited by a dressing of lime, especially if the turf were mossy. Old lawns are often inclined to be sour, and, of course, it is well known that lime corrects the acidity of the soil. Again, where manures are used containing a large proportion of nitrogen, the soil will become surcharged with it and the turf will suffer. A dressing of lime will set free the ammonia, and thus turn what was harmful into useful plant food. Lime, however, should not be used too often, or it will impoverish the soil. I should say that in cases where the turf was regularly fed with artificial manure, once in three or four years would be sufficient. In cases where no manure was given, a dressing once in six years would be often enough. Slaked lime, finely ground, should be used, and it should be evenly spread on a still day at the rate of 3oz. per square yard. Autumn is the best time to apply it, so that the winter rains may put it all out of the way before mowing commences in the spring.—J. DUNCAN PEARSON, *Lowdham, Notts*.

Road Sand: A Caution.—At one time the sweepings of the roads were looked upon as of great service to the plant cultivator, being not only spread upon the land, but also freely mixed with potting soils. Now, with the increased use of chemicals on the roads and the fact that motors have to a great extent taken the place of horses, it is frequently dangerous to use road sweepings in growing plants of any kind.—H. P.

The Leopard Moth.—Six weeks ago I was pruning an orchard of trees which are six years old. As I was taking off some suckers from the scion where it was grafted, I discovered a hole eaten in the scion. Naturally, I examined it carefully, as the tree appeared to be in good health. I cut the tree down and found the hole was eaten up the main stem. I discovered a very large grub, which is, at the present time, embedded in the Apple stem I have enclosed. You will see how it is discharging the wood it is living on.—WILLIAM GAIGER, *The College*

SECTION OF APPLE SHOOT BORED BY LARVÆ OF THE LEOPARD MOTH. THE GRUB AND SHOOT HAVE BEEN SLIGHTLY ENLARGED.

Gardens, Studley Castle, Warwickshire. [The grub sent by Mr. Gaiger, and illustrated herewith, is that of the leopard moth, *Zeuzera Aesculi*. This is a rather large moth, with wings of white ground colour, freely spotted with roundish blue-black dots. These moths are not very common, though widely distributed over this country. The grubs may be killed by thrusting a stout wire up the gallery that has been formed. Branches that have been attacked often live for years and bear good crops of fruit.—ED.]

Tall Antirrhinums.—It is obvious that "G. L. J.," whose note appears on page 142, issue March 21, has never seen really tall Snapdragons, else the comparison to monstrosities would not have been made. In my opinion they are the grandest of all Snapdragons, and almost rival the Hollyhock in stately beauty. The only varieties for which I entertain a feeling bordering on contempt are those of the dwarf section, yet many people grow these to the exclu-

sion of all others. I keep in mind the French saying that each one has a right to satisfy his own tastes, and allow for personal proclivities, even for those of "G. L. J.," and trust in the future he or she may be able to increase by twofold at least the period of the season of bloom, which is coincident to the strength of the plant, including increase of stature. In reply to "F. R. H. S.," I grew Cottage Maid some years ago, and found the name represented eleven colour variations. It has probably improved since.—R. P. BROTHERSTON.

Myosotidium nobile.—It may interest your correspondent Mr. Brotherston, whose note appears on page 142, March 21 issue, to know that the New Zealand Forget-me-not is quite a success in the open in South-West Scotland. The plants flowered and set seed freely last season; but, not having tested the seed, I cannot answer regarding the fertility of it. It is said that in its native isle this plant is to be found growing on damp sand by the seaside; therefore it is advisable, when preparing a site for it, to take out a hole about two feet square and fill it with sea sand. Like many other thick, fleshy-rooted plants, this is most impatient of root disturbance. A fine illustration of this appears here in a plant that was transplanted two years ago and given no sea sand; it seems to have made no growth since then. Some writers describe this as a beautiful blue, but the flowers here do not warrant that description, being very pale. The reason may be that this is a variable plant, in that there may be various shades of blue. Apart from its flowers, it is a highly ornamental plant for the garden during the spring and

summer, with its large, heart-shaped leaves and curious seed-heads. The plants here are growing in a cool, damp position on the north side of a dense Beech hedge, which seems to suit them admirably. At the time of writing (March 21) there are many flower-heads appearing, which were exposed to the following frost without in any way damaging either flower-buds or foliage: March 9, 15°; March 10, 8° (thermometer on the grass). I

have no doubt it would prove sufficiently hardy in many colder districts than this is if it was given the protection of a little dry hay or Bracken and a bell-glass over the crowns during severe weather.—R. FINDLAY, *The Gardens, Logan, Stranraer*.

—When in Cornwall last week I called at the beautifully situated gardens of Enys, and, seeing *Myosotidium nobile* in such grand condition, I asked Mr. Frost, the gardener, to give me particulars of treatment. He stated: "As you see, the New Zealand Forget-me-not grows very freely here under a north wall, in peat and sand, with a dressing of seaweed in early winter. It flowers grandly, and produces seed in more or less quantity, according to the summer, from self-fertilised flowers. The seeds ripen in August, and germinate quickly in cold frames if sown as soon as gathered. The young plants have been uninjured by 10° of frost, and the plants are evergreen."—NORTH SOMERSET.

Triteleia uniflora as a Pot Plant.—After the very interesting little note and illustration of *Triteleia uniflora* in your issue of March 14, I am wondering if many of your readers try it as a pot plant for flowering early in the year, with a little heat. I have grown it as such for about twelve years, and find it very useful for furnishing the front of the stages, also for standing around Palms and vases in the house, as the leaves droop over the sides and look very pretty. I generally use 4-inch pots, with about seven or eight bulbs in each; just pot them in the autumn and stand them in a cold frame till the growths are about an inch and a half long, and then take them straight into the house with a temperature of about 60°. They do not seem to mind a little forcing. I have found they can be ripened off in their pots and potted up again in the autumn.—E. BARBER, *The Gardens, Renton Hall, Surbiton.*

Lachenalias as Room Plants.—I have read with much interest the note in THE GARDEN, page 142, March 21 issue, by the Rev. J. Jacob on the culture of *Lachenalia Nelsonii* as a room plant. I agree with him. Few take the trouble to grow them well, but I am sure any gardener who has not given them a trial would find them most useful plants during February and March for room and table decoration. I have grown these pretty Cape Cowslips, as they are called, for forty years. At the present time I have about two dozen pots of *L. Nelsonii* in flower. They are equally good in baskets, planted in moss and soil, and look very dainty when suspended from the roof of a greenhouse, but they must be well supplied with water. I think the reason why so many do not succeed in growing them well is that they do not pay enough attention to ripening off the bulbs, which I consider is so necessary for successful culture.—W. DRIVER, *Stonehouse, Gloucestershire.*

Cold Storage for Cut Roses.—A correspondent asks for information about cold storage for exhibition Roses. This is adopted, I believe, by some of the American florists, and undoubtedly there is much to be said in its favour from a florist's point of view. I should imagine, however, that it would scarcely work beneficially for the exhibitor, because as a rule he has to contend with theretchedly ventilated canvas tents that are so owing to the Rose. I think its success would much depend upon the time of year and the atmosphere the flowers were placed in after leaving the cold storage. I remember, many years ago, that some cut specimens of new Roses were sent over from the United States in cold storage, and they were exhibited in London as fresh-looking as though just cut. But this was in the winter-time. I can see the advantage to a Rose exhibitor of using cold storage if the blooms would not show wither after being taken out, which I much prefer, as some Roses might be taken from one show to another. Besides, we could retard a bloom to a certain show day. If this is ever adopted it will make a considerable difference to our exhibitions. Perhaps some of our amateur enthusiasts will experiment and give in these columns their results.—DANECROFT.

Perpetual-flowering Carnations for Bedding.—The very beautiful beds of these charming flowers which are sometimes seen leads one to hope that here long they will figure very largely in important schemes of bedding. At present there are only two or three varieties which are used to a great extent for bedding purposes; but there is no doubt that these will be considerably

augmented. Last year I used Mrs. Burnett and Britannia. The former was planted in a bed by itself, over a groundwork of Sweet Alyssum. Part of the plants used had already done good service by flowering all through the winter months. The plants were partly cut down in March and placed in a light structure till the beginning of May, when they were subjected to a course of hardening off, together with some smaller plants which were struck the previous autumn for the purpose of bedding. Towards the end of June they commenced flowering, and continued to flower profusely till frost appeared late in the autumn. The variety Britannia was planted in a mixed bed of border kinds, and if any evidence was needed to convince one that the perpetual kinds will one day reign supreme outdoors, it was to be found here. Apart from the perpetual nature of its flowering, the colour and form of the flowers of Britannia were equal to any of the border kinds. I have not tried any other varieties outdoors, but I presume that the drawback with most is that their flowers will not stand the vagaries of our climate. But no doubt the Carnation hybridists will before long present us with varieties which will overcome this difficulty.—E. HARRISS, *Lockinge.*

Aster Disease.—I can fully substantiate the remarks of "F. M. S." on the advisability of treating Asters as hardy annuals. For many years I have made it a practice to sow Asters in the open ground at the latter end of April or the first week in May, although, owing to insufficiency of space, I have not been able to allow all to stand where sown. There is no questioning the fact that Asters never do so well as when grown without a check; and in transplanting at a late stage the plants certainly get a severe check, especially if dry weather follows planting. The practice of sowing in the open is the recognised system in the United States of America; and nowhere in the world are Asters grown on so gigantic a scale and in such phenomenally good form as in America. Fully ten years ago I was in the habit of sowing my seed in the open, and it is astonishing to me why so many are addicted to sow Asters under glass in heat. During my connection with a Midland firm we always made trial sowings of annuals in the open, and I have never seen better Ten-week Stocks than these late April sowings produced. I do not agree with "F. M. S.'s" policy of non-thinning. If he handled such varieties of Asters as Peerless Pink, Violet King and the various late branching forms, and desired to see them run to their 2½ feet to 3 feet limit, with flowers up to 7 inches, he would find it necessary to give a full foot of space. Regarding the immunity from disease of open-air sown plants, this is largely, if not entirely, due to the fact that the seedlings do not get leggy in their early stage. "F. M. S.," by avoiding transplanting, entirely guards against the possibility of the plants being set too deeply. On no account must any foliage be allowed to touch the soil. The lower leaves, if not clear of the ground, should be removed, otherwise these commence to decay and stem-rot follows. Plenty of lime in the ground is essential.—T. W., *Kent.*

FORTHCOMING EVENTS.

April 6.—United Horticultural Benefit and Provident Society's Committee Meeting.

April 7.—Royal Horticultural Society's Exhibition. Lecture at 3 p.m. on "The Cultivation of Amaryllis." Scottish Horticultural Association's Meeting.

SEASONABLE NOTES ON AURICULAS.

THE month of April will prove whether the grower has been successful or otherwise. A few of the alpine varieties will begin to open their flowers, and by the end of the month a fine display will be the rule in the majority of collections. Few plants can equal Auriculas for richness of colour, and they are still among the choicest of flowers that bloom at this season.

Watering.—The plants should be looked over daily for watering purposes, as they are now most active, and the weather will also cause them to dry more quickly than hitherto. Dryness at the root must be avoided, or the flowers will be ruined. A little more attention will be necessary in regard to shading, and the blooms must be protected by a thin blind from all strong sunlight, although, when the flowers commence to expand, the early morning sun will be of considerable benefit. Ample ventilation should be given and the frames kept quite cool to prolong the life of the spikes.

Preparing Plants for Exhibition.—The following remarks are not intended for the exclusive use of exhibitors, and the reader will notice that some of the instructions given are just as necessary for the amateur who keeps his plants at home as for the man who exhibits. In most instances a neat little green stick should be placed to each stem, and this is best done in the early stages of growth, before the stalk is bent over by the weight of the flowers, and the pips, as they are called by the florists, will in some cases require adjusting, so as to show off the truss to the greatest advantage.

Where the trusses are very dense, it will be necessary to thin the buds, removing two or three at a time with a pair of tweezers or small scissors. With the alpine a lot of thinning is not carried out, but the show varieties are subjected to more severe treatment, especially the greens, greys and whites. If the exhibitor can secure four or five good flowers upon a stem, he is usually satisfied. They must not be crowded, and each flower should be as perfect as possible.

The selfs are also thinned, but a few more flowers can be allowed to develop if the plant is strong. The grower must use discretion in these matters, and if he allows sufficient space to prevent undue overcrowding, a fine truss of blooms will be the result. See that the pots are clean, a clearly written label in each pot (or the reporter may overlook your exhibit), and a layer of fresh moss around each plant. Be very careful in handling the plants, so as not to bruise the flowers or disturb the farina on the leaves and stems.

Saving Seed.—Where the beginner desires to save some seed with the object of securing a few good varieties, it will be necessary for him to work on some such lines as given below. With the show varieties a green edge should be cross-fertilised with another green-edged kind, a grey edge should be mated with another grey edge, and a white edge with a white edge. In the selfs the colours should be kept together as far as possible, and with alpine a gold-centred variety can be pollinated with another gold-centred kind, and so on. Having selected a flower to be fertilised, the anthers must be removed in the early stages before the pollen is ripe, and if the plant is held in a downward position, they will readily fall to the ground.

T. W. BRISCOE

DAFFODIL NOTES.

The Season.—Winter has paid his annual visit to the British Isles this year in March instead of January. As George Stephenson said of the hypothetical cow in front of a railway train, it is "bad" for Daffodils when this icy, boisterous visitor catches them, as it were, off their guard. They do not like it. They feel that the Clerk of the Weather, who is supposed to arrange all these visits, has "taken them in." They cannot do much to show their resentment, so they just sulk and we get small flowers and short stems. I ruminate thus to let our friends elsewhere know what sort of a beginning we have had with our outdoor season. And yet the next Royal Horticultural Society's Tuesday meeting comes along, and there, at any rate, there are few signs of the unwelcome visitor.

Flowers at the Royal Horticultural Society's Show on March 24.—"Wilson is exhibiting" has to Daffodil persons much the same effect as "Gladstone is up" used to have on members of the House of Commons. They are seldom, if ever, disappointed, for a Wilson exhibit is always full of good new things. It was no exception on March 24. Perhaps the distinguishing feature was the fine new series of the Schoot type of Poetaz that have been raised by Mr. P. D. Williams of St. Keverne, Cornwall. He is our principal English raiser of this bunch-flowered class. His Rubellite and Lucasta are both of them remarkable developments, in that they give us such red eyes with such fine white perianths. Rubellite I described last year, and it is also in the novelty list of the 1913 Year Book. The solid red eye, relieved in the very centre by the green top of the perianth tube, resting on a pure white perianth about two and a-half inches in diameter, is very delightful. This pleasing impression is further enhanced by the three or four large blooms being so arranged on the stem that they do not jostle and put one another too much out of shape. Lucasta is similar, but the eye is a trifle smaller and more suffused than solid; that is to say, its centre is of a much more orange shade than the circumference. At a little distance away I almost thought it looked "rimmed." Personally, I think I admired it more than Rubellite. It depends how far one leans to the all red. Ossian was the only other one that was named. It features the Polyanthus Narcissus more than the others, and in my opinion was not to be compared to the other two, although its orange-toned large eye was effective. There were several others under number. Some I did not like and some I did. In the latter category was a distinctly good all yellow, which I think will develop into

something useful, but I cannot remember if it had a long enough stalk. The other outstanding feature of the group was an early edition of the now well-known Buttercup, but two weeks earlier to bloom and of a much deeper shade of yellow, following in this its mother King Alfred, as Buttercup does Emperor. The committee gave it a garden and a cutting award. As a show flower it does not come up to the older variety. Its measurements are $3\frac{1}{4}$ inches diameter of the perianth, $1\frac{1}{4}$ inches length of cup, and 1 inch width at top. The "loving" eye, the eye of the man who observes and asks and thinks, must

yellow perianth. Size, 4 inches by five-eighths of an inch by three-quarters of an inch. Both Beryl and Bernardino were shown in superlative condition. An exhibit of a totally different style was that put up by Messrs. Bath of Wisbech. Roughly speaking, two-thirds consisted of well-grown Tulips in bowls, and one-third of a select, fresh-looking little lot of rather choice Daffodils. Flame occupied the central position, and on account of the way in which my good friend Mr. Bennett-Poë cracked it up a fortnight before, I had a specially good look at it. To all intents and purposes it is an enlarged and

intensified Barrii conspicuus. Mr. Leak told me it was not doing it justice to form an opinion from the blooms that I saw. It would be on view again before the end of the season. Hence I wait, as my readers must also, before I make a final pronouncement. Eastern Maid was the one absolutely new variety to be seen there. I know nothing of its parentage, but its general shape betokens a touch of cyclamineus in its composition. It has the thrown-back petals which are so suggestive. These are wide and pointed, and of a delicate greenish primrose shade, which is very taking. The cup is narrowish and long, pale yellow in colour. It was presented to the committee, who in return presented it with an award of merit as a show bloom. I like it very much. It would ornament any "fifty." I am told there is a small stock of it, so perchance it may be "buyable" before long. Of the exhibits of Messrs. Barr, Mr. Bourne, and Messrs. Cartwright and Goodwin I will write next week.

Registration of Names.—The new Classification List is now out, and can be obtained for a shilling from the Royal Horticultural Society, Vincent Square, Westminster. Mr. C. H. Curtis, the secretary of the Daffodil committee, is going to put up a list of all the fresh names sent in for registration at the fortnightly meetings of the committee. The first one was put up on March 24, and contained sixteen. This is an excellent idea, for which we owe our secretary many thanks.

It is provoking to fix on a name and find it taken. But as the number of seedlings becomes greater and greater, we all find it more difficult to avoid pitfalls; hence the utility of this publicity.

JOSEPH JACOB.

[In our next issue the Rev. Joseph Jacob will continue his observations on the Daffodils shown at the Royal Horticultural Society's show on March 24, while brief descriptive notes on the four Narcissi to gain awards appear on page 172. The illustration of Narcissus Rubellite is reproduced by the courtesy of Mr. P. D. Williams of St. Keverne, Cornwall.—ED.]

NARCISSUS RUBELLITE OF THE POETAZ SECTION. THE FLOWERS ARE PURE WHITE WITH A DEEP RED EYE.

have observed with a considerable amount of surprise No. 153, quite a nice bicolor, with a green water-mark down the middle of each petal, like the yellow down the centre of the segments of many Tulips. Not a Conqueror certainly, but withal something to have in one's garden among the early yellows and the early red cups. These are becoming fairly common, but bicolors are still rare. Tita, which was another fine thing in this collection, is one of the above-named early red cups, and of so much value for the garden and cutting that the committee gave it an award. It has a suffused cup and a good

SEASONABLE NOTES ON PEACHES & NECTARINES.

Trees Under Glass.—Although the trees are hardy when allowed to grow naturally on open walls in this country, the forced growth of the trees under glass must not be checked by careless ventilation during frosty nights and while east winds prevail. If the ventilation of the structure is perfect, it is wonderful how well these fruit trees thrive in an unheated house. In heated houses the growth of the trees is now quite forward. On every day that promises to be bright and sunny, the fires must be stopped about nine o'clock in the morning. A little top ventilation will be beneficial, but no front ventilation should be given at present. The borders and paths ought to be damped in the early part of the day and again after noon, the ventilators being closed between three and four o'clock. The young fruits will be quite prominent and the first thinning must be done. This will consist of the removal of ill-placed and small fruits; the largest ones on the fore part of each branch must be left now, to be reduced in number at a later date. The young shoots are several inches long, and the final thinning of them must not be delayed any longer. On a shoot from 18 inches to 2 feet in length, three young ones should be left, namely, one at the point, one near the centre, and one quite at the base. On shorter branches leave two young shoots, namely, one at the point and one at the base. Syringe daily; twice on fine days—once early in the day and again when the house is closed. The thorough wetting of the leaves keeps them free from red-spider and thrip, and, furthermore, promotes a healthy growth. As a further preventive of red spider, scatter a little soot on the border at syringing time in the afternoon. This should be done about once a week. The ammonia arising from the soot is beneficial to the Peaches, and prevents the spread of red spider.

Trees in the Unheated House.—These will require the same treatment as those in heated structures, except in the matter of damping and syringing. Less water must be sprayed on the path and border, and only on very fine days must there be an afternoon syringing as yet. The gradual disbudding of shoots and fruits must be done while both are small.

Trees Trained on Open Walls.—The blossom must be protected from frosts. Pull down the scrim, tiffany or nets in the daytime if heavy rains prevail and there seems to be danger from frost at night. Frost does more damage when the flowers are wet than when they are quite dry. It is beneficial to continue the protection of the tiny fruits for about ten days. **GEORGE GARNER.**

HARDY SHRUBS FOR THE GREENHOUSE.

IN the depth of winter a few of our hardy shrubs, such as the *Laurustinus*, *Jasminum nudiflorum*, *Erica carnea*, &c., with such berry-bearers as *Skimmias*, *Aucubas* and *Pernettyas*, contribute their share to the embellishment of the greenhouse. It is, however, in the early months of the year that this structure depends largely for its show of blossoms upon hardy shrubs that have been forced prematurely into bloom. This practice of forcing shrubs is now greatly on the increase, and immense numbers are grown specially for the purpose.

A BUSH OF WHITE LILAC MARIE LEGRAYE. THIS IS A SPLENDID VARIETY FOR FORCING.

Of the different subjects, perhaps the most popular of all are the Azaleas, of which there is now a great variety available. The compact-growing *Azalea mollis*, which flowers in great profusion, has for the most part blossoms of some shade of terra-cotta; but there are some improved forms, notably the rich yellow *Anthony Koster*. The Ghent Azaleas are also amenable to forcing, though they are not so generally employed as *A. mollis*. In the Ghent kinds the flowers are, as a rule, smaller, but the range in colour is more extensive than in *A. mollis*, while they have also a more pronounced perfume.

Next to these may be mentioned their near allies, the *Rhododendrons*, which are very showy under glass. Many of them, however, do not force readily, as, if kept too warm, the flowers will

grow blind. Good kinds for the purpose are *R. arboreum wellsianum*, *R. Blanche Superbe*, *R. caucasicum album* (Cunningham's White), *R. c. pictum*, *R. mirabile*, the different forms of *R. nobleanum* and *R. Prince Camille de Rohan*. Besides these, the small-growing kinds, such as *R. præcox*, *R. Rosy Bell* and *R. Early Gem*, are very readily forced.

Many rosaceous plants contribute largely to the floral display in our shrubberies in early spring, and a great many of them will do well under glass. Among them may be mentioned the double-flowered Peaches and Cherries, with several of the smaller-growing forms of *Pyrus*. Of all plants belonging to the order, there are no greater favourites for forcing than the double forms of

Prunus japonica and *P. triloba*, both of which are grown for the purpose in very large numbers. *Kerria japonica flore plena*, with its rich golden blossoms, like little Roses, must not be passed over in any selection, while some of the *Spiræas* claim to be included, the best being *S. arguta*, *S. confusa* and *S. prunifolia flore plena*, this last being remarkable for its tiny double, rosette-like blossoms. Magnolias, too, are very striking, not only such as *M. Lennéi*, with its large, chalice-like blossoms, but some of the smaller kinds, notably the charming little *M. stellata*, so recently illustrated in *THE GARDEN*.

Lilacs are, and have been for many years, forced in large quantities. Immense numbers of sturdy little bushes bristling with flower-buds are sent to this country from the Continent every year. The single white *Marie Legraye* is the most popular of all. Another that is largely grown is *Charles X*. Of double-flowered kinds, *Mme. Lemoine*, white, is grown more than any other.

Deutzia gracilis has for the last fifty years or more occupied a foremost place among shrubs for forcing, and at the present time its position is as secure as ever. Of the newer kinds, the larger-growing *D. Lemoinei* forms a very suitable companion to it.

A subject that has come largely to the front within

recent years for flowering under glass is *Wistaria sinensis*, as when this is grown in standard form the long, pendulous racemes of mauve-coloured blossoms form a very striking and distinct feature among its associates.

Apart from the different subjects enumerated above, there are many others, all of which are available for the same purpose. Among them may be mentioned the Brooms, *Forsythia suspensa*, *Weigelas*, *Staphylea colchica*, the Guelder Rose and its Japanese form, with the orange-coloured *Berberis Darwinii*. A valuable shrub for greenhouse decoration, though it cannot be had in bloom early, is *Hydrangea paniculata grandiflora*, whose massive, pyramidal-shaped heads of cream-coloured flowers are very ornamental. **H. P.**

ANNUALS IN THE ROCK GARDEN.

AS a general rule, the rock garden is pre-supposed to be a type of herbaceous border where only perennial plants may be grown, but amateur readers must realise that there are many annual flowering plants quite amenable to successful culture among the rocks and stones; indeed, the introduction of a nice blending of colours by this means adds increased charm to the place, and without much trouble leads to a greatly enhanced appearance at certain times of the year. Where bulbous plants that bloom in spring are features of the place, annuals may be made to produce a succession of blossom. They can be sown in the soil round the bulbs, or grown elsewhere and transplanted into position. Most suitable of all are the dwarfs, semi-dwarfs and trailing plants which are frequently grown in the garden, and, in general, those that do not dislike a dry soil are most satisfactory. Half-hardy subjects (marked with an asterisk in the list) have to be raised in a cold frame, but the others can quite well be sown where they are to grow. Personally, I prefer to grow them in the borders and transplant them in due season; in sooth, I thin out my annuals with this idea in view. Sow the seeds rather thickly if the plants are to be grown continuously in the rock garden, in case bad rains in April may wash away some of the surface soil. Thin out the seedlings when they have made four true leaves.

Here are some of the very finest varieties, selected mainly for brightness combined with massive effect: **Abronia umbellata*, fragrant, lilac, trailer; **Ageratum Dwarf Blue*, very free-flowering; *Alyssum maritimum*, dwarf, white; *A. saxatile* (Gold Dust), yellow, both very fine; **Arctotis breviscarpa*, orange colour, suggestive of the *Calendula*; *Campanula attica*, either in purple or in white varieties, profusely flowering dwarfs; dwarf hybrid *Candytufts*, various varieties; *Collomia coccinea*, suggestive of the *Bouvardia*, scarlet and tall; *Eschscholtzia Mandarin compacta*, a brilliant orange; *Gilia nivalis*, white, and *G. minima cærulea*, beautiful blue, both 4 inches to 6 inches in height; *Godetia Bijou*, the smallest of its class; *Gypsophila repens*, red and white; *Ionopsidium acaule*, a close-growing, very dwarf plant, lilac; *Leptosiphon androsaceus*, pale purple; *Limnanthes Douglasii*; *Kaulfussia amelloides*, white, blue or crimson; **Mesembryanthemum tricolor*, must be grown in a sheltered, sunny nook; *dwarf *Nemesias*, various, but only employ the most brilliant kinds; *Nemophila*; **Nycterinia capensis*, white and blue dwarfs; **Pansies* and **Violas*; **Phlox Drummondii* of the smaller sorts; *Platystemon californica*, a kind of trailing Poppy with

cream flowers; **Portulaca*, very dainty; **Salvia roemeriana*, fine scarlet flowers; *Sanvitalia procumbens* of double sorts, yellow and crimson; *Saponaria calabrica*, rose or white; **Schizanthus pinnatus*, very floriferous; *Silene pendula compacta*, various colours; **Tagetes signata pumila*, yellow gems; *Virginian Stock*, fine in the mass, but be sure to get selected forms; *Veronica glauca*; and *Whitlavia grandiflora*, rather large.

H. H. A.

SAXIFRAGA HAAGEI.

WHEN better known, this garden hybrid promises to be quite a favourite among early flowering

SAXIFRAGA HAAGEI. AN EARLY FLOWERING HYBRID FOR THE ROCK GARDEN, WITH DEEP YELLOW FLOWERS.

Saxifrages. The flowers are bright yellow, rising about two inches above the soft green foliage. The flower-stems are red, and, when well grown, there are usually seven flowers to each inflorescence. This hybrid was raised by crossing *S. sancta* and *S. Ferdinandi-Coburgii*, and is a worthy descendant of two admirable parents. In general appearance it somewhat resembles *S. sancta*, the well-known species from Mount Athos. It does best in a sunny position and limestone soil. The flowering season is March and April, and it makes a suitable companion plant in the rock garden to the lighter-coloured *S. apiculata*.

HALF-HARDY ANNUALS.

THERE are some very beautiful annuals which really only come to perfection when raised in gentle heat with a protective covering of glass, such as a greenhouse or frame affords, or simply in boxes covered with glass; hence the name "half-hardy." Where space is limited or from other causes a greenhouse or frame is not available, the last-mentioned method will be found to answer admirably for many varieties if placed in a warm and sheltered aspect. A light frame is, however, a most useful adjunct

to any garden in this connection, and will repay its cost even during its first season. After raising young plants the frame top can be removed, some additional soil dug in, and the space used as open garden for the reception of some of our seedlings, thus economising room. The writer has frequently grown prize annuals in this way. It will be found good practice to sow seeds in shallow pots, pans or boxes which can be fairly easily handled. It is important that these receptacles should be thoroughly well drained. Above coarse siftings of loamy turf, a mixture of fine soil and leaf-mould, with a good sprinkling of sharp sand, comprise a fertile seeding compost. A test for a good soil is that it does not clog when pressed together in the hand.

The whole of the varieties given in this article may be used, after hardening off, in a similar capacity to annuals of the hardy type, *i.e.*, massed in small beds, each of a separate colour (a charming method where sufficient room is available), or in a mixed border among more permanent plants.

Bearing in mind a few general principles, there should be every reason to expect success, the result being a garden of beauty and perfume. The interesting practical experience also gained by growing one's own plants will be found to be of great value, and withal fascinating. Not only that, but it adds credit to the garden, and, incidentally, to the gardener. It is best to sow very thinly in receptacles which have previously been lightly watered, covering the seeds with about their own thickness of soil passed

through a small-meshed sieve. The seed-boxes should afterwards be kept slightly on the dry side, and, if those containing very small seeds absolutely require moisture, they should be stood for a time in vessels of water. An important factor is to prick out early, when two pairs of leaves have formed, to 3 inches or 4 inches apart, setting the plants in moist soil up to their seed leaves. If given plenty of air, kept near the glass and away from hot sun, sturdy plants should be the result.

The following selections will be found to contain some of the best: Stocks.—Varieties of

Ten-week, East Lothian and Brompton; sow early. *Salpiglossis*, 2 feet (various). *Phlox Drummondii*, 1 foot (various). Double Asters *Victoria*, *Comet* and *Ostrich Plume*. Single Asters *sinensis* and *Single Comet*; use wood-ashes and a little old soot as manure for Asters. *Schizanthus hybridus grandiflorus*, 1 foot (various). *Verbena*, 1 foot (various). *Nemesia strumosa Suttonii grandiflora*, 1 foot (various). Double *Zinnia*, 1½ feet (various). *Marigold*, 2 feet, *African*, *Lemon*; *French*, *Tall Orange*. *Cosmos*, 2 feet to 3 feet, *Rose Queen*; *Cosmos* requires very little manure. *Dimorphanthera aurantiaca*, 1 foot, orange, black centre. *Gaillardia picta*, 1 foot, yellow and scarlet. For climbing: *Cobæa scandens*, purple, *Tropæolum canariense*, *Humulus japonicus variegatus* (annual Hop), and *Ipomœa coccinea*, scarlet; sow where plants are to bloom. For edging: *Lobelia*, blue and white, and *Verbena nana compacta*. Everlastings (for winter decoration): *Helichrysum*, 1 foot to 2 feet (various); cut the blooms before fully open. *Rhodanthe*, 1 foot (various). B. W. LEWIS.

PLANTING ALMONDS FOR EFFECT.

How often one sees the Almond and other spring-flowering trees with red or pink flowers planted in close proximity to a red brick building, so that the beauty of the flowers is lost against the unsuitable background! With summer-flowering trees this may not be so apparent, but with trees that bloom before the leaves unfold, too much care cannot be given to the choice of a favourable site.

Possibly the Almond is seen to greater disadvantage than any other tree, for, owing to its adaptability to town life, it is frequently seen in small gardens near large towns, and especially in the suburbs of London. Indeed, it has been observed that the Almond produces a greater abundance of blossom near to main thoroughfares than it does in the quiet surroundings of a large park or garden. The reason given is that the trees near thoroughfares are unmolested by birds, whereas in sequestered places the birds do considerable damage to the buds in the spring.

In the accompanying illustration is shown the Almond flowering with good effect near a garden walk. Here the trees have been thoughtfully interspersed with dark evergreen conifers, against which the light-coloured flowers of the Almond trees are thrown up in marked contrast. The flowering of the Almond is always a matter of interest to Londoners. This year the first blooms were noticed in the early days of February, last year on January 25, but in the cold spring of 1909 the first blooms were not observed till April 1. The Almond is known botanically as *Prunus Amygdalus* or *Amygdalus communis*, and the fruits are clothed with a velvety pubescence. On the Continent the Almond is grown for its fruits, but in this country they do not appear to have any commercial value.

THE IMPROVEMENT OF GARDEN ROSES.

THE article upon "The Improvement of Garden Roses," in your special Rose Number of October 11 last, from the pen of "White Rose," was very interesting, owing to the superfluity of new varieties. Last year established a record so far as the National Rose Society and gold medal awards were concerned, and the behaviour of the varieties that have been so honoured will be watched with keen interest by growers all over the country. The demand for Roses is now immense, and during the last decade has altogether altered in character. Exhibition varieties purely and simply, and also those sorts that are not of value as "cut-backs," have fallen upon evil days, and the

has also the effect of debarring many excellent garden Roses from the highest award a variety can obtain. After all, however, as your correspondent puts it, there is another court of appeal, and that is the amateur growers of the country.

I know that "White Rose" is very interested in the welfare of the National Rose Society, and that he is a very active and sympathetic member of that organisation, and I take it as a very hopeful sign when I see him writing that, "As matters are now arranged it is to the amateurs chiefly and finally that we must look to secure the results we desire." The amateur rosarian of to-day is rapidly becoming quite independent of catalogue descriptions of Roses, and, what is more, he is becoming very chary of the awards to new varieties. The modern amateur—I am writing of the majority—is a grower of sturdy and healthy independence; he knows what he wants for decorative purposes, and he sees that he will get it ultimately.

ALMONDS EFFECTIVELY GROUPED WITH DARK-LEAVED SHRUBS.

demand for Roses of this description is rapidly becoming less and less. The call is now for what are termed garden or decorative Roses, and raisers, judging from the "National" shows of last year, have not failed to respond.

But there is one unsatisfactory point in the judgment of this somewhat modern section of Roses. The system of granting awards to exhibition Roses may be sound enough, for, after all, the flowers are only required to be at their best upon the show benches; but, surely, a totally different method is necessary for assessing the value of varieties that are required for the decoration of the garden and home. The value of such a Rose can never be ascertained from a mere collection of flowers staged upon a bench in tubes or boxes. The present system, while admitting many valuable Roses to premier honours, and at the same time doing a similar service to some that are worthless,

"White Rose" observes that the amateur will get what he wants by vigorous criticism and the elimination of undesirables, and this is precisely what is being done. For example, in the West of Scotland there is a very large and increasing circle of enthusiastic amateur rosarians. These growers have their wants catered for by weekly articles in the columns of an influential Glasgow evening newspaper. The editor of the gardening columns last autumn took a plebiscite of his readers upon the twenty-four best garden Roses, and the result was a list that reflected little credit upon the enormous number of new Roses of recent years. Nearly one hundred and fifty lists were received by the editor, and it is obvious, from the observations made by the contributors, that they were really up-to-date and had tried most new sorts. If criticism of this description becomes more general—and it fully seems to tend in this direction—it will be

welcome if it helps to teach those who are responsible for gold medal awards what modern growers really require. I offer no suggestion as to an alteration of the present methods of the National Rose Society in respect to new Roses, but I commend the last paragraph of "White Rose's" excellent article to the careful attention of its Council.

Mid-Lothian.

GEORGE M. TAYLOR.

[We shall be pleased to publish the views of other readers on this important subject, but we hope they will be as concisely expressed as possible.—ED.]

POTATOES.

UNDoubtedly the Potato is the most valuable of all vegetables grown in a garden. In very small gardens where a fair number of vegetables are to be grown, and only a few of each kind to provide variety, early Potatoes only should be planted, so as to allow of space in the summer-time for

soil is pretty well freed of both small and coarse weeds.

Digging and Manuring.—I need not refer in detail to the work of digging. It will be sufficient to say that the soil must be broken up and the subsoil loosened in the case of new ground, and that a subsequent turning with the garden fork of the top 12 inches will be advisable. Cultivated ground will only need once digging. In every instance well-rotted manure should be used in preference to fresh or green manure. Some growers simply put the manure in the drills or trench and lay the tubers on it, afterwards covering them and the manure with soil. It is much the best plan to dig in the manure evenly over the whole of the ground a few weeks prior to the planting of the tubers in the case of heavy, retentive soils, and then, when the tubers are planted, simply move the top portion to cover the tubers without turning it over and exposing the buried manure. When dealing with light soils, the manure may be applied at the same time as planting is done.

A BEAUTIFUL ALPINE PLANT, SOLDANELLA PUSILLA ALBA. THIS RECEIVED AN AWARD OF MERIT FROM THE ROYAL HORTICULTURAL SOCIETY ON THE 24TH ULT.

several kinds of winter greens to be planted. In larger gardens, early, midseason and late varieties of Potatoes may be grown in quantity, according to the requirements of the cultivator.

Cleaning the Soil.—Some persons say, "Oh! plant Potatoes; they clean the soil better than any other crop." It is not the crop that cleans the soil, but the treatment of the soil necessary to the well-being of the Potatoes. The ground must be well worked before the tubers are planted; the loosened soil is moved during the earthing-up process, and again when the crop is gathered; also, there is considerable hoeing done to keep down surface weeds. A good cultivator does this, and also gets rid of deep-rooting weeds at lifting-time, so that at the end of one year the

It should be spread on the surface and dug in with the soil generally, thoroughly mixing it with the latter. In clayey soils, with which I have had to deal, I have had some trouble in growing tubers with a clean skin. After several seasons of unsatisfactory results I scattered dry lime in the trench, on tubers and soil alike, before covering the former with soil in the usual way. From plots so treated I had Potatoes so clear in skin that they were fit to exhibit in good company. I never measured the lime applied, but used sufficient to make the soil look quite white. The following are good sorts for general planting, and are suitable for a garden of medium size.

Early.—Midlothian Early, a white kidney with white flowers; Sharpe's Victor, white kidney.

light lavender, white-tipped flowers; Sir John Llewelyn, white kidney, white flowers; Duke of York, white kidney, white flowers.

Second Early.—Windsor Castle, white round; Radium, white round, white flowers; British Queen, white kidney, white flowers; Herd Laddie, coloured round; and Mr. Bresse, coloured kidney.

Late.—The Factor, white round or oval, mauve flowers; King Edward VII., coloured kidney, mauve flowers; The Admiral, white round, flowers white; and Up-to-Date, white kidney, mauve flowers.

AVON.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Narcissus Syphax.—This was entered for "garden and cutting." It is a self-coloured flower of rich golden yellow. After Buttercup in shade, but not in form. The stem is long and good.

Narcissus Tita.—A fine, big red cup, also recommended for garden and cutting; and certainly by the length of stem shown, it should prove an excellent garden variety.

Narcissus Sunrise.—This is an incomparabilis sort, with rich scarlet cup and pale creamy perianth segments. Recommended for cutting. These three excellent novelties came from Mr. A. M. Wilson, Shovell, Bridgwater.

Narcissus Eastern Maid.—This in some respects approximates to Sir Watkin, despite the fact that the segments are longer and more pointed, the cup longer and more cylindrically inclined, and the colour a deeper yellow shade. Recommended for show. From Messrs. R. H. Bath, Limited, Wisbech.

Soldanella pusilla alba.—One of the prettiest of its class; a dainty alpine 3 inches high, having heavily fringed, pendent bells of pearly whiteness, slightly stained with crimson at their bases internally. From Messrs. T. S. Ware, Limited, Feltham.

Trillium rivale.—A dainty woodland plant, suited also for cool positions in peat and leaf-mould in the rock garden. It is but 3 inches or so high, quite a miniature in its set, the white flowers copiously spotted with brown. Shown by Mr. James Box, Lindfield, Sussex.

Rhododendron Littleworth Hybrid.—This may briefly be referred to as a giant form of R. argenteum, with larger, longer and whiter flowers. Unfortunately, the anthers had been removed, and

with them a characteristic of the flower had gone. The scarlet-tipped stigma was very conspicuous. Shown by Miss Mangles, Seale, Farnham.

NEW ORCHIDS.

A first-class certificate was granted for an exquisite rich crimson Odontioda named Zenobia. It was shown by F. M. Ogilvie, Esq., Oxford. Awards of merit were made to Dendrobium superbum Huttonii giganteum, shown by W. Walter Butler, Esq., Edgbaston; and to Sophro-Laelio-Cattleya Niobe Orchid Dene Variety, from Messrs. E. H. Davidson and Co., Twyford.

The foregoing awards were made by the Royal Horticultural Society on March 24 at the fortnightly exhibition.

GARDENING FOR BEGINNERS.

DIVIDING AND REPOTTING ASPIDISTRAS.

AMONG the numerous plants grown in pots for indoor decoration, none equals the *Aspidistra* for dark corners, draughty passages and other positions unfavourable for plant growth in the house. It may be safely said, without fear of contradiction, that no other plant is used so extensively. One has only to visit a market nursery and see house after house of *Aspidistras* containing thousands of plants, or Covent Garden in the early morning, to recognise the enormous demand that exists.

Aspidistra lurida, to give our friend its full botanical name, is said to have been first introduced to this country from China in 1822, and two years later, in 1824, a very nice figure was given of the plant in the *Botanical Magazine*, plate 2499. Though of such inestimable value as a foliage plant, the flowers are insignificant, though very interesting to those who love the quaint and uncommon. They appear generally in early spring, nestling among the stalks of the leaves

there is no need for repotting. The plant illustrated has been grown in a room for nine years. During that time it has only been repotted once, and now requires it again. The plant is large enough to divide into two, or, if desired, may be potted on into a size larger pot. For plants growing in a room it is most important to have ample drainage in the bottom of the pots to allow water to pass away freely. Place, as shown in the illustration, one large crock over the hole in the bottom of the pot, next several rather smaller pieces, and on these some still smaller, covering all with a little moss to prevent the soil trickling down and stopping the surplus water from passing out at the bottom. Sometimes when repotting *Aspidistras* the soil is in such bad condition that it is necessary to wash all the old soil away from the roots; in others, when the soil is sweet, only the loose soil need be taken off.

Aspidistras are such good-natured and hardy plants that repotting checks them little, if at all. While most of what has already been written applies to both the green-leaved and variegated-leaved *Aspidistras*, those with the beautifully marked white and green leaves require more care and attention to grow them successfully. As much light as possible must be given them, as in dark corners the leaves are inclined to gradually revert to green, from which in the first instance they have been selected as sports. There is nothing better than a little lukewarm soft water and soft soap for sponging the leaves of *Aspidistras*. On warm, showery days it is very beneficial to stand the plants outside for a few hours. O. A.

SOOT AS LIQUID MANURE.

Soot, used with care, is very valuable in the garden, but frequently it is applied injudiciously, and then the results are unsatisfactory. We only want the essence and not the sediment but there is a mistaken idea that the soot-water, to be of any benefit to plants, must be very black, like the soot itself. This is, of course, the wrong way to use the liquid. If we brew coffee, we use the clear liquid as a beverage, and not the grounds or sediment. Soot must be kept in a box or tub in a dry shed. When a liquid is required, put a peck of the soot in a coarse bag or piece of sacking, tie it up tightly, and immerse in a tub or other vessel containing twelve gallons of water. The bag of soot must be violently moved to and fro twice a day for a week; then use the clear liquid, taking it out very carefully so as not to stir up the sediment.

For the general watering of plants in pots, one pint will be sufficient to mix with a gallon of clear water; for plants in borders, use twice the quantity. In every case the plants must possess plenty of roots, and the soil must be fairly dry before clear water is given, to be followed one hour afterwards with the soot-water.

2.—IF DESIRED, THE PLANT CAN BE DIVIDED INTO TWO OR MORE PIECES.

When the sediment is used and the soot applied in a natural state, the pores of the soil are blocked, and then, through sourness, the roots perish. In the open border, dry soot may be applied, of course, to ward off slugs from young seedlings; but the soot must not be scattered on the foliage. If to be mixed with potting composts, the soot must be stored for at least three months. Never use soot and lime in a closed frame where there are plants, as the lime liberates the ammonia, and, if confined, the leaves of plants are burned. SHAMROCK.

3.—A SECTION OF A POT, SHOWING HOW IT IS DRAINED, AND A DIVIDED PORTION POTTED.

1.—AN ASPIDISTRA THAT NEEDS REPOTTING.

and quite close to the soil in the pot. Less than an inch across when fully expanded, the blooms are buff outside and rich purple inside. The *Aspidistra* gets the name of *lurida* from the poor quality of the flowers, the common name of the Dingy-flowered *Aspidistra* being also sometimes used.

The Best Time to Pot the plants is during March and April, those who are fortunate enough to possess a greenhouse doing such work in March, while April is soon enough for plants which, when potted, must be kept in a window or room. *Aspidistras* will grow in most soils, a suitable compost being a mixture of three parts loam, one part leaf-mould and one part coarse sand. There is no necessity to put *Aspidistras* in large pots, though the roots must not be unduly crowded; the plants will be found to thrive better when the quantity of soil in the pot is not excessive in comparison with the size of the plants.

The question of when a plant requires repotting and how often may now be considered. As long as a plant remains healthy, the soil in the pot keeps sweet, and the leaves are not unduly crowded,

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Cherry Trees in Pots.—This is a precarious crop, and requires careful attention until the stoning period is over. Examine the pots several times daily, and when necessary a good soaking of clear water should be given. The ventilators should never be closed until the second swelling has commenced, and it is far better to let the temperature drop to 40° than to employ fire-heat to keep it higher.

Young Dormant Vines.—Now is the time to plant young dormant Vines. Let every particle of soil be carefully removed from the roots, which must not be exposed to the air for any length of time before they are placed in position, and covered with 2 inches of fine soil from the border, which should have been made up a month ago. When the Vines are planted, water with clear soft water, but only in sufficient quantity to reach the roots. Place a stick to each plant, and, when the shoots are sufficiently advanced, disbudding should be carefully performed, leaving the necessary leading shoots as near the bottom wire of the trellis as possible.

Vine Eyes.—If these were inserted in small pots early in the year, they should now be ready for potting into 6-inch pots. The soil may consist of three parts rich loam, one part leaf-soil, and sufficient silver sand and fine lime rubble to keep the compost porous. Young Vines are easily injured at this stage, therefore potting should take place in the house where they are growing. Support each plant with a stick, and shade for a few days, but as soon as possible the plants should be exposed to the sun. Syringe frequently in order to promote a humid atmosphere.

Plants Under Glass.

Bouvardias.—Early struck cuttings will now require potting, either singly in small pots, or, if struck three in a pot, they may be potted without division, and will make useful plants for early winter flowering. As the season advances and the plants have grown to a useful size, they must be gradually hardened, so that during the summer they may be grown in a well-ventilated pit.

Mignonette.—Plants which are approaching the flowering stage may be watered frequently with weak guano-water, and from now onward they must never be allowed to become too dry at the roots. A further sowing of Mignonette should be made now to provide a succession to those plants which have been cultivated during the spring. Red Monster is one of the best varieties for this purpose; 5-inch or 6-inch pots will be quite large enough.

The Flower Garden.

Montbretias.—If the corms were lifted in the autumn and placed in cold frames, they will now have started into growth, and should be planted out as soon as possible. At Frogmore these roots are lifted each season and wintered in a cold pit. In February, part of the corms are potted, allowed to start into growth, and planted out in April. By this means earlier flowers are obtained, and the supply prolonged by planting dormant corms for succession.

Violets.—If cuttings were taken in the autumn and wintered in cold frames, there will be no difficulty in finding a sufficient number of stocky young plants ready for planting out now. If thoroughly hardened, they may be lifted with a nice quantity of soil to each plant and carefully planted on a well-prepared border. Single varieties may be allowed 18 inches each way between the plants, and double varieties a foot from plant to plant. We grow a large number of Violets at Frogmore, and all of them are struck in the autumn. The old plants are thrown away as soon as the flowering period is over.

The Hardy Flower Border.—Most of the plants have started into growth, and any regulating or transplanting still to be done should be finished without delay, as if dry weather sets in they may suffer seriously. The surface of the border may be carefully stirred with a Dutch hoe. If necessary, the growths of Asters and Phloxes may now be

thinned out, removing the weaker shoots, and others also where they are too numerous. Vacant spots near the front of the border may now be filled with Pentstemons, Antirrhinums, Agrostemma coronaria and Carnations, all of which are well furnished with foliage as well as flowers.

The Hardy Fruit Garden.

Fruit Trees on Walls.—Apricot, Nectarine and Peach trees will still require protection from frost and dashing rain, for, the drier the flowers and foliage are kept in cold weather, the better will be the prospect of a successful crop. While the blossoms are kept dry, they will withstand a considerable degree of cold without injury. As soon as the fruits are set, the trees should be carefully examined, and if any aphides are present, their destruction must be accomplished as soon as possible.

The Kitchen Garden.

French Beans.—These may be sown either in heated pits or forcing-houses, and may be expected to produce pods about the end of May. Plants now in bearing may be frequently watered with weak liquid manure. Syringe twice daily and shut up the house early in the afternoon. Seeds may now be sown in small pots for planting in cold pits about the middle of April.

Winter Greens.—Kales for winter use should be sown with as little delay as possible, and another sowing made about the end of April for use later in the season. Broccoli for autumn and winter supplies should be sown about the end of April.

Seakale.—If Seakale thongs were prepared and placed in a warm border during the winter, the plants should now be ready to put out. Plant in rows 2 feet apart and allow a foot from plant to plant in the rows.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Carrots.—Preparations should now be made for sowing the main crop of this important vegetable. The soil best suited for their successful cultivation is one of a deep sandy nature, but I must not be understood to say that very good results may not be had from ordinary garden soil, that is if this is skilfully prepared.

Sowing the Seed.—On shallow soils it is usually good policy to sow the intermediate or stump-rooted varieties, while Long Surrey and Altringham will succeed best on deep loams. No one, however, can hope to grow Carrots successfully unless the bed has been thoroughly prepared. The seed should be mixed with fine earth previous to sowing; indeed, in addition to this, I have even gone the length of running some sifted soil into the drills before sowing. Needless to say, the seed should be sown thinly, and thin out when the plants are quite small; if possible, in showery weather. It is at this stage that the maggot makes its appearance, and as a preventive I usually give the ground between the rows a dressing of mown grass from the lawn; this is repeated about every three weeks until all danger is past.

Mushrooms.—A bed may now be prepared to give a supply of Mushrooms towards the beginning of June. Should one be cramped for room, the bed may be made up in an outhouse. Beds giving a supply of Mushrooms will be greatly benefited by an occasional watering with rain-water to which a little salt has been added.

Late Cabbage.—All the late varieties of Cabbage, such as Winningstadt, may now be sown, as well as a pinch of seed of Red Cabbage, which is so much in demand for pickling in the autumn.

The Flower Garden.

Bulbs.—The various sorts of bulbs that have been forced should be collected and placed in a frame, where they can be attended to in the way of watering until the foliage is matured. These may be planted out in the autumn in convenient places in the wild garden. Daffodils, of course, may be planted in nursery lines in the garden and forced again in two or three years' time.

Spiræas may be planted right away in some marshy spot, where they soon make handsome plants. Azaleas should have the faded flowers removed, and be kept under cover until the young growth is completed.

Hardy Annuals.—The present will be a suitable time to sow the majority of hardy annuals, particularly those that do not bear transplanting. The sowing of all hardy annuals may be made where they are to flower, provided they are sufficiently thinned. This thinning is important, as it not only prolongs the blooming period, but the flowers themselves are much finer. Such annuals as *Dimorphotheca aurantiaca*, with its gorgeous orange flowers, are extremely effective, and for producing a blaze of colour, perhaps the *Godetias* stand unrivalled. The variety *Scarlet Queen* made a brilliant display here last season. *Phacelia campanularia* is singularly striking with its bright blue flowers, which last a long time in bloom. And what of the ever-popular *Shirley Poppy*, with its endless variety of colour, and that chaste little *Swan River Daisy* that always arrests attention! It would be difficult to imagine anything more showy than that old favourite, *Saponaria calabrica*. Last season I saw this in perfection. The gardener had sown it over some stones and old roots, and when in bloom it resembled a huge cushion of pretty pink, star-like flowers.

Ageratums.—I find it a great saving of labour to grow these from seed rather than propagate by cuttings. They come wonderfully true, and if sown now will last in bloom when almost every other plant is over.

Plants Under Glass.

Begonia Gloire de Lorraine.—By this time the main batch of cuttings should be got in, and it will be found that with the increased sun-heat cuttings inserted now will possibly overtake those rooted earlier. They may be inserted three in a pot in a compost containing a good proportion of silver sand, taking care to make the soil quite firm around the cuttings. Where one cannot command a propagating-case, the same results will be obtained by placing the small pots among half-decayed leaves in a box of convenient size. Cover the box with glass and stand it on the pipes in an early vinery.

Richardias (Arums).—As these go out of bloom, continue to give an occasional watering with liquid manure to mature the crowns for next season's flowers. Let the foliage ripen off naturally, and by no means stand them out of doors until all fear of frost is gone. It is true that at this stage they become unsightly; still, if we expect to procure a supply of these noble flowers, we must give them a chance.

Greenhouse Rhododendrons.—The majority of these lovely Rhododendrons will now be coming into bloom, and as they are usually grown in large pots or tubs and not potted very frequently, they should be given liberal supplies of liquid manure. The variety *Lady Alice Fitzwilliam*, with its exquisite fragrance, is one of the best, and if allowed to grow naturally makes handsome specimens. I find that if the blooms are cut just before the buds open, they travel well and stand quite a long time in a cut state.

Shading.—With the increased power of the sun, all houses requiring shading should be seen to at once, otherwise much damage will be done to the young Fern fronds and Palms.

The Hardy Fruit Garden.

Beyond giving protection to trees and bushes as they come into flower and keeping the ground free from weeds, very little will require to be done at the moment in this department. Apples and Pears, however, may still be grafted where this was not done earlier.

Fruits Under Glass.

Melons.—Those planted last month will now be growing freely, but water should still be given with care, more especially round the neck of the plants. There is still a sharp bite in the air, so that ventilation will require to be done with caution. It will be well to close down the house early in the afternoon, and thus husband as much sun-heat as possible. Seed may now be sown to keep up a succession of ripe fruit.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

MY SMALL ROCK GARDEN: HOW I MADE AND PLANTED IT.

(Continued from page 161.)

WHERE some bay occurs (preferably close to the path edge), it is well to form a "semi-bog" by taking out the soil to the depth of a foot at least, and partially lining the "dish" so formed with clay. If into this receptacle a mixture of peat moss litter (rubbed through a half-inch sieve), leaf-mould, small brick grit and sand is placed, it will accommodate a host of plants which delight in a moist rooting medium, such as *Primulas*, *Soldanellas*, *Erythroniums*, *Polypodium Dryopteris*, and so on. Peat moss litter I have found a splendid material as a substitute for the more expensive peat, and it forms an excellent "sponge." The bales should be opened and allowed to become moist, when the stuff crumbles down to the size of Coconut fibre. It should, of course, be used new—not after it has been in the stable. At some point not far from the eye it is well to form a gently rising piece of ground, where a number of small, irregularly sized beds will accommodate the choicer *Saxifragas*, such, for instance, as *S. burseriana*, *S. rocheli-ana*, *S. Elizabethæ*, *S. marginata*, *S. cochlearis* and its variety *minor*, and *S. Salomonii*, varied here and there with the choice *Woodruff*, *Asperula suberosa*, and the dainty *Linum salsaloides nana*. A little further off, in crevices in rather more rocky ground, *S. lingulata* will display its narrow-leaved rosettes, while in steeply rising, sunny positions *S. longifolia* should be planted in such a way that the rosettes project through a small opening between the stones, and the roots wander away in a semi-horizontal direction behind, amid the gritty, limy compost. In rather similar positions, though in shade, the lovely *Ramondia pyrenaica* can be planted, say, half a dozen in a group, a few inches apart.

The more shady portions of the garden can be planted with the many coloured species of the Mossy *Saxifragas*, such as *S. cæspitosa*, *S. muscoides*, *S. Wallacei*, *S. Clibranii* and *S. bathoniensis*, while their vivid green foliage can be varied by the umbrosa section, such as the type—*S. Geum* and *S. cuneifolia*.

Alpine Pinks.—Among the *Dianthus* family, *D. arenarius* will adorn rocky crevices and drape the adjacent stones with a wee green mantle, which in its flowering season will be a sheaf of white, deeply fringed flowers. In a more choice spot (as well as in the moraine), in especially gritty soil, the narrow, grassy leaves of *D. neglectus* will make a tiny mound, surmounted in June or July with rich, deep carmine blossoms. Similarly in free soil (and, strangely enough, sun) *D. sylvestris* and its dwarfer form, *D. frigidus*, will do well, while on some sunny knoll in quite ordinary, though free soil the Cheddar Pink (*D. cæsius*) will make a welcome patch

Silvery *Saxifragas*, such as *S. Hostii*, *S. Aizoon* and *S. Cotyledon* and its variety *pyramidalis*, can well be employed to garnish crevices between steeply rising rock, and in such positions the arching sprays of white and pink dotted flowers will show to great advantage.

On the sunniest stones Houseleeks can be grown, provided a little soil is given them and they are tended with water until established. The species *Sempervivum arachnoideum* (the Cobweb House-leek) is especially attractive, as it makes silvery hummocks surmounted by rich rosy, star-like flowers. Other decorative *Sempervivums* are *S. Tristii*, *S. fimbriatum*, *S. calcareum* and *S. globiferum*.

Of the *Sedums* or Stonecrop family all are useful, and some especially so. *Sedum Sieboldii*, for instance, with glaucous-coloured foliage, changing to rich rosy copper by the autumn, when its

Stepping Stones.—As every portion must be conveniently reached, it is necessary to place stepping-stones at distances apart, making them as inconspicuous as possible by employing suitable irregularly shaped pieces of flattish stone and "working" them into the design. In my case I made the chief path round the outer portion of the garden, and then arranged several narrow, sinuous tracks more towards the centre (exclusively for my own use), and these were varied by making some merely in the form of stepping-stones, while others were built more solidly and continuous, in the form of a rough, irregular stairway, and, by cementing them at the joints, water, conveyed in a concealed pipe to the highest point, could in the summer-time trickle over them as a miniature cascade.

A Small Pool.—If a tiny pool can be arranged at the lowest part, a considerable charm is

THE COBWEB HOUSELEEK ON A SUNNY LEDGE, WITH ARENARIA CÆSPITOSA IN THE FOREGROUND.

trusses of pink flowers terminate the growths, is most welcome, while *S. Ewersii*, *S. kamschaticum* and *S. altissimum* are attractive.

In hot, sunny positions, where a striking effect is desired, the Sun Rose (*Helianthemum*) in varying colours can be grown, though it is apt to be too large for a small garden; while, if room is available, the dwarf shrub, *Cistus formosus*, with yellow flowers, and *C. purpureus*, with large red ones, are very attractive.

On some steeply inclined portion of the garden in full sun, where there is no trace of lime in the soil, *Lithospermum prostratum* and its variety *Heavenly Blue* make a beautiful cascade of deep green foliage and Gentian-like, blue flowers more or less throughout the summer; while, at the base of such a bluff, *Campanula pusilla alba* can be allowed to ramble, sending up myriads of dainty, 4-inch-high blossoms

added, and near its margin a wet bog can be built by making a bed which will contain peat, sand and leaf-mould in about equal proportions, and such showy plants as *Primula japonica*, *P. pulverulenta* and *P. sikkimensis* will thrive there, while at the extreme water's edge *P. rosea* will revel. If as a background to these there is room for a crown or two of the fine bold foliage of the Umbrella Plant (*Saxifraga peltata*), we can have in miniature the bold effect of a *Gunnera*. As a contrast to the foregoing, either in the water or near its edge, a spathe or two of the common yellow *Iris* gives a beautiful line with its sword-like foliage, though it needs keeping rigidly to a small plant, otherwise it will outgrow its position.

Not only should the garden be decorated with the more or less evergreen plants, but the whole range of dwarf bulbous subjects is open to the

cultivator, and many of these find congenial homes beneath the low carpeting plants. By this means it is possible to have what is practically two crops on the same ground, and the garden may then be flooded in the early part of the year with glorious streaks of blue, where the Glory of the Snow (*Chionodoxa*) spread, while rosy lilac splashes denote *Bulbocodium vernum*, *Scillas* in various colours, early and late flowering species of *Crocus*, and *Narcissi* in varied sizes, from the wee *N. minimus*, only 3 inches high, upwards. Tulips, such as *T. persica*, *T. pulchella*, *T. kaufmanniana* and a host of other similar plants should be employed, and most of them thrive well in the normal compost.

Silvery Leaved Plants.—Silvery foliaged plants, such as *Artemisia vallesiaca*, *Androsace lanuginosa* and *Antennaria tomentosa*, should be utilised to the full, and if pleasingly arranged where their shimmering colour will be backed by some darker foliage, very great use may be made of them. Dwarf conifers, too, aid greatly in suggesting a scale in the garden, and should occupy prominent positions, though never at the highest points of the rock garden, unless they are prostrate growing, such as *Juniperus Sabina* variety *tamariscifolia*. The tiny *J. hibernica* variety *compressa* is dwarf and refined enough for association with the smallest plants, while *Pinus Cembra*, *P. sylvestris nana* and *Picea pygmaea* can be used a little further from the eye, and all seem to thrive in the normal gritty compost of the rock garden.

One final word of warning I should like to mention before closing, and that is to emphasise the desirability of preventing the slightest soil leakage. Often at the point of junction between two stones the insertion of a fragment of rock, either with or without a touch of cement to hold it in place, makes all the difference between success or failure with the inhabitant of the position. Not only does the soil trickle down on to plants below and render them partially submerged, but the leakage rapidly forms a space beneath the higher stones, a matter which should on no account be allowed to occur, and which, when present, almost invariably results in the death of the plant whose roots have wandered in that direction. Firmness, solidity and thorough packing of the porous soil beneath each and every stone should be the watchword of the rock gardener.

REGINALD A. MALBY.

THE EDITOR'S TABLE.

A Specimen Lilac from Dersingham.—From Mr. T. Jannoch, Dersingham, Norfolk, we have received a profusely flowered specimen plant of a single white Lilac. The plant was admirably grown, and so heavily laden with large trusses of bloom that we felt compelled to have it photographed, with the result that it is illustrated on page 169 of this issue. The variety is *Marie Legraye*, well known to be one of the best for pot culture under glass. Mr. Jannoch has a world-wide reputation for Lilacs, and all of the plants sent out from his nursery have been grown for two or more years in pots. This is doubtless the secret of his success, for in order to obtain the finest early Lilac flowers it is absolutely necessary that the plants should be established in pots, and the older the plants the better will be the flowers.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLETS NOT DOING WELL (York).—We find no fungus or insect upon the Violets sent. The great development of leaf with the small amount of flower production suggests that the soil is of too rich a character.

SOWING ZEA QUADRICOLOR PERFECTA (F. H.).—As you have no artificial heat, you may sow the seeds and place in a cold frame in April. Failing this, sow in a warm, sheltered spot out of doors at the end of April or early in May.

THE NEW ZEALAND FLAX (PHORMIUM TENAX) (J. Newbury).—This is hardy in many parts of England. Where this is the case, all that it needs is to plant it out in good loamy soil so situated that it is always fairly moist. If grown in pots, it should be given a compost consisting mainly of fibrous loam, lightened, if necessary, by a little leaf-mould and sand. Under these conditions it must be wintered in the greenhouse or conservatory. A suitable soil for *Lasiandra macrantha* is equal parts of loam and peat, with a good sprinkling of silver sand. The plants should be stopped two or three times during their earlier stages in order to induce a bushy habit.

MANURING BULBS IN GRASS (Kent).—Providing your bulbs appear to be moderately vigorous and the flowers do not deteriorate from year to year, there is no need to apply manure to the grass. We know of many vigorous plantations made twenty years ago which have never been manured since, yet always bloom well. If you do wish to apply manure, however, you may use basic slag and kainit in the proportion of two parts of the former to one part of the latter; use at the rate of 10lb. to the square rod. *Crocuses* and *Daffodils* give good results where the grass is dense, but *Snowdrops* are usually better where the grass is thin. It is doubtful whether *Anemone fulgens* will keep in good condition for more than a year or two, and you would be well advised to carry out a few experiments before making an extensive planting.

HERBACEOUS BORDER AND A PLAN (Anxious).—It is most important that all such borders be set out to a plan, otherwise nothing short of an indiscriminate mixture would result. From the colour point of view it is most essential, and what you have to do is to arrange your plants in informal groups, each group occupying a space of 2 feet or 3 feet, so that the colours will harmonise and not clash. A point to aim at is to avoid arranging in close proximity near akin shades of colour, whether it be blue, pink, violet, purple, rose, salmon, yellow and orange, and so on, stronger and more decisive shades invariably overpowering the weak. By distributing these near akin shades throughout the border in touch with other colours which afford harmony or contrast, a good result is secured. To get a fuller idea of how a border should be set out, you should obtain "The Hardy Flower Book," by E. H. Jenkins, which contains a good plan and much other useful information. It may be had post free from our Publishing Department for 2s. 10d.

MARGUERITE MRS. SANDERS (Santry).—It would not be safe to plant out the Marguerites till the end of May or early part of June. Good garden soil, such as that most suitable for bedding plants, will meet the requirements of this Marguerite. Good clean flowers would doubtless find a ready market. If for quick effect, the plants may be planted from 15 inches to 18 inches apart; but if the object is to readily get between them and pick the flowers, rows 2 feet apart with 18 inches between the plants will not be too much. The cuttings taken now should be fit to plant out in due course.

PLANTS FOR PAVED WALK (N. M.).—You would find the following plants of utility and beauty for the period—July and August—named. All are dwarf growing. When planting, rake out the old soil 3 inches deep from between the stones and apply fresh. Also avoid setting the plants in tufts. By pulling into small portions, a plant or two may prove sufficient to adorn a crevice 18 inches long, from which, in time, they spread naturally.—*Antennaria tomentosa*, *Arenaria balearica*, *Campanula pusilla*, *C. p. alba*, *C. p. Miss Willmott*, *C. pulla*, *C. garganica* in variety, *Hutchinsia alpina*, *Mentha Requienii*, *Sedum corsicum*, *S. hispanicum glaucum*, *S. Lydlum*, and *Thymus Serpyllum coccineum*. A good plant for the bed to appear above the white Alyssum would be *Gladiolus brechenleyensis*. It is scarlet-flowered. Other plants meagre of foliage, flowering at the same time, would be *Montbretias*, though for your district we think the first-named would be the best. The manure you refer to should be excellent for flower beds or, when sifted, for pot plants also. We are pleased you find THE GARDEN of so much assistance.

PLANTS FOR WALL (J. F.).—You have, unfortunately, omitted some important particulars in connection with the wall, and if of ordinary brick, mortar-jointed, and erect, there may be some difficulty in getting the plants to start. The success of the *Aubrietia*, however, gives ground for hope. In the circumstances, so far as we know them, sowing the seeds in the wall would be best, though for a south wall autumn would have been a better time, as the seedlings would be now appearing. Before introducing the seeds, some of the joints should be raked out to a depth of 2 inches, soaking the crevices so formed a few times with water; then, by sprinkling a dozen or two dozen seeds thinly on some moist, stiffish loam, or even clay, the seed-charged soil could be so distributed that the seeds would presently form groups 2 feet or 3 feet across. This principle could be followed throughout, draping or trailing plants, like *Aubrietia*, being kept high, the dwarfier things, like *Erinus*, being set as it were to the middle line of vision. An item of supreme importance is after-attention till the seedlings have taken hold, and the getting of moisture to the roots of plants in a vertically built brick wall is not at all easy. If the wall is of roughly quarried, not "worked," stone, the larger interstices available will render treatment a much simpler matter. In any case, after the distribution of the seed-charged soil, the face of the wall should be daily moistened, as much to hasten the vegetation of the seeds as to afford nourishment later. The following would be of service in the case: *Wallflower*, *Snapdragon* and *Red Valerian* for top positions, if such exist, and where bold plants are required. For the rest, *Aubrietias* of sorts, *Campanula pusilla* in variety, *C. muralis*, *C. garganica*, *Corydalis lutea*, *Dianthus cæsius*, *D. deltoideus*, *D. alpinus*, *D. squarrosus*, *Edraianthus dalmaticus*, *Candytuft (Iberis)*, *Thrift* in variety, *Erinus alpinus*, *E. a. albus*, *Linaria hepaticæfolia*, *Papaver alpinum*, *Saxifraga aizoon rosea*, *S. longifolia*, *S. lantoscana*, *Sempervivum arachnoideum* (seeds or plants), *Edelweiss* and *Zauschneria californica*.

TREES AND SHRUBS.

SHRUBS NOT FLOWERING (Old Subscriber).—Your plants of *Staphylea colchica* and *Xanthoceras sorbifolia* ought to be given the sunniest positions available; then, if growing freely, there is no reason why they should not flower. Do not prune them at all for a year or two, but if very strong shoots are formed, cut the roots round at a distance of 2 feet or 2½ feet from the stems. This, however, is only necessary under exceptional conditions. As a rule, both shrubs bloom freely without trouble, and there is no golden rule by which you can hasten flowering.

TO DESTROY TREE STUMPS (Miss A. C.).—There is no easy means of destroying stumps of trees left in the ground. By uncovering the main roots and boring holes 1 inch or so in diameter in them and filling them with salt, it is possible to kill the stumps, but there is little chance of hastening the rotting process. It is always cheaper in the end to extract roots at the time the trees are felled, for they are a bother for some years if left in the ground which is required for a garden. You can kill the trees and make them suitable for supports for *Roses* by removing a circle of bark 6 inches wide from near the ground; that may be done at once. *Clematises* may still be planted, although it is better to plant them a month earlier. It is not advisable to cut such plants as *Aubrietias*, *Alyssums* and *Armerias* back, but if they are outgrowing their positions, root some young plants in May and destroy the old ones. If your Christmas *Roses* are doing well where they are, do not disturb them. We imagine, however, that the position is rather sunny and dry for them. A moist and rather shady place is more to their liking, but do not change them about from one place to another for flowering. They dislike constant root disturbance. The most inexpensive way to procure broken paving stone for your path would be to obtain it from a local builder or road contractor; perhaps the local surveyor could assist you.

THE GARDEN.

No. 2212.—VOL. LXXVIII.

APRIL 11, 1914.

NOTES OF THE WEEK.

Violet La Belle Parisienne.—At the first glance this double Violet is uncommonly like our old friend Marie Louise, but a closer inspection proves it to be a distinct improvement on that variety. The blooms are larger, have stouter flower-stems, and the colour of the petals is not so red as those of Marie Louise. This is a Violet that is sure to be more largely grown when it becomes more generally known.

Thinning Out Shoots of Herbaceous Plants.—As the stronger-growing plants will now be advancing in growth, they should have their shoots reduced. This will not only strengthen those that are left, but will give less trouble in staking and tying. This will be more necessary with such plants as Phloxes and Asters (Michaelmas Daisies). The latter especially soon get out of hand, and when staked greatly resemble a sack tied in the middle.

A Rare Alpine (*Shortia uniflora grandiflora*).—About four years ago this variety received an award of merit from the Royal Horticultural Society. It is still rare in cultivation and the most exquisite form of a small but delightful genus, of which only two species are in cultivation. The pink suffused, bell-shaped blossoms are fringed, while the ruddy stems appearing above the small crimson leaves render it a most desirable plant. *Shortia uniflora*, native of Japan, is quite eclipsed by its variety *grandiflora* in size of flower, while its close relative, *S. galacifolia*, from North Carolina, is distinguished by a much larger leaf growth and semi-double flowers. The cultivation of *Shortias* is so far imperfectly understood in this country, but a choice position in a damp, half-shady place seems to suit them very well.

Spring Treatment of Violets.—Plants that were flowered in frames or pits might now reasonably be dispensed with, seeing that those out of doors will be in bloom; besides, the frames will be required for other purposes. If a young stock of plants were not rooted in the autumn, it will be necessary to secure the stock from those just being turned out. These semi-rooted cuttings should be planted at once in a specially prepared border somewhere away from the direct rays of the sun, and kept well watered during hot weather until they are well established. As the spider is very troublesome to Violets, the plants should be sprayed over every

afternoon, and an occasional dusting of soot will also assist in keeping them free, besides acting as a fertiliser.

Malmaison Carnations.—Plants that were potted in the autumn will now be growing freely, and if they were not staked at the time, this should be seen to at once. We have seen fine specimens receive a severe check through delaying this work into the growing season. It breaks up

plants soon cling to the objects against which they are planted, and their orange-coloured, tubular flowers appear in great profusion throughout the summer and autumn. Although a perennial, good results can be obtained by treating it as an annual.

Cocoa-Pods at Kew.—A small tree of *Theobroma Cacao*, the Cocoa Tree of commerce, will prove a source of considerable attraction to visitors at Kew during the Easter holidays. Some 8 feet in height, planted out in one of the beds in the large Palm House, four pods are maturing on the tree. These are 5 inches to 6 inches long and about 3 inches in diameter near the centre, with prominent ribs. The colour at present is light green, this gradually changing to yellow as the fruits mature. Each one, when it bursts, is expected to contain fifty or more seeds.

The Sea Lavenders.—There are several hardy and half-hardy species of *Statice*, either of an annual, biennial or perennial character, that are well worthy of cultivation. The paper-like flowers are of great value in a cut state for winter decoration. Apart from this, they are very decorative when fresh, either in beds or borders, while plants of a dwarf habit are quite suitable for planting on the rockery. They are readily raised from seed, which should be sown now in pots and the seedlings pricked off when large enough. The perennial ones can be increased by division, the present time being suitable.

The Night-Scented Stock.—We would remind readers before it is too late about the charm of the Night-scented Stock, which is our usual English name of the plant signalled by the Latin appellation of *Matthiola bicornis*. We have heard of the Virginian Stock (*Malcolmia maritima*) having been purchased in mistake for the real Simon pure, impossible as it seems to fall into such an error. Every evening and all night long the Night-

scented Stock gives out a delightful incense sort of smell, which never seems to pall upon our olfactory nerves. To those who do not know it, we would say that it should not be planted in a prominent position, as its blooms close up during the daytime and give it a woe-begone appearance. It should be sown where it is to bloom, and the seedlings thinned out to about two inches apart every way. It is a plant for close association with the dwelling-house.

SHORTIA UNIFLORA GRANDIFLORA, AN EXQUISITE ALPINE WITH PINK, FRINGED FLOWERS.

the fine web-like roots, which causes the foliage to become yellow. It will not be advisable to commence feeding these Carnations until the pots are well filled with roots.

A Quick-Growing Climber. For covering tree stumps, walls, fences or unsightly objects, *Eccremocarpus scaber* is very useful. Seeds sown now and the seedlings pricked out when large enough will make good plants for putting out by June. With a little assistance the young

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Galanthus Ikariae.—I have grown this Snow-drop for the last six years on a rockery with a full northern exposure, and have always found it quite satisfactory, both in foliage and flower. On March 27 it was in full bloom. This I regard as one of the best of Snowdrops, coming in as it does so late, and so pure in colour, too. I look upon it as one of the best of spring-flowering bulbs.—E. M., *Hants.*

The Horseshoe Fern.—On page 3 of THE GARDEN for January 3 there is a paragraph on the Horseshoe Fern. The New Zealand Horseshoe Fern is *Marattia fraxinea*. It is called "Horseshoe" because of the peculiar shape of the root, which resembles a hoof. It is very rare, and is only known to grow in the vicinity of Mount Egmont in deep gullies in wet situations. It is a very ornamental evergreen Fern, and has fronds of considerable length. The Kidney Fern is quite

be much more extensively grown. I do not find that its cultivation differs from that given to ordinary Tulips, except that it should have very well-drained soil and a sunny position. It is when the flowers are fully open that their glorious yellow centres are fully revealed, this rich colour contrasting well with the pale cream hue of the upper parts of the segments. The flowers are variable, some being much more heavily marked with carmine on the exterior than others.—A. B. ESSEX. [We publish herewith an illustration of a bed of this beautiful early Tulip, which, as our correspondent states, ought to be more extensively grown.—ED.]

Lachenalias for Baskets.—The excellent reproduction of a pot of these charming spring-flowering plants on page 154, issue March 28, should do a great deal towards extending and improving their cultivation. I would like, however, to draw attention to their usefulness for baskets, for though they are excellent when grown in pots, they are also a beautiful sight when in full flower and suspended from the roof in a cool house just above one's head. The method of growing

THE HIGHLY-COLOURED WATER LILY TULIP (*TULIPA KAUFMANNIANA*).

different, being a *Trichomanes*, as stated in the note.—L. STOWE, *Tiakiwai, Tinakori Road, Wellington, New Zealand.*

The Use of Narcissus Seedlings.—The waste in Daffodil seedling raising is proverbial, but we find the M. J. Berkeley seedlings a notable exception to the rule. For some years we have made a practice of crossing M. J. Berkeley with different forms of *Poeticus*, and even after all the best resulting plants are picked out, the remainder afford excellent decorative material. There is scarcely a flower among them that cannot be made use of, as they have fine long stems and ample foliage. Almost all of them come in useful for vases, and a number make fine garden plants.—F. HERBERT CHAPMAN.

The Water Lily Tulip.—I am sending you a few flowers of this charming Tulip, which is listed in most catalogues under its botanical name of *Tulipa kaufmanniana*. I feel sure that if other readers only knew how beautiful it is during the latter days of March and early in April it would

them in this way is very simple. The wire basket, whatever the size may be, is lined with some long moss, pressed firmly on the bottom and round the sides, say, about half an inch thick. Then commence filling with a compost of fibrous loam and leaf-mould, with a liberal addition of sharp grit and a little finely pulverised sheep-manure. Place about as much soil at the bottom of the basket as there is moss, and lay the bulbs upside down at about four inches apart; then cover with soil and gradually fill the basket, at the same time working the bulbs equidistant around the sides, and finishing off on top with a layer to grow upright, so that the bottom, sides and top will all be furnished. When growth is fairly free, a little liquid manure will considerably assist them to produce strong foliage and flower-spikes, especially if alternated with the addition of some approved fertiliser stirred in the water; but care should be taken not to allow any liquid manure to get in the axils of the leaves, or the young spikes may decay.—SOUTH WALES.

Cistus ladaniferus maculatus.—What a useful plant this is for filling up gaps on a south, east or west wall, where a plant of another kind has suddenly died or is becoming too large for its present position! Plants are easily raised from cuttings inserted in a cold frame in September. If put out in the April following, they quickly grow into stocky plants, and can be planted at any time of the year if lifted carefully with a ball of soil attached to the roots. It is a subject to have always at hand ready for an emergency. The blossoms are fully 4 inches wide, pure white, with a dark blood-coloured blotch on each petal. It is no doubt a sport from *C. ladaniferus*, which was introduced from Spain in 1629.—M.

Lilium nepalense.—In THE GARDEN for March 28, page 159, this Lily is said to have been introduced in 1855 from the Central Himalayas. I am aware that this is the date given in different works for its introduction, but it is described as a white-flowered species, which *L. nepalense*, as we know it, certainly is not. It is very questionable whether *L. nepalense* ever flowered in this country till it reached that stage in the nursery of Messrs. Low, then of Clapton, in the summer of 1888. The bulbs were obtained from Upper Burmah during a military expedition into that country. Quite a *furor* was created on September 11 of the year just named, when this Lily was first shown in public at a meeting of the Royal Horticultural Society. It was unanimously awarded a first-class certificate, and though this honour was more easily gained then than it is now, there is no doubt that it was, in this case, well deserved. In the summer of the following year (1889) Messrs. Low received a similar award for *L. wallichianum superbum*, whose name was after a year or two changed to *L. sulphureum*, and as such it is still largely grown. Under cultivation it has proved to be more robust in constitution than *L. nepalense*. After this, from the same source, Messrs. Low gave us *L. claptonense*, subsequently known as *L. primulinum*, and *L. Lowii*, both of which seem to have dropped out of cultivation.—H. P.

Mertensia Mawsonii.—I wonder if any of your readers can enlighten me as to the name of an exceedingly beautiful *Mertensia* which I have on my rockery labelled as *Mawsonii*? It is a dwarf replica of *Anchusa italica* Dropmore variety, grows no more than 5 inches or 6 inches high, and flowers profusely in the early part of March. Its beautiful relative, *M. echioides*, grows here like a weed on the cool side of the moraine. With regard to your note on page 153 of March 28 issue, I cannot agree for a moment that that delightful little flower, *Chionodoxa sardensis*, is a gentian blue, beautiful though it may be. We are becoming very loose in our application of the term "gentian blue." If it is to be used in describing *Chionodoxa sardensis*, we must invent some other colour description for the Gentians. I am further respectfully at variance with you as to the flowering of this little bulb. I have a few hundreds, planted last autumn, which are vastly superior in flower to my established clumps. If *Chionodoxas* are not at their best in their first season, the inference is that the dealer from whom they were purchased sent out second or third class bulbs.—RAYMOND E. NEGUS, *Walton-on-Thames.* [We do not think the experience of Mr. Negus with *Chionodoxa sardensis* is a common one. We have always found established bulbs of this and *C. Luciliae* to give better flowers than newly planted ones. We should be glad to hear what other readers have to say on the point.—ED.]

Tulip Jenny.—As I write these lines a pot of Tulip Jenny is on a table about two yards away from my desk. I had forgotten it was there until I had been writing about a quarter of an hour. As soon, however, as the room began to get a little warmer, delicious puffs of sweetness came with increasing persistence, as much as to say, "You must notice me." Importunity conquered. I went and buried my nose in its pretty rosy (or, to be accurate, pomegranate purple) blooms. What *was* the scent like? A friend suggested Hawthorn. Hawthorn it undoubtedly is. Here, then, is a good name to describe it by to one's friends—the Hawthorn-scented Tulip. Try it next spring and see if this is not right.—JOSEPH JACOB.

Shading Delicate Seedlings.—Now that the sun has considerable power, it is very essential that delicate seedlings of such things as Begonias and Gloxinias should not be exposed to the full rays thereof. This caution is particularly necessary when the sun is obscured only occasionally by passing clouds, as a few minutes' exposure may do a great deal of mischief. At the same time, the young plants should have as much light as possible in order to encourage a good, sturdy growth. This caution against direct sunshine is particularly necessary when minute seeds are sown and covered with a sheet of glass, as the sun quickly sets up an intense heat under the glass and the germinating seeds are simply roasted.—H. P.

Sparrows Eating Yellow Crocuses.—Writing on this subject on page 143, issue March 21, Miss E. A. Patch states that those who have studied the subject of colour will know that red inspires fear in birds and animals. My experience has been that some birds, blackbirds for instance, have little fear of red fruits. I wish they had. What a lot of trouble and expense might be saved if only the birds, through fear, refrained from attacking our crops of Red Currants, Strawberries and Raspberries! I have had red Tomatoes pecked by birds, not because the latter were suffering from thirst, as the garden was on the bank of a river.—COLIN RUSE.

— I have gathered many hints from THE GARDEN, and am pleased to return one which I thought was well known. An enquiry on this subject was made by Miss E. A. Patch in your issue of March 21, page 143. Thirty years ago sparrows tore and scattered my yellow Crocuses, but I stopped them the following season. For that length of time I have had yellow Crocuses planted in the grass, 1 foot wide, on each side of the drive, 30 yards or more long. Last September I planted nearly two thousand Mammoth Golden Yellow on the edges of the drive, removing all old bulbs, and although they have been flowering in their tens of thousands for the past month, not one of them has been pecked by sparrows, which are very numerous. When the Crocuses grow above the surface of the grass and indicate the position of each, from stout twigs I cut 6-inch lengths and place firmly in the ground, two opposite each other, on each side of the Crocuses. Four feet from these I place another pair, and so on, to the end of the Crocus border. Then I get a reel of ordinary black cotton, fasten the cotton to the outer end twig, take it to the inner twig, and so on, outer and inner to the end; then return the cotton fastened to the reverse twigs, and this gives crossed threads every 4 feet. Neither twigs nor cotton can be seen by the human eye when the flowers appear, but the sparrows can see them and for a time keep entirely from the garden.—W. H. W., *Levenshulme*.

— In the issue of March 21, page 143, Miss Patch in her interesting contribution makes note of the damage done by sparrows eating yellow Crocuses. In this and a neighbouring garden, whether in small clumps or large masses, sparrows made no distinction between colours, treating all alike—white, yellow, to deep purple—tearing the petals to shreds in order to get at the reproductive organs of the flowers. Miss Patch mentions that red inspires fear in birds and animals, while yellow appears attractive. From experience during the past three months, I find fowls eat red Camellia petals as greedily as they would green vegetables, probably owing to their thick, fleshy nature. In the summer they have a like fondness for Rose petals.—S. H., *Stirling, N.B.*

Saxifraga burseriana and its Varieties.—With great interest I have read Mr. Raymond E. Negus' very instructive note on the above (page 143, issue March 21). On one point, however, it has wrought confusion in my mind, viz., what is considered to be "the type," of which Mr. Negus speaks in several places? I always understood the form which occurs on the heights around the City of Trient in the Southern Tyrol (hence tridentina) was S. b. major, while the form found on the Swiss mountains was S. b. minor, the former being of a more loose habit of growth, with larger rosettes and larger flowers; the latter of more compact-growing cushions, with smaller rosettes and smaller flowers. The Swiss form is, moreover, distinct in its deeper-coloured flower-stalks and calyces. These two are very distinct forms; probably, however, only as a consequence of different climatic conditions. The warmer Southern Tyrol would naturally produce in course of time a stronger growth of all parts, and the later flowering period of S. b. minor can be taken as the inheritance of its colder home. But now there is a third form found on the mountains of the Northern Tyrol which keeps the middle of the two in character. In the face of these three distinct forms, varying as they do according to their different homes, it is difficult to judge which of them Mr. Negus means by "the type" of which he speaks. The fact that, as Mr. Negus states, S. b. Gloria "does not come true from seed," coupled with his other statement that his particularly large-flowered specimen—if I understand him aright—bears "two, or possibly three, flowers" on the one stem, would point to the probability of S. b. Gloria being a hybrid, for even twin flowers are extremely rare in either of the species. If it were not for this multiple inflorescence, S. b. Gloria might still be considered as having been selected as a giant variety of the tridentina form, for there are great differences as to size of flowers in the individual plants as they occur in Nature. Some of the petals are so narrow at their bases as to leave open spaces between them similar to S. granulata, while others have rounded petals often overlapping each other. S. b. minor has mostly circular and overlapping petals. Among a batch received last year, there is at present also one in flower with crenated edges to the petals; they are deeply lacerated, almost like a Soldanella. It remains to be seen whether this peculiarity will prove constant.—E. HEINRICH, *Planegg, Bavaria*.

FORTHCOMING EVENTS.

April 15.—Royal Horticultural Society's Meeting and Special Daffodil Show (two days).

April 17.—Huntingdon Daffodil and Spring Flower Show.

HARDY ASIATIC PRIMULAS, NEITHER CHINESE NOR HIMALAYAN.

EXCLUDING the Chinese and Himalayan species of Primula, those from other parts of Asia form a valuable series of hardy flowers. Professor Bayley Balfour treated this section in a masterly manner in his papers at the Primula Conference in 1913, and I have been greatly indebted to him for much information respecting these plants. Professor Balfour reckons some forty species, including microforms, as coming into the area. I have had experience of the following, which together form a most interesting and beautiful collection. I am again following Professor Bayley Balfour's classification.

P. acaulis (Linn., Hill).—It will suffice to remark regarding the ordinary Primula acaulis, our native Primrose, that it is indigenous in Armenia, and that there the type does not differ to any noticeable degree from our own wilding. In North Persia a hairy form called heterochroma is to be found, where it was collected by Polak and Pichler and described by Stapf. It appears to be of little horticultural interest. Of more interest, however, is the other microform of P. acaulis, called P. Sibthorpian (Hoffmannsegg), which is P. acaulis var. rubra (Sibthorp and Smith), the red-flowered Primrose which occurs in the Caucasus and spreads to North Persia, as well as in Greece, and which is considered to be the parent of our red, pink, purple, and blue Primroses. In connection with this it may be mentioned that Miller speaks of the purple Primrose as that of Constantinople, that city probably being the medium of its introduction to European gardens. This plant is frequently called P. amoena, which will be referred to under P. elatior.

P. altaica (Lehmann).—So much confusion exists regarding the name of P. altaica that it would be preferable to abandon its use. The name rightly belongs to a form of P. farinosa, called by Pax P. farinosa subspecies davurica var. intermedia. This is the plant figured as P. intermedia (Sims) in the *Botanical Magazine* for 1809. The nomenclature of P. amoena and P. altaica is rather too intricate to discuss in the space available.

P. algida (Adam).—This is one of the Primulas of the Farinosa section and closely related to the Bird's-eye Primrose, P. farinosa, from which it principally differs by its large spatulate, obtuse, finely toothed leaves, its large corolla of an intense violet colour, and, above all, by its globular capsule, which is longer than the calyx. It is not troublesome to grow in some gardens when established, but some find a difficulty in retaining it. P. algida, of which there are several varieties, is of a bog-loving nature, and likes peat and loam in half shade. It ranges from the Caucasus to Afghanistan and the Altai.

P. amoena (Bieb.).—This, the true P. amoena, differs in its general appearance from P. Sibthorpian, mainly by its possession of a distinct scape. It is to P. Sibthorpian what P. elatior is to P. acaulis. It has, of course, no relation to P. cortusoides amoena of gardens. P. amoena has been cultivated since 1831, but so far as I know it is not at present in cultivation in this country. It is a charming plant and ought to come back—a far better thing than many others that are fancied.

P. auriculata (Lam.).—Like P. algida, the above is widely spread in Asia, and occupies the

PRIMULA ALGIDA, A HARDY SPECIES WITH DEEP VIOLET FLOWERS.

same districts to a great extent. It belongs to the section *Auriculata*, and was figured under the name of *P. longifolia* in the *Botanical Magazine* for 1797, t. 392, while Maund gives a good figure of it under the same name. It has a strong resemblance to the other members of the section, and has long leaves and umbels of rose, violet, or lilac flowers. It likes a cool, moist place in the garden in half shade.

P. Bayernii (Rupr.).—The typical *P. nivalis* is referred to later, but one of its microforms, *P. Bayernii* (Ruprecht) may now be mentioned. It is a pleasing form, which has a distinct mealy toothed beading along the margins of the leaves and white flowers, and the calyx is sometimes greenish purple. This is a good grower in moist soil. It comes from the Caucasus.

P. capitellata (Boiss.).—The true *P. capitellata* (Boissier) is not in commerce, and that of gardens is a variety of *P. auriculata*. It is an easy plant to grow if given a moist soil and similar conditions to those of *P. auriculata*. The true plant has farinose foliage and its flowers crowded in a farinose head of rose or purple flowers.

P. Columnæ (Tenore).—This occurs in the Caucasus and Armenia, and is there a rather rare microform of *P. officinalis*, the Cowslip. It has yellow flowers, and is not of special garden interest. *Primula macrocalyx* (Bunge) is another yellow microform of *P. officinalis*.

P. cortusoides (Linn.).—Apart from the confusion existing through *P. Sieboldii* (E. Morren) being often called *P. cortusoides*, with or without the addition of the word "amœna," the true *P. cortusoides* has often been confounded with *P. saxatilis*. The distinction lies in the fact that *P. cortusoides* has very short pedicels, and *P. saxatilis* very long ones. It is a pleasing plant of the *Cortusoides* section, with rose or red flowers, and with petiolate, lobed leaves. The

only sparsely furnished with farina. It is found over a wide area from the Caucasus and through Turkestan, &c. It requires the same treatment as *P. farinosa*.

P. grandis (Trautv.).—Those who expect to find in *P. grandis* one of the finest of the race, as the name might suggest, will be profoundly disappointed with it. The name is applied on account of the large leaves; but the flowers, which are yellow, are small, narrow-petalled, and wanting in grace and colour effect. They are borne in umbels on tall stems. This species, which belongs to the section *Svedinskya*, is a lover of moisture, and should be planted by the side of a pond or stream. *P. grandis* is a native of the Caucasus.

JOHN MACWATT.
Morelands, Duns.
(To be continued.)

whole plant is more or less covered with a silky pubescence. It is easily grown in common soil.

P. darialica (Ruprecht).—A rare little plant, after the fashion of *P. farinosa*, and a native of the Caucasus. The plants included under the name appear to vary, and this is in accord with Pax's descriptions of the species and its forms. The flowers are rose and the leaves mealy, but sometimes free from farina. Moist soil or pots.

P. elatior (Linn., Hill).—Of the microforms of *P. elatior*, the Oxlip, which occurs in the Caucasus and Armenia, mention may be made of *P. cordifolia*, (Rupr.) and *P. Pallasii* (Lehm.), though not of special garden worth. They are distinguished mainly by the form of the leaves.

P. davurica (Spreng.).—This is a microform of *P. farinosa*, which has rose or rose lilac flowers, and of which there are two or three varieties. The leaves are, however, without or

THE ROCK GARDEN.

THE GREAT HEPATICA.

(ANEMONE ANGULOSA.)

THIS is one of the many spring-flowering Anemones that should be given prominence in the rock garden. The flowers are clear sky blue, like those of the Hepatica (*Anemone Hepatica*), but much larger; there is also a white form, somewhat uncommon, named *alba*. This plant needs a deep, light soil; in cold, damp situations the plants are inclined to lose their foliage. A very effective way of growing Hepaticas in the rock garden is to plant them among creeping Sedums or Mossy Saxifrages, the green carpet adding materially to the effect. They may also be used as an edging to beds of spring flowers or along the margins of woodland walks. This plant is quite often met with under the name of *Hepatica angulosa*. It is perfectly hardy, and may be increased by seed or by division of the roots.

SEDUM PULCHELLUM.

AMONG all the numerous members of the Stonecrop family, I know of no more attractive species than this. It is indeed a most charming plant, possessing all the attributes of a really good rock garden subject, and well worthy of a position on the most select rockeries. It is an evergreen species, producing numerous growths from a central tuft. As these lengthen they very much resemble the

ANEMONE ANGULOSA, A DAINY LITTLE PLANT FOR THE ROCK GARDEN IN SPRING.

young growing shoots of a Spruce Fir, their narrow, pointed leaves being about an inch in length. These, when mature, assume a most beautiful shade of red, and the contrast between these and the young, fresh green growths pushing up from the base gives the whole plant a most delightful appearance. The branches, which are slender and from 3 inches to 6 inches or 8 inches in length, are trailing in habit, but ascending at the tips, upon which are borne the three to five—usually the latter—branched cymes of beautiful rosy purple flowers, arranged closely together in two rows on the upper surface. I may say that frequently flowers are produced from the sides of the branches, but it is more usual for them to be borne only upon the tips. The “arms” of the cyme vary from $1\frac{1}{2}$ inches to $2\frac{1}{2}$ inches in length, although I have known them to measure quite 5 inches—that is, 10 inches from the tip of one arm to the tip of the one opposite—but that is unusual. In outline they bear a marked resemblance to a starfish. Its season of flowering is a long one, a succession of flowering shoots continuing to push up from the base until checked by frost. Its cultivation is of the simplest. Here I have it growing on a rockery in full sun in a compost of loam and limestone chippings in about equal proportions, with a good layer of the latter on the surface.

It grows very rapidly. The rockery upon which it is growing was rebuilt a year ago and six or seven small tufts planted on a ledge behind a stone, and these have developed into a patch about two feet across. Like most Sedums, it is easily propagated. The flower-stems, as they lie upon the ground, emit roots, and the numerous growths which develop along its whole length offer a ready means of increase. J. D. HALLIBURTON.

Botanic Gardens, Bath.

THE ALPINE FLAX.

LINUM ALPINUM, the Alpine Flax, may have few or none of the virtues and utilities of the common Flax, but it has beauties which certainly commend it to the lover of dwarf flowers for the rock garden. This pretty Alpine Flax is of a neat habit of growth—its height is rarely more than from 6 inches to 8 inches, it has light and elegant foliage of the most fairy-like order, while its blooms are of a delightful shade of blue, and, when in bloom in summer, almost cover the plant with their delicate beauty. Nor is it difficult to cultivate, especially when a plant has once become established. It likes a free, open and dry soil, and to be planted in a sunny place. Yet it seems to appreciate a fair amount of moisture in summer; and a good plant in the writer's garden, which has been placed on the lowest terrace of a little rockery, where it receives a good deal of the surplus moisture from above, flourishes excellently and gives a sheet of bloom on its fragile stems. *Linum alpinum* can be raised from seeds, which are best sown at this season under glass and the seedlings pricked off as soon as they can be handled into other pots or boxes about two inches apart and grown on a little before planting out. It can also be increased by dividing established plants in spring. S. A.

DAFFODIL NOTES.

GROUPS AND FLOWERS AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW ON MARCH 24.

(Continued from page 168.)

It is quite unintentional on my part, but I find the three groups which will occupy my attention in these notes have a common denominator, one which, subjectively considered from the putter-up's point of view, is irritating and perplexing; but which, objectively, from the walker-about's standpoint, is sometimes attractive and inviting, and sometimes, using the word in its ancient Tulip sense, bizarre. More difficult far than the most abstruse proposition of our old schooldays' friend, Mr.

NARCISSUS WHITE KNIGHT, A REFINED WHITE-FLOWERED VARIETY. NOTE THE LENGTH OF THE TRUMPET.

Drive-me-mad Euclid, is the problem of how to be original in the display of Daffodil blooms in and on a something that by the necessity of the case might almost be called “a line,” which, as the aforementioned author tells us, is “length without breadth.” The little group of which I am about to write has made the attempt.

For some time past we have been familiar with the flattened crescent of Messrs. Cartwright and Goodwin, with its *Isolepis* clad tier upon tier. Now we have Mr. Bourne and Messrs. Barr and Sons essaying the same hard task. The latter firm gave us a graceful undulation, clothed in the best of taste. It was a fine effort. Mr. Bourne had a more set piece. A half circular tiered stand occupied the middle of his display, at either end a quarter one. The two spaces between were flat, with a large Bamboo vase

raised upon a square pedestal in the centre of each. The idea was ingenious, and is a decided “break”; but the introduction on this occasion of a brown background when all the rest was covered with green seemed to me just to spoil it.

And now for the individual flowers. Beginning with this group of Mr. Bourne's. Here were numerous examples of good standard varieties, the only new one being a very pretty little round white-perianthed *Barrii* with a large Poet-looking eye. It was not named. Then there was *Millie Price*, a nice little pale green-eyed Poet; also *Lemon Belle*, a pale lemon, long vase-shaped variety, which Mr. Bourne tells me does splendidly with him at Bletchley; also *Red Chief*, with its wide, deep orange red rimmed cup, as good in the open as in pots, cheap at its price; also *Cygnets*, the late pale bicolor trumpet, which always looks

effective in a group, possibly because of its clear-cut trumpet. Then there was *Judge Bird*, a large pointed flower of the same section as *Cygnets*; also *White Knight*, to me the very acme of refinement in pure white trumpets, a flower that at its best can, in sporting parlance, show its heels to any other. Fancy this gem being grown in pots! It is still (1914) listed at four guineas; but, remember, last year it was seven.

Among Messrs. Cartwright and Goodwin's flowers three were fine novelties. I write of them in the order in which I would like to have them. First, *Chryse*, a cross between *King Alfred* and a *Campernelle Jonquil*. It might have been the true *Jonquilla odorus Campanelle* seen through a big magnifying-glass. It featured it so much, especially as it bore two blooms on a stem. I do not think I have ever seen anything like it. It gets away from the Buttercup style, with which we are now becoming familiar. Its dimensions are as follow: Diameter of perianth, $3\frac{1}{2}$ inches; length of cup, $1\frac{1}{2}$ inches; diameter of its top, $1\frac{1}{2}$ inches. If I could not have *Chryse*, then give me *Supremacy*, a pale yellow *Ajax*, distinguished by its long, delicate-looking trumpet and its pointed perianth segments. It is a seedling from *King Alfred* crossed with the *Rev. D. R. Williamson*. As it is one of the first of their home-made seedlings, I take the opportunity of congratulating the firm upon their achievement. Measurements: $4\frac{1}{2}$ inches by $1\frac{1}{2}$ inches by $1\frac{1}{2}$ inches (this width only at the very top). Failing these two, I would then go for *Gold Wolf*. This is another *Ajax*, but the very opposite in almost every detail to *Supremacy*. It is

deep yellow in colour, is a round more than a pointed flower, and is decidedly squat-looking, as the measurements of its trumpet will show. Length of same, $1\frac{1}{2}$ inches; width at mouth, 2 inches. We want these differences in general appearance, and of the thick set style this is a good example. *Ivorine*, a great favourite of mine (Section 4), looked very well among some yellows. I also thought *Amphion*, a new buff and orange double, very attractive; perhaps it was owing the similarity of its shape to that of *Argent*.

Now I come to Messrs. Barr and Sons' exhibit. It was beautifully arranged and staged. I doubt if I have ever seen a large group that on the whole I liked better. The pot plants seemed a little discordant, and I wished they had not been there, or, at any rate, had been put at the extreme corner end. There were a goodly quantity of seedlings, all

under numbers, and for the most part only represented by one or two blooms. These it is impossible to describe. Of the named varieties, the following, for one reason or another, deserve honourable mention: Sunrise was before the committee, and received an award for cutting. The yellow ray in each petal which shocked the purists when it first appeared has been "sized up" by the public as one of its charms. It says much for it that every retail firm wants to buy it. Isis is a drooping bloom, which Mr. Rudolph Barr told me came out of the same seed-pod as King George V. and Miss Willmott. It is a sort of pale yellow King George V., which in turn is Miss Willmott made into a better show bloom than it is. Diameter of flower, $3\frac{1}{4}$ inches; diameter of petal, $1\frac{1}{8}$ inches; width of cup, three-quarters of an inch. Messina, which was represented by one perfect bloom, is a borderland plant. Up to now the Poet section has claimed it, and it appears in Messrs. Barr

on. Twenty years back was that was the year of "naughty" Weardale's first public appearance; only "naughty" because it was so dear (*twelve guineas*). "Naughty," as the little boy called the bird which his father had missed after a very easy shot. The bottom of my paper has "cut me off." I am once more before Sensation. It has been grown in pots, and looks well among all the new-comers. A half-crown will buy twelve. A half-crown might be worse spent.

JOSEPH JACOB.

FORSYTHIA SUSPENSА.

In the latter part of March and early April Forsythia suspensa is one of the most beautiful of all hardy shrubs, for at this season its long, drooping branches are wreathed in bright yellow, bell-shaped flowers. It is a shrub that can be depended upon to flower well every spring, and many pretty effects can

FORSYTHIA SUSPENSА OR GOLDEN BELL, ONE OF THE MOST BEAUTIFUL OF EARLY FLOWERING HARDY SHRUBS.

and Sons' 1914 list as such. But I think this is wrong. For one thing, the perianth is not that dead white which is the feature of all others of a true-bred Poet; and, secondly, its early flowering (it came from the open at Penzance) is rather a hint to doubt it *a priori*. The solid orange brick red eye, surrounded by a round, imbricated perianth, give us a very pretty bit of colour; but not, I think, a Poet.

A vase of Sensation brought back old times to my memory. I can remember the days when it ranked high in our estimation. Twenty years ago it was priced at 4s. 6d. each, which, in proportion to the present charges for new varieties, was a high figure. Mme. de Graaff was but £3 and Glory of Leiden a guinea; Gloria Mundi, 30s.; Duchess of Westminster, 4s. 6d.; and so

be obtained by carpeting the surrounding ground with Chionodoxas, Grape Hyacinths or other spring-flowering bulbs. *F. suspensa* is a loose-growing shrub of more or less rambling habit, and it does very well against a wall, railing or fence. It is perhaps seen to the best advantage when grown as large isolated bushes on lawns, or, in a semi-wild part of the garden where the long shoots are not too restricted for space. The bush illustrated on this page is growing in such a position, and here the arching shoots, which are profusely flowered, droop down for 8 feet or more and root into the soil.

Overcrowded shoots should be thinned out after flowering, but one should avoid pruning this shrub like a hedge, which is to deprive it of its truly graceful and drooping habit.

ROSE-GROWING IN TOWN GARDENS.

Standard Roses add greatly to the attractions of a town garden, but they should be employed with moderation, as a too free use of them tends towards formality, which it is generally desirable to avoid. They are useful aids to effect, and enable the gardener to obtain raised and isolated patches of colour at certain spots where it is not convenient or expedient to plant climbers. They have also the advantage that the blooms may be examined with greater ease and without the discomfort of stooping. On the other hand, one cannot expect such good blooms as from dwarf trees, and very rarely is it possible to get them up to exhibition size without hampering the development of the head. Only the most vigorous kinds are suitable for growing as standards, and even with these there is often a large percentage of losses. One frequent cause of this is that Briars are often budded before fibrous roots have formed, and club roots alone will seldom provide a plant with sufficient nourishment after being transplanted. The gardener should make a point of seeing standard trees before buying them, and select only those with plenty of top growth, which will indicate a fair proportion of fibre at the roots.

Tall Weeping Standards are increasing in favour. They make effective ornaments on large lawns, though I think their use is rather to be deprecated in small gardens. I have seen them planted against a closely boarded fence, the growths tied along trellis-work at the top, and with low-growing climbers covering the fence beneath. The arrangement was certainly attractive, but the cost makes one a little chary of recommending it. The choice of varieties in weeping standards is generally limited to the wichuraianas, with which they are usually budded; but Climbing Mrs. Cutbush should make an ideal Rose for the purpose, for it possesses the enormous advantage of being quite perpetual.

Ordinary Full Standards, with stems from $3\frac{1}{2}$ feet to $4\frac{1}{2}$ feet long, are generally employed for planting at intervals around the edges of lawns, and this is perhaps the best use to which they can be put in town gardens. They may also be planted down the centre of beds of other Roses from 4 feet to 6 feet apart; but beds of standards by themselves never look well, and they force upon the onlooker an inevitable comparison of stems, which creates anything but a favourable impression. From their very nature they should be isolated, for grouping only tends to bring out ugly points, which are lost sight of when they are planted with discretion.

For giving additional height to the centre of a bed, half-standards are to be preferred, and stems from $1\frac{1}{2}$ feet to 2 feet long will amply suffice to raise them above the level of suitable companion trees. One frequently hears it stated that some Tea Roses do best on standard stocks, and certainly there are some varieties of spreading habit of growth and with blooms inclined to droop which may be better admired if grown in this way, and, moreover, the flowers will not become splashed from being too close to the ground during heavy rains. But I do not think there are any kinds which actually grow better as standards, unless it be that the gardener has not lightened his soil sufficiently to suit the warmth-loving roots of the Teas. A point of importance

with standards is to keep the stems clean and free from moss, a simple enough matter if the grower will give them an occasional wash with fungicide. It is also most important to protect all cut parts near the base, so as to avoid injury from sawfly larva, and painting with enamel, as recommended in a former article will accomplish this. The two varieties better than all others for standard Roses are Hugh Dickson and Frau Karl Druschki, and, having regard to the difficulty of obtaining really good heads in the average town garden, most growers would do well to rely entirely upon these two sorts. Others which may be grown with fair, if not equal, hopes of success are Mme. Abel Chatenay, Caroline Testout, Mme. Ravary, Lady Ashtown, J. B. Clark, Joseph Hill, Mme. Melanie Soupert and La Tosca. P. L. GODDARD.

A NEW SUNFLOWER. COLOURED PLATE 1491.

AT the great show held in the grounds of Holland House, Kensington, at the commencement of July last, Messrs. Sutton and Sons, Reading, exhibited for the first time a Sunflower, with a rich chestnut red band surrounding the disc. This proved a great attraction to the numerous visitors at that exhibition. On Tuesday, July 29, a large exhibit of the flowers, sent up from the firm's trial grounds at Reading, was staged at the fortnightly meeting held in the Royal Horticultural Society's Hall, Westminster, and gained the distinction of the society's award of merit.

It is a very striking flower, with a broad band of chestnut red round the base of the yellow petals, and is the result of a cross made between *Helianthus annuus* (the common annual yellow sunflower) and *Helianthus lenticularis coronatus* (the common wild Sunflower of North America) by Professor Cockerell of Boulder University, Colorado, who handed over his stock to Messrs. Sutton for development. The cross was made four years ago, and the strain has been under observation since, and is now well fixed. There has been no previous record of this colour in the popular *Helianthus annuus*, which is such a well-known and favourite annual in English gardens. Messrs. Sutton furnish us with the following description of the new sunflower:

"A 'Gaillardia Sunflower' is a very apt description of this brilliant new variety. It is of the true *Helianthus annuus* type, and we do not know a more stately or impressive subject for tall borders. As a dot plant, or grouped in the foreground of shrubberies, it is particularly telling. The plant is of free branching habit, producing numerous well-shaped, dark-centred, brilliant flowers, banded with bright chestnut red, mostly merging to yellow at the tips of the petals. The smaller and medium sized flowers, when cut with long stems, make a unique and magnificent decoration in large vases, and show to great advantage under artificial light.

We are indebted to Messrs. Sutton and Sons for the use of the autochrome from which our coloured plate has been prepared.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE FIRST BREAK: STOPPING PLANTS.

JUDGING from the present condition of the plants, there seems to be a good prospect of free and healthy growth, at least during the first half of the Chrysanthemum season. The plants make rapid progress up to the stage when the first bud appears and causes the break. Then they grow more slowly for a couple of weeks or so; this is caused by the check through the formation of the bud. It is natural, and is all

but the earliest sorts, making a natural break in April or early in May, may show another bud early in June. The resultant growth from the second break in June will bear a good bud fit for "taking" in August, and I have found that such crown buds generally appear from August 15 to August 25, and they develop very kindly.

It is necessary to stop some late varieties, else the work of the year would be thrown away. We will take that well-known sort, the Hon. Mrs. Lopes, as an example. If the plants were allowed to grow naturally from the cutting stage, their blooms would be practically useless, having open centres full of seed florets, with about two rows of guard petals. The blooms, such as they would be, would open at the end of November. If, however, the plants are stopped in April, the resultant shoots would bear crown buds from July 25 to August 10, and they would develop into very fine, full blooms, rich in colour and refined in form, about the first week in November.

If we take the old variety Mrs. A. T. Miller, which is a naturally early flowering one, we find the best results from non-stopping; that is, the plant must be allowed to grow in spring until a bud appears—it generally comes during the first half of May—then the resultant shoots are grown on and, in due course, bear the first crown bud, which usually appears early in August—an ideal date for the variety being August 15—but the buds often show quite a week earlier. This cannot be helped, and so everything must be done to retard the development. Although the repotting of the plants does not interfere with the growth, if done at the time the bud shows that causes the first break, it does if carried out when the tops are pinched off the plants. Stopping, therefore, should be done about a week before or a week after the repotting takes place. AVON.

DENDROMECON RIGIDUM, A HARDY TREE POPPY WITH
BRIGHT YELLOW FLOWERS.

A BEAUTIFUL TREE POPPY.

DENDROMECON RIGIDUM.

THE Poppy Order includes many interesting and beautiful garden plants. The genera *Meconopsis* and *Romneya* provide instances of flowers possessing rare and refined beauty. *Dendromecon rigidum* is another example, and if only better known it would be far more extensively grown. It is appropriately termed a Tree Poppy, since the growth is woody and the blossoms are unmistakably

like those of the Poppy tribe. The flowers are bright clear yellow, with two caducous sepals, four petals and numerous stamens; the leaves are lance-shaped. When planted in a light, rich, loamy soil against a sunny wall, it forms a large bush, and produces its flowers in May and early June. Like most other members of the Poppy tribe, this plant is very impatient of root disturbance, and when once established it ought not to be removed. This delightful shrub occurs wild on the summit of the mountains near St. Barbara in North America, and it is interesting to record that between 1831 and 1833 a number of plants were sent home by David Douglas, at that time plant-collector to the Royal Horticultural Society.

I will very briefly explain. If a bud shows on April 15 and it is found that the particular variety does best when topped about that date, then the shoots growing after the natural break will be better than those following the stopping or pinching of the plant on the same date, because the growths following bud formation are always more likely to bear flower-buds at the right time in August.

The very latest varieties will rarely show another bud before the one that appears early in August

like those of the Poppy tribe. The flowers are bright clear yellow, with two caducous sepals, four petals and numerous stamens; the leaves are lance-shaped. When planted in a light, rich, loamy soil against a sunny wall, it forms a large bush, and produces its flowers in May and early June. Like most other members of the Poppy tribe, this plant is very impatient of root disturbance, and when once established it ought not to be removed. This delightful shrub occurs wild on the summit of the mountains near St. Barbara in North America, and it is interesting to record that between 1831 and 1833 a number of plants were sent home by David Douglas, at that time plant-collector to the Royal Horticultural Society.

COLOUR EFFECTS IN THE GARDEN.

IN attempting to comply with the request by a correspondent whose note appeared in a recent issue, on colour effects and colour arrangements, I wish it to be understood that in no sense do I claim to be an expert, not even in the sense that Donald Beaton, in the middle period of last century, was allowed to be, though he himself usually attributed his successful efforts in floral arrangements to the good taste of his mistress, Lady Middleton. The people who are successful floral colourists are regarded as the possessors of a natural instinct for colours. In a sense that is, no doubt, true, just as there are people who seem instinctively to mark the points of a sheep or a cow, or as a scholar takes to mathematics or languages.

Some of the prettiest floral effects I have ever seen have been in cottage gardens, and composed of the cheapest material, the efforts of folk whose sole education has been picked up by observation and a few years' experience. But a little plot of

pleasing arrangements, and also those which, otherwise good, are spoiled by some insignificant detail, though no detail is insignificant that spoils a whole. Still, it is often noticeable that an indifferent scheme of colouring is rendered so by perhaps one colour which clashes with or depresses the tone of all the others; and, of course, a note made of that will for all time be a warning. It was just such an inharmonious note in the coloured plate that appeared in the January 3 issue that caused me to pen the few lines which has brought about the writing of this.

The introduction of white weakened the strength of the pink and deeper tones, and the deep blue in the foreground intruded a discordant note which was harsh to a degree. I do not agree that blue should not be used with pink, especially if not a pronounced blue, and, in the scheme in question, had it been placed in the background it would not have been displeasing, even if superfluous. This, it will be observed, relates as much to the proper distribution of colours as to their association, and leads to a brief consideration of methods of distribution which are popular at the present time. In the coloured plate of January 3 the distribution is shown to be in longitudinal lines,

PLAN OF A TERRACE GARDEN ARRANGED FOR COLOUR EFFECT.

garden is manifestly not to be compared with that containing a series of beds and borders, and no one would expect a cottager, however successful in furnishing his own garden, to be able to work out with any degree of success a colour scheme for a gentleman's garden. But the point I wish to emphasise is that no one need despair of success who with all his mind attempts the higher flights.

There is much diversity apparent even among those whose colour sense is largely developed. Some know good colouring, are able to recognise good points and bad ones, distinguish why they are good and bad, and detect inconsistencies which some to whom one would attribute the possession of equal accomplishments fail to detect, though they have the feeling that this is right and that is wrong. Nor can these make anything of details. They usually are copyists of what is good in other people's gardens, and judging from the remarkable similarity to be found in floral arrangements in particular localities, it is obvious that they must form the great majority. Copying, at least to some extent, is perhaps unavoidable; but it is more to be commended in the breach than in the observance. Much better is it to make abundant notes of

a method which has much to recommend it. The *coup d'œil* is harmonious, whether the component parts are kept to separate lines or the colours most nearly approaching each other are mixed together. It is, moreover, possible to employ a great number of colours, not merely those from pink to red, but selected yellows at one side and blues at the other, without lowering the general effect in the slightest degree. It must be obvious how very advantageous this is in gardens of no great extent where variety has to be considered. There are many people who esteem a collection of hardy plants mainly, and in all available colours, as still the most attractive, and in this form, as an adjunct, can be studied to the highest degree and used to the greatest extent. Enough, however, has perhaps been advanced on mixed borders in the series published early in the year.

Equally, if not more, important is the treatment of the strictly geometrical flower garden. Here, there is always the personal equation to be considered, and the likes and dislikes of the individual cannot be disregarded. But where there is a free, or a comparatively free, hand, the problem should be considered whether the

most satisfying scheme be that which divides the colouring into sections with, perhaps, little connection each with each, or a scheme which subordinates the whole to a dominant note. The latter, I am inclined to think, is the more æsthetic. It is not so much a question of variety, whether of colour or of form, in this case as its quality as a reasoned whole. In the plan shown the beds B B are of ornamental stonework raised 3 feet above the level of the lawn. These are furnished permanently with rose-coloured Roses, are carpeted with *Nepeta Mussinii*, and give the keynote to the colour scheme. The other beds this season are to be as follows: A A—each of 800 square feet superficial—isolated masses of deep rose Larkspurs, which attain a height of 6 feet to 7 feet, the interspaces *Verbena venosa*, and a broad rim of dwarf *Ageratum* round the outer portion. The eight small beds (C), tall and dwarf *Ageratums*; the H, cream; the long, narrow beds (D D), intermediate and tall *Antirrhinums* in light pink to carmine pink; E E have a line of *Kniphofia Uvaria* along the edge next the wall (I), and the other portion furnished with intermediate and tall, but mostly tall, *Antirrhinums*, of various shades of yellow, apricot, and a touch of red. F is a mixed border in which stronger colours will be admitted. G, on the other side of the cross walk, will come so far into the scheme, and the chief plants will be tall dark blue Larkspurs, with *Statice sinuata*, mauve, in the interspaces and dwarf *Ageratum*, as in A.

While engaged in writing the foregoing, a note was received from a gardener regarding the planting of a series of eight beds. The letter raises an interesting point. He proposes employing *Verbena venosa*, with Orange King *Antirrhinum* or *Calceolaria amplexicaulis* to brighten it. The first of these two is not suitable; the other would do were it the chief, and the *Verbena* the subsidiary plant. I myself am furnishing a detached border with *Verbena venosa*, a low wall at the back to be clothed with *Nasturtiums* of nasturtium colour, and a line in front of a faint yellow or amber-coloured Snapdragon. Neither will lower the tone of the *Verbena*, but, on the contrary, will enhance it, and thus the *Verbena* will never be other than the chief plant in the scheme. With the *Calceolaria* there would always be a danger of it losing that position. The same thing happens when yellow is associated with a true blue, such as *Salvia patens*, and I have seen a block of the latter spoiled owing to the introduction of a few bright yellow Snapdragons among it. It will be seen that few of the beds above noted have edgings, and that these harmonise with the plants in the other beds. Edgings are by no means essential, and, unless very carefully selected, they are a source of weakness, if no worse, in a general scheme.

In 1913, edgings were more freely used than it is proposed they will be this year. The H was the same cream shade, but A A were a mass of Snapdragon Fire King and *Calceolaria amplexicaulis*, dropping in stature to the edge by the inclusion of *Cuphea strigillosa* and *Chlorophytum elatum*, the dwarf variety with soft yellow variegation down the middle of the leaf. C C were of pink Snapdragons with variegated Ice Plant edging each; D D, grey-blue to true lavender; E E, deep crimson tall *Lobelia* intermixed with common Cornflower, and a narrow edging of *Lobelia Waverley Blue*. There was a line at the furthest edge of the darkest blue Larkspur, but the plants were destroyed when young by game.

Tynninghame, N.B.

R. P. BROTHERSTON.

GARDENING FOR BEGINNERS.

SEASONABLE WORK AMONG ANNUAL FLOWERS.

THE Easter holidays come at a most convenient time this year for lovers of gardening. Among the numerous operations to be attended to at this date are sowing of seeds of annuals and pricking off seedlings, raised from seeds sown in the autumn and under glass

1.—SPRINKLING SEEDS ON FINELY SIFTED SOIL IN A WELL-PREPARED SEED-BOX.

during February and early March, into boxes or transplanting outside.

Sowing Seeds Under Glass.—The weather, whatever it is, will not interfere with the amateur gardener sowing seeds in shallow boxes, pans or pots, as this can be done under cover in a shed or greenhouse. For obvious reasons shallow boxes and pans are preferable to pots, for though we can put ample drainage in the bottom of the pots to compensate for their greater depth, the area of the surface soil for sowing the seeds is comparatively small unless large, clumsy pots are brought into use. A larger area of soil permits of thin sowing, which is most essential, for not only is it a waste of seeds to sow thickly, but seedlings crowded in a small state are soon ruined. A very convenient size for the boxes is 14 inches long, 9 inches wide and 3 inches deep. Old kipper boxes from the fishmongers are very suitable. Should one have only a few seeds of a particular plant, divide a box in half by placing a stick across the centre, and sow two kinds of seeds in one box, taking care to choose sorts which will take about the same time to germinate.

2.—THE SEEDLINGS SHOULD BE PRICKED OFF WHEN LARGE ENOUGH TO HANDLE.

A suitable compost to fill the boxes consists of two parts loamy soil, one part leaf-mould, and one part coarse sand. Pass this through a quarter-inch mesh sieve, using the rough stuff remaining in the sieve to put in the bottom of the boxes for drainage. If the boxes are filled lightly with soil and the surface is then pressed down moderately firmly with a flat board, the soil will be about the right distance from the top. To obviate the necessity for watering the seeds as soon as sown, it is better to water the soil when the boxes are filled, and leave them to drain a few hours before sowing.

The depth to cover the seeds depends on their size. The smallest need only have a slight dusting of fine silver sand. Larger seeds—Asters, for instance—require a thin covering of very finely sifted soil. Where to place the boxes after sowing depends on the convenience of the grower. A shelf in a cool or cold greenhouse, a hot-bed and a cold frame are all suitable. Without even these advantages the beginner need have no qualms; cloches, hand-lights, or a sheet of glass placed over each box is sufficient protection to induce the seeds to germinate quicker, and affords them more protection than is possible outside. To prevent the surface soil drying up rapidly, cover all seeds with paper till germination commences.

Sowing Seeds Outside.

Without going to an endless amount of trouble, as successful transplanting is very difficult, it is necessary to sow the following and other seeds outside in the positions where the plants are to flower: Poppy, Mignonette, Miss Jekyll's Love-in-a-Mist and Larkspurs. On the other hand, most hardy annuals, if the positions in the beds and borders are occupied when the time for sowing seeds arrives, may be sown in prepared seed-beds outside and transplanted later into their permanent positions. Sowing in temporary positions is more convenient in straight, shallow drills, otherwise the sowing may be broadcast, *i.e.*, thinly all over the surface, or, as illustrated, in short lines, which are easier to thin out. Seeds sown outside require just a little more covering with fine soil than those sown in boxes.

Pricking Out or Transplanting Seedlings.

There is work of this kind to do both in boxes under glass and outside. Antirrhinums, Hollyhocks, Pansies, annual Carnations, Delphiniums, Tobacco Plants and other seeds sown in heat under glass in February and early March are ready to prick off. Here, again, the shallow boxes recommended for seed-sowing can be utilised. Each of these with the seedlings pricked off as illustrated will hold from thirty-five to forty small plants. Outside in the beds and borders there are the autumn-sown annuals to thin and transplant. Larkspurs, Poppies, Pot Marigolds and Collinsias may be

mentioned. The illustration below depicts a group of such just ready for attention. As soon as transplanting is done, water the seedlings, unless it is raining. In thinning do not be too drastic at first. It is often better to remove half the first time, and then go over the beds again a fortnight later.

O. A.

DIVIDING PERENNIAL PHLOXES.

WHERE it is intended to divide these Phloxes or make a new plantation, this is perhaps the best time of the year for that work. One hears numerous complaints about Phloxes not doing well, or that they cannot be grown in this place or that. Perhaps in the majority of cases it is not so much the climate that is at fault as the position they occupy in the garden. If they are planted in a border where they will be partially shaded from the fierce rays of the sun and given copious supplies of water during the summer, there need be no fear of failure. Early in April give a good mulching of farm-yard manure, and let it remain on the surface all the season. Where extra fine spikes are required, the shoots may be reduced to three or four

3.—ANNUAL LARKSPURS SOWN IN ROWS IN AN OUTDOOR BORDER. THE SEEDLINGS ARE NOW READY FOR THINNING.

on a plant, but for ordinary decorative purposes this will not be necessary. Cuttings taken off now and rooted in a cold frame will provide a nice show of bloom in the late autumn.

THE HERBACEOUS BORDER.

WHERE planting was not done in the autumn, this work may now be accomplished; indeed, for the more delicate sorts spring planting is preferred. Many of the stronger-growing subjects, such as Senecio, Helianthus and Rudbeckia, will require to be reduced, leaving strong growths from the outside of the group. The border should now be top-dressed with some good turf, manure from spent Mushroom-beds, and a good sprinkling of bone-meal. The utmost care must be exercised in pointing it over, more particularly where bulbs are grown

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Strawberries in Pots.—The ripening of these fruits has been delayed by sunless weather in March, but with lengthening days there should be no difficulty now in keeping up a daily supply. Keep the plants well exposed to the light and examine the pots several times daily. Give frequent supplies of liquid manure, for it is now almost impossible to give them too much water, especially if the pots are fully exposed to the light and air.

Early Peach-House.—The fruits in this house will now have finished stoning and commenced their second swelling. At this stage the night temperature may be raised to 65° without danger, rising to 75° by day with sun-heat. Syringe the foliage twice daily, and shut the ventilators early in the afternoon to secure all possible benefit from sun-heat. If the borders are properly drained, liberal supplies of water should be given, and a dusting of artificial manure may be applied with advantage at alternate waterings.

Vines.—In midseason vineries disbudding will now require careful attention, and should be accomplished while the shoots are in a young state, selecting those with the most promising bunch, at the same time having due regard to the length of the spurs. Admit air with caution, and shut the ventilators as early in the afternoon as is consistent with safety. As time advances and the Vines are growing freely, the shoots should be carefully stopped at the first or second eye beyond the bunch, according to the space available, and this should be done at intervals so that no serious check may take place.

Plants Under Glass.

Fuchsias.—Old plants of Fuchsias which have been dormant through the winter and are now making fresh growth should be pruned and repotted. It is necessary to remove as much of the old soil from the roots as possible, in order to avoid the use of larger pots at the commencement of the season. Young plants which were struck in the autumn or spring should be grown in a temperature of 60° with plenty of atmospheric moisture.

Chrysanthemums.—All late-struck plants should be potted into 6-inch pots as soon as possible. The compost should be moderately dry, so that it may be pressed tightly round the roots. The plants may afterwards be placed in a cold pit and kept close for a few days. Plants which were potted early must be freely ventilated, in order to keep them stocky. Keep a sharp look-out for fly, which must be destroyed at once if present on the plants. Cuttings may still be struck in a close, cool pit, and will make useful decorative plants for November and December; 6-inch pots are the most suitable for this purpose.

Celosia plumosa.—Seeds may now be sown in heat to provide a succession to those sown early in the year. The present sowing should produce well-developed plants for the conservatory during July and August. The early batch of plants may still be grown in a temperature of 60°.

The Flower Garden.

Sweet Peas.—Plants raised in pots will now be ready for planting in their flowering quarters. The ground is very cold and wet at present, but with lengthening days we may hope for better conditions shortly. The ground should be well forked over and a good sprinkling of fine bone-meal applied before the plants are put out. Great care should be taken that the roots are not injured when being transferred from the pots to the bed of soil. Allow ample space between the plants, as nothing will be gained by crowding, and, as soon as the planting is over, the sticks should be carefully placed in position. A sowing may now be made in the open to produce fresh flowers throughout the late summer and autumn.

Summer-Bedding Plants.—As soon as these are of sufficient size, they should be removed to cooler quarters. Lobelia and various dwarf subjects will benefit by being transplanted from the cutting-boxes into shallow frames; 4 inches of fine soil will be sufficient, and the plants should be placed as near the glass as possible. When

they have made good growth and are of suitable size, the lights may be removed during the day in order to harden them off.

Hollies.—The present is the best time to transplant Hollies. If dry weather prevails, the plants should be syringed several times daily and a good mulching provided. Protection from wind should be given, especially for specimen plants.

The Hardy Fruit Garden.

Apricots.—These trees will soon require disbudding, as this should be commenced as soon as the shoots are large enough to hold between the finger and thumb. Commence by removing the back and fore right shoots, then those which are badly placed; but do not remove too many at one time, as this may cause a check and numbers of the fruits will drop. If disbudding is carefully performed, it will reduce the need for hard pruning in the winter. Retain as many well-placed shoots near the base of the tree as possible, but avoid overcrowding. Very little thinning of the fruit should be practised until the stoning period is over, unless in cases where a heavy crop has set.

The Kitchen Garden.

Vegetable Marrows.—Seeds may now be sown in small pots and grown in a slightly heated pit. As soon as they have developed their first rough leaf, they may be potted into 6-inch pots and grown under glass until the time for planting arrives.

Salsify.—This vegetable may be sown about the middle of April in drills 18 inches apart, and thinned to 9 inches between the plants as soon as large enough to handle. Scorzonera may be sown now and treated in the same way.

Asparagus-Beds should be examined, and if the surface has been beaten down by heavy rain, the soil should be very lightly pricked up and a good dressing of agricultural salt applied. There should be no delay in sowing Asparagus seed, and the seedlings should be ready for planting in two years' time. Sow in shallow drills 18 inches apart, and thin the seedlings to 6 inches as soon as large enough to handle.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions that were raised in boxes may now be planted out; at least, any time from now till the end of the month. Of late years many private growers prefer sowing the bulk of their Onions in boxes in preference to sowing out of doors, and there is a good deal to be said for this practice where large bulbs are desired. It is generally admitted that transplanted Onions do not suffer so much from the ravages of the maggot as those sown outside. At the same time, where one has to have a supply of small Onions, it is necessary to sow in this way.

Lettuces.—Those that were sown under glass and transplanted into boxes may now be safely planted out on some warm border. It should be remembered that Lettuces require a good, rich soil to produce nice, crisp heads, so that if the ground has not received a liberal dressing of manure earlier in the season, a little short stable litter should be forked in before planting.

Broccoli.—Winter and spring Broccoli should now be sown, although many recommend sowing up till May. In our climate, however, I do not think this is advisable, as we generally find that the April sowing gives the best results. Prick out the seedlings in a prepared bed when large enough to handle, in a similar way to Cabbage, with this difference—that they should have more room between the plants. If one has not sturdy little plants to begin with, they will be sure to suffer during very severe weather.

Egg Plants.—Although not grown extensively for cooking purposes hitherto, I am told these make quite a delicious vegetable. As they are rather tender subjects, the seed should be sown in small pots indoors and the seedlings thinned out; indeed, they may be treated in the same way as Tomatoes. As, however, they are subject to attacks from red spider, see that they are not placed near

Vines or Peaches, otherwise they may cause a good deal of trouble.

Small Salads.—To provide a regular supply of these salads, a start should now be made with a small sowing outside. As the majority of these are surface-rooting plants, care must be taken to keep them well supplied with moisture at the roots.

The Flower Garden.

Linum Provinciale.—This lovely Flax is in habit quite distinct from any of the other varieties of these fine perennials. The stems are quite erect, and taller than *L. Lewisii*, which is inclined to droop. Curiously enough, however, I cannot find it in any of the hardy plant lists I have by me. With us it is certainly the most outstanding plant of its colour (pale blue) in our herbaceous collection. Anyone who should happen to come across it would do well to add it to their collection. It has also the additional merit of blooming almost throughout the season.

Repairing Paths.—Where this was not done earlier, no time should be lost in seeing to this very necessary work. During March the rainfall in some districts was abnormal, so that the drains and traps were severely tested in consequence. Where gravel is used on the paths, it would be advisable to have it passed through a riddle. This will rid it of soil, and assist in destroying weeds and moss. Some will say this is a big task. So it is, but it will pay if one can find time for it. The work, of course, must be done in fine weather.

Stocks and Asters.—The earliest of these will now be ready for pricking off, at least when they attain the third leaf. As soon as they obtain a hold of the soil, remove them to some cool and airy house, as they will not do well in a close atmosphere. There is, however, still time to make a sowing; and should one be favoured with a good autumn, it is just possible this late sowing will produce the finest plants.

Plants Under Glass.

Herbaceous Calceolarias.—As these useful and attractive greenhouse plants become well rooted in their flowering pots, artificial feeding should commence. Calceolarias do not seem to care much for chemicals; indeed, for the most part I would advise using liquid from the byre or stable, which will be found to be as good as any. In addition put a small bag of soot in the water tank; this will be found to be a grand fertiliser. As soon as the flower-spikes appear, they should be staked with neat little sticks, which, if skilfully done, will scarcely be visible. When the flowers begin to open, the house must be shaded on bright days, otherwise the plants are inclined to flag. Artificial feeding should be discontinued when they come into bloom.

Pruning the Myrtle.—Only in very favoured districts in the North can one risk growing this plant out of doors. In the conservatory it is inclined to get somewhat out of hand, and the present time will be suitable to prune back straggling shoots. An opportunity should be taken to give it a thorough cleansing; this is best done with a garden engine when the young growths are about three inches or four inches long. A few cuttings might be inserted in pots, and when rooted I find they make useful plants for furnishing the greenhouse.

Hippeastrums (Amaryllis).—No time should be lost in getting the main batch into heat. If it should be necessary to repot any of the larger bulbs, do so now, using some good loam and charcoal. In most cases, however, top-dressing will be all that is necessary. Plunge them in Cocoanut fibre, and water very sparingly until the flower-spikes appear.

Fruits Under Glass.

Mealy Bug on Vines.—Although the resting period is the proper time to rid the Vines of this dreadful pest, it is surprising how the insects persist in making their appearance even after we had thought we had got rid of them. Still, we must exercise patience and keep working away, and much can be done even now by going over the Vines from time to time with a small camel-hair brush dipped in methylated spirit and just touching the insects, which will at once destroy them.

BLUE AND RED HYACINTHS.

SOME INTERESTING FACTS.

THROUGH the kindness of Messrs. M. van Waveren and Sons of Hillegom I have enjoyed in my greenhouse last month and this a very considerable collection of single Hyacinths of various shades of blue, pink and red. A bulb of each variety was put into three different sized pots; otherwise in every other detail all were treated exactly alike. They were potted on the same day, placed in the same position to root, and brought at the same time to the greenhouse.

The Best Sized Pots.—My experience, which may be of interest and of some utility to others, is as follows. First, I was rather surprised to find how little difference the size of the pots made. Four-inch or 6-inch brought almost equally good spikes, and even in some extra deep ones, where there was considerably more root room, the difference was but slight. On the whole, I would advise 5-inch pots as being the best and most convenient for first-sized single bulbs. Four-inch pots are quite large enough for second-sized ones.

The Strongest Growers.—Secondly, although according to St. Simon, who published a famous monograph on the Hyacinth in 1668, red was probably the original colour of the flower, I can only say that I liked the red shades the least of all I grew, and that I found them to be decidedly the poorest doers. The strongest and the most pleasing were the pale blues and the pinks. These were without the smallest doubt by far the most popular among the visitors who saw the collection. Pale or light blue varieties have always, I fancy, been favourites, ever since, as I might say, there were Hyacinths. In 1703, in the "Dutch Gardiner" we find only blue ones mentioned (sic): "The Hyacinth, that is handsom must have a clear Porcelain or China Blew, or near a white Colour, great Nails standing round the stalk in a Pyramidal fashion, but running up more Taper-wise." Other shades and colours were in existence, but they were esteemed less choice. At the time of the Hyacinth mania (1733-34), according to a contemporary list of prices, whites must have been quite as popular and as much thought of as pale blues, although the one of highest value was a blue Non Plus Ultra, one bulb of which, with its natural offsets, changed hands at 1,600 guilders (about one hundred and thirty-three pounds). In the Hyacinth catalogue given by St. Simon (1668) blues predominate, both as doubles and singles. Whites come next, then red and rose, and then, a long way off them in numbers, come the single yellows. Hence this date must mark the first beginnings of this colour in the Hyacinth. But all this is of academic interest only. Nice as it is to know just a wee bit of a flower's history, a matter-of-fact public will be thinking, as their eyes run over these lines, of their next bulb order, and they will be wondering what, after all this superfluous steam, I am going to advise them to buy. So no more dipping into the past. Anon to the present.

The Blue Varieties.—Taking the blues first, and according my own special favourites the premier position, I would bracket together for the pale blues, Perle Brilliant, short, loose spike with beautiful large bells, with light blue exteriors and pale mauve insides; Grand Maître, tall

spike, of Dutch china blue; Competitor, late flowering, wide segments, a paler shade of the last; and Potgetier, a lovely pale silvery blue, drooping bells, the whole spike reminding me of a Spruce with snow on its branches. For the dark blues I must put Menelik, very dark, compact spike, each petal has an almost black stripe down its centre and is edged with very rich deep purple; and William III., loose spike, dark blue bells, as equal first. Both are excellent and of quite a different style and shade of colour. The former has a very glossy appearance, while the latter is distinguished by its light-looking spike and whitish eye.

In the Pinks two beauties are Lady Derby, superb shade of soft pink, with a slightly deeper line in the centre of each segment, late flowering, medium-sized spike; and General de Wet, a paler pink, long spike, bells not too crowded, each segment curls back, good doer. Then for a third I must go to Ornament Rose, very pale, waxy-looking bells, compact spike; or to Rose à Merveille, if a still paler shade is desired. This latter I would describe as a cream almost more than a pink, it is so pale. Four Hyacinths of deeper colouring that always seemed to catch my eye were Lord Macaulay, bright rose with paler centre, rather crowded spike, not over long; Queen Wilhelmina, one of my favourite loose spikes, pretty rose pink, curious hook on tip of each petal; Solfatare, cherry colour with whitish eye, spike short, flowers look rather as if they were on stilts—still, with all defects, a most pleasing shade; and King of the Scarlets, most distinct, back of petals vermilion, face rich bright crimson, tips of petals inclined to be green. I have forgotten Garibaldi, for it was long past its best when these notes were taken. On no account must I omit it, for it is a grand extra early of great lasting quality, and, as the lists say, of a glowing carmine.

So ends my selection. I know the varieties are not the ones that everyone would choose. I seem to be attracted to the mid-blues like Grand Maître, Count Andrassy, Competitor and the like, more than to the pale mauves like Czar Peter and Johan. When I go to the pales I like the blue tint in Potgetier, while the long spike of Electra is charming. In pinks my taste seems more normal, and perhaps most of those who have seen my flowers have chosen as I have done. Jacques, with its immense Sprucey-looking spike, is excellent. Of the varieties with pronounced stripes, which somehow always remind me of the Paradise sweets of my childhood, I think Queen Maria Sophia, a very early bloomer, and Fabiola, which is decidedly on the late side, the most pleasing.

JOSEPH JACOB.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment is desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PROTECTING SAXIFRAGA BURSERIANA (M. J.).—The plant itself is quite hardy, and would require no protection from that point of view. If, however, you wish to preserve its beauty at flowering-time, then a sheet of glass for protection would be best, raising it a few inches above the tuft. The glass should be large enough to cover the entire plant and to prevent the rain driving under to destroy the effect. A mulching of granite chips about the plant would also assist to the same end.

GROUPING LILIUM CANDIDUM AND ANCHUSA (M. M. K. C.).—Such a grouping by way of contrast would look very well, provided both could be had in flower together. If you are only now planting the Anchusa, it is hardly likely that a satisfactory flowering will follow this year, and both plants are better when established. If you employ the Delphinium and white Lupine in addition to the above, the former would have to figure as a front-row plant by reason of its dwarfness. If an edging is desirable, you could not have anything better than the white Pink Mrs. Sinkins, which would be in keeping with the scheme you have already in view.

ALPINES FROM SEEDS (E. H.).—Very few of those you name come absolutely true when raised from seeds. Aster alpinus, Aubrietias, Dianthus, Gentian, Saponaria and others all vary slightly. Happily for the gardener, for progress and for evolution that it is so. Some plants—the first two named are generally good instances—give a great variety of colours when raised from seeds. Some are the veriest weeds, others the finest gems, and the gardener, by discarding the former and propagating the latter, is left with vastly improved strains of each. Plants difficult to improve by cross-breeding are frequently endowed with the inherent attribute of great variability when raised from seeds, and in that way provide a wide range of colour.

TO GROW MOSS BETWEEN PAVEMENT STONES (Artist).—The best way to establish moss between pavement stones is to thoroughly soak the stones and interstices with water; then introduce patches of moss. Keep the moss damped over regularly for a period of several weeks, and in the event of hot, dry weather occurring, shade it lightly and damp the shading material several times a day. These patches will fruit later in the year, and the moss will gradually spread over the desired area. It is not possible to purchase spores to sow. There is no special chemical condition of the soil necessary for the establishment of moss, but it must be permanently moist—that is why moss increases so rapidly during the autumn and early winter.

PENTSTEMON AND ROSE (Burton).—Generally speaking, the hybrid Pentstemons, to which no doubt you are referring, flower more abundantly, though naturally somewhat later, on the cut-back plants. Those left alone flower earlier, but the spikes—and the flowers, usually—are less fine. This state of things is, however, modified by weather conditions, and the plants rarely behave exactly alike in two successive seasons. When cut back, it should be to within 2 inches of the ground, the operation taking place early in March. If the shoot of the Rose is well matured, it may be pruned back to 18 inches from the ground-level, or to any prominent eye or bud at about that point. Should the growth referred to be late made and sappy, good eyes or buds would be scarce at the height mentioned, and such pruning to a foot from the ground would only result in sappy growth again. On the other hand, a well-ripened shoot might be shortened to half its length, and, pegged near the ground, would give a moderately good flower from every prominent eye on the stem.

PLANTING ALPINES (K. H., Cheshire).—During the early spring months quite a large number of alpine may be divided and replanted with hope of success. Generally speaking, early April is a good time for the operation, while established examples may be planted from March to May inclusive. All seedling alpine should be transplanted or transferred to more permanent positions in the spring, the object being to afford the young plants a full season's growth ahead in which to make good specimens. The Dryas and Soldanella could be transplanted at any time; the Anemone seedlings at any moment

when they are on the move. Many alpine are easily raised from seeds, and if you have the necessary patience and convenience for dealing with such things, it would pay you a hundredfold. If you do not possess these essentials, you should buy plants. Seed should first be sown in boxes, pots or pans, and the seedlings pricked off before giving them their permanent positions. Some may be sown in frames, others in drills in the open. The address of Mrs. Lloyd Edwards is Bryn Oerog, near Llangollen, North Wales.

TRANSPLANTING GODETIAS (*Mrs. Walton*).—These do not transplant well, particularly when they have attained to any size. Far better results are obtained when the seeds are sown where required and early thinning resorted to. Both these and Clarkias may be transplanted in their earliest stages if the work is carefully done and the plants watered intelligently. If you desire a good display, it would be better to transplant them into pots when quite young, and from these to the flower-beds where required. The slugs might be disposed of by a dressing of some soil fumigant when the ground is vacant.

STONE DAMAGED BY FROST (*E. F. O.*).—We fear from your description that an unsuitable stone has been employed. Most types of stone harden by exposure, while certain others, no matter how placed, yield to the influences of weather and climate. If we are correct in our surmise, disintegration will continue, particularly in times of frost. A little of this is often advantageous, i.e., sympathetic to vegetable life; but if disintegration is continually going on, or present in large degree, we can only conclude, in the absence of fuller particulars or an examination on the spot, that the stone is itself of too soft a nature. We know of no chemical that will harden it.

TREES AND SHRUBS.

CREeping ARBUTUS (*V. P. V.*).—By *Creeping Arbutus* we presume that *Arctostaphylos Uva-ursi* is meant, or, perhaps, *A. alpina*. The former is the better trailer and has been called *Arbutus*. The most likely firm to apply to for plants is Messrs. James Smith and Sons, Darley Dale, near Matlock. If they do not stock the plant, it is likely that they could procure it.

HEATHER FOR EXAMINATION (*W. B.*).—There was nothing about the specimen of Heather sent for examination to enable us to determine the cause of death. It may be that some fungous disease has attacked the roots; or a root-eating grub, such as the larva of the cockchafer, may have been at work, but there was nothing to betoken the presence of either. Examine the ground and surrounding plants carefully for grubs or fungus mycelium.

TO PRUNE A BAY TREE (*Eglinton*).—The Bay tree may be pruned hard back about the middle of April. If the plant is in a tub and you can arrange to place it in a greenhouse with a close and moist atmosphere for a few weeks, keeping it well syringed two or three times a day, shoots will appear more freely than if the plant is left out of doors. If it is planted out, however, and the weather is dry, the production of new growth may be assisted by syringing two or three times a day.

TO PROPAGATE ERICA CARNEA (*G. K. M.*).—This Erica may be increased by any one of three methods—by seeds, by layers, or by cuttings. Seeds should be gathered when ripe and sown on the surface of pans or boxes made up of sandy peat. Drain the pans or boxes well, then make up to within an inch of the top with coarse compost, over this place half an inch of finely sifted compost pressed level and moderately firm. Sow the seeds thinly over the surface, water by soaking, and put in a shady place in a moist greenhouse. Cover with a sheet of glass and afterwards with paper. The seedlings will appear in about a fortnight. As they grow, gradually remove the glass, and when large enough to handle prick the seedlings off in a prepared bed of sandy peat in a cold frame. Layers may be put down at any time during spring or early summer. Place sandy peat beneath the branches, and weight the branches down by means of stones. They must be left for two years before being taken off as separate plants. Cuttings of young shoots may be made from 1 inch to 1½ inches in length during July and August, and be inserted in pots containing a compost of two parts peat and one part sand, made very firm. The pots must be placed under bell-glasses in a shaded and close frame. Cuttings of the same kind may also be rooted in sandy peat if placed under a handlight in a shady place out of doors. Plants raised from cuttings are usually the most satisfactory of all, but as the cuttings are so small they need very careful handling and must be inserted with great care. They root in from four to six weeks.

THE GREENHOUSE.

INJURY TO ASPIDISTRA (*Homo*).—It is impossible to say what has been damaging your *Aspidistra* from the specimens sent. It may be slugs, which hide in the soil during the day; but can it be through the scratching of cats?

PELARGONIUMS NOT DOING WELL (*Moon*).—The appearance of the foliage of the *Pelargonium* suggests that it has been growing under unfavourable conditions of moisture and temperature. There may also have been an attack of aphides, but the main damage is the result of too moist an atmosphere.

PHYLLOCACTUS NOT DOING WELL (*J. W. M.*).—These further specimens enable us to say there is a fungus allied to the "damping off" fungus growing in the brown part at the base of the stem, though the upper parts are free. No doubt the conditions have been too moist and close for it, and we recommend you to bake the soil before

you plant healthy cuttings in it, and take care that the drainage is ample and overwatering is strenuously avoided.

FEATHERY CHRYSANTHEMUMS (*S. L.*).—The plants make breaks and show crown-buds in just the same way as other sections; but both the varieties—namely, *Jitsujetui* and *Mrs. W. Butters*—do best when left to make natural breaks, and then produce natural shoots. If disbudded at the end of August, the resultant blooms will possess many petals, but short. Do not, therefore, disbud, but let the plants flower naturally; then the sprays will be fluffy and attractive.

GRUBS ON ADIANTUMS (*N. B.*).—The grubs are the larvæ of a weevil about three-eighths of an inch long and much the colour of the soil. They do great damage to roots of various greenhouse plants, and, when they mature, the beetles feed upon the foliage of Ferns and the like, and on shoots of Vine and even on foliage of fruit trees. They are troublesome pests to deal with, but as you are repotting the Ferns it would be best to pick all the larvæ out which are to be found in the pots. They may be killed by pouring a teaspoonful of carbon bisulphide into a hole made in the soil with a piece of stick, closing it again immediately. The weevils hatch in April or May, and when they are about, if the pots are shaken after dark (when the beetles feed) over a piece of paper or cloth, many may be captured and killed by dropping them in hot water or paraffin.

ABOUT CHRYSANTHEMUMS (*J. G.*).—Tobacco water may be used on the foliage as a preventive of the leaf-mining maggot. A tablespoonful to three quarts of water would be a strong enough dose. Quassia extract, used according to the directions given with it, would be better, and petroleum emulsion, violently stirred in water, is also good. A wineglassful to a gallon of water will do. If these mixtures—the last two referred to—are syringed on the leaves once a fortnight, they will prevent the fly laying eggs in the leaves. If the shoots of the plants are stopped, 2 inches being pinched off the end, the flowering of the plants will be delayed a fortnight or so, but the quality of the blooms will not be as good as those on plants not as severely stopped. The best way is to retard the plants and the development of the buds in the autumn. No; it would not be advisable to saturate the potting compost with liquid manure before use. Please send some Sweet Pea plants for inspection.

TREATMENT OF BORONIA MEGASTIGMA (*J. M. B.*).—When the plant has done flowering it should be cut back into a neat, compact shape. Then, if kept in the greenhouse, young shoots would soon be pushed out, and as soon as these are about half an inch in length the plant must be repotted. For this purpose the pot should be a size larger than the old one, quite clean and effectually drained. A suitable potting compost is good fibrous peat and sand. This must be pressed down very firmly, and care taken not to bury the ball of soil deeper than it was before. Seeds are occasionally to be obtained, and when this is the case, they afford a ready means of increase. At the same time, seedlings do not flower in a small state in the same profusion as plants raised from cuttings; hence this latter method is usually employed for their propagation. Cuttings are not at all easy to strike, the most successful method being to dibble them into well-drained pots filled with fine peat and sand, pressed down firmly, and covered with a bell-glass till rooted.

VARIOUS QUESTIONS (*G. A. W.*).—From what you say about your *Rose Maréchal Niel* we imagine that the soil in the bed has become sour. Possibly the bed is not well drained. It may be, however, that improper ventilation, resulting in mildew, is the cause. Should there appear to be signs of mildew, spray the leaves with Bordeaux mixture, which may be procured from a chemist. If the leaves continue to fall, remake the bed, taking care to drain it well at the time. The manure you propose using is quite suitable for a healthy plant, but if the soil is to blame, it will not assist your *Rose*. Perhaps a local expert could be induced to call and examine the condition of your bed. You may repot your *Deutzia* at once, using a compost of four parts good loam to one part each of leaf-mould, well-rotted manure and sand. After flowering, the old flowering shoots should be cut away. Your Ivy-leaved *Geraniums* may be expected to break again quite vigorously from the old wood. Cut the dead ends of the shoots away at once, then keep the plants syringed twice a day until new shoots appear. Your plant of *Plumbago capensis* may be repotted at once, using a compost of two parts fibrous loam to one part of leaf-mould or peat, with a little well-rotted manure and sand. If it has not been pruned, prune the branches back at once. Those formed last year may be removed to within a few buds of the base. It is impossible to say what the worms were which you discovered in your soil, neither can we say whether they are likely to be detrimental to plant growth or not. You cannot do better than cut your *Oleander* well back at once, then keep the branches well syringed until new shoots are formed. You may then repot it in soil similar to that recommended for the *Deutzia*.

ROSE GARDEN.

ROSES BY POST TO AMERICA (*U. S. A.*).—There is considerable difficulty in sending *Roses* to America, as one must obtain a permit from the Agricultural Department at Washington. You might apply to the Board of Agriculture, 4, Whitehall Place, London, W., or ask your nurseryman to get one through for you. Or, if you care to do so, write to some American firm of Rose-growers and ask them to post a plant on to your friend. Doubtless Messrs. H. Dreer and Co. of Philadelphia, Massachusetts, would do this for you.

ROSES INJURED BY PESTS (*Miss D.*).—From your description it looks as though the damage was caused by the leaf-cutter bee, or mason bee as it is called. This pest generally nests in hard gravel walks or in holes in old walls, and may be seen hovering over the *Roses* on a sunny morning. The only remedy is to watch for it and trace it to its nest, which, of course, should be destroyed. Or it may be the *Rose* slugworm caused the damage by eating the surface of the foliage, which, in time, would cause the holes. For this, spray the bushes with nicotine wash or Hellebore wash. You could spray now and continue at frequent intervals through the early summer.

FRUIT GARDEN.

INJURY TO PLUMS (*Reigate*).—Your *Plums* have no doubt been attacked by the leaf-curling aphid. These pests hatch out about the last week in March, and spraying should be done as soon as they can be discovered on the opening buds, using either one of the nicotine sprays or Quassia and soft soap.

FRUIT TREES ATTACKED BY SCAB (*Brockley*).—Your trees are attacked neither by mildew nor by canker, but by scab. The best thing you can do with them is to remove all the dead or dying wood, spurs and the like, and to spray the trees with Bordeaux mixture at half the strength used for spraying Potatoes, beginning just as the buds are ready to burst (but before they open), and repeating at intervals of about three weeks. Take care that the spraying is done when bright sun is not shining upon them. From what you say, we think your *Apple Cox's Orange* must be planted in a draughty place.

KITCHEN GARDEN.

CHINESE ARTICHOKEs (*Valetta*).—To grow these successfully the tubers should be planted at once, 3 inches deep, 6 inches apart and 12 inches from row to row. Choose a south or west aspect. These revel in a light sandy soil, to which plenty of well-decayed leaf-mould should be added. About twelve tubers usually make one good dish.

BROCCOLI DAMAGED BY A FUNGUS (*Isle of Wight*).—The spots on the leaves of the Broccoli are due to a fungus which attacks almost all varieties of the Cabbage tribe, and might be kept in check by spraying with a solution of an ounce of potassium sulphide in three gallons of water when the disease first makes its appearance. It seems too late to do any good now.

FRENCH BEANS (*Valetta*).—Unless proper methods are adopted, the crop would not be very satisfactory at this season of the year. A greenhouse temperature would hardly suit them, as these will require at least 55° to 65° of heat, varying with the outside temperature. The cause of your foliage looking yellow in all probability would be too low a temperature, and most likely the plants too wet at the root; leaf-soil would not be the cause. The pots should be well drained and a light, moderate compost used. The presence of red spider is due to the atmospheric conditions of the house being too dry. This pest cannot thrive in a moist temperature.

MISCELLANEOUS.

POTASH FOR TOMATOES (*W. P.*).—Potash may be applied to *Tomatoes* in the form of sulphate of potash, either by mixing with the soil or by dissolving in water at the rate of half an ounce to the gallon, and watering with it occasionally.

CREOSOTING A FENCE (*E. P.*).—Your neighbour has full right to creosote not only his own side of the fence in question, but your side as well; but he has no right to go upon your land to do so. In other words, if you object to your neighbour going upon your garden for the purpose of creosoting the fence, you must hand over the fence in order to creosote your side, as otherwise he would commit a trespass. Your neighbour would be quite justified in compelling you to remove the posts supporting the wires if same are attached to the fence. Small quantities of creosote touching the bark of a dormant tree would not be likely to do a great deal of harm to it, though it would be deadly to foliage. The danger lies mainly in the fumes affecting tender shoots, as they would be likely to do, and in the possibility of some of the creosote washing down to and affecting the roots. The latter is probably less likely than the former, but fumes would continue to be given off for some time in warm weather. There would be much less danger if the work were done in November than if it were done now.

THE VALUE OF SOOT (*Toxic*).—Perhaps the following information may be of value to you with regard to soot. Its chief manurial value lies in the nitrogen it contains. Soots from short chimneys are usually much richer in nitrogen than from tall ones with a very strong draught. Those from the latter are usually very poor in nitrogen, and contain a considerable amount of ash. Soot is best valued by the amount of nitrogen it contains, and its value varies from about twenty-four shillings to five pounds a ton—the lighter samples being the better. A good soot should give four bushels to the hundredweight and be worth about sixpence a bushel. There is practically no other manurial substance of value in the soot, but it has somewhat greater value in the garden than these figures show. It helps to darken soil, which renders it more absorbent of heat, and its carbon, no doubt, aids in removing toxic substances, just as charcoal does. We regret we cannot carry out analyses for our correspondents. Fellows of the Royal Horticultural Society may get them done at a reduced fee by Dr. A. J. Voelcker of 1, Tudor Street, E.C.

THE GARDEN.

No. 2213.—VOL. LXXVIII.

APRIL 18, 1914.

NOTES OF THE WEEK.

Early Strawberries.—Anyone having a number of plants not required for forcing can have an early supply of fruit outside by planting these in a trench such as one would plant Celery in. The trench should be 4 feet wide by 1 foot deep. In this plant three rows of Strawberries, and when they commence to grow, a few old lights may be placed over them, which will provide the necessary protection. Many fine dishes of excellent fruit we have seen gathered from plants treated in this way.

A Fine Strain of Clivia miniata.—There are at Kew flowering now in the Temperate House and House No. 4 some magnificent varieties of Clivia miniata. The flowers are remarkable for their size, some of the individual flowers being over four inches across, while there are as many as twenty blooms on a single truss or inflorescence. The flowers have broad, overlapping segments of bright orange hue, paling off to yellow at the base. Some of the flowers in shape and in the curvature of the anthers resemble those of the Amaryllis.

The Hoop-Petticoat Daffodil. Some of the diminutive Narcissi are really lovely in the rock garden, but it is doubtful if any of them are so beautifully adapted for associating with choice alpine as the Hoop-Petticoat Daffodil, botanically known as Narcissus Bulbocodium. The flowers of the species are bright yellow, but the variety citrinus, native of the Pyrenees, has sulphur-coloured flowers, which are even more pleasing. The bulbs should be allowed to establish themselves in a light soil and sunny position on the rock garden, as they do not, as a rule, all bloom the first year after planting.

Green Fly on Roses.—Complaints have reached us from several districts about aphides attacking the young shoots of Roses. On making investigations we find the trouble is a serious one, in some instances nearly all the young shoots being badly infested. Of course, the majority of these would be removed at pruning-time, and, let us hope, consigned to the flames. We draw attention to the pest now to put readers on their guard. Steps should be taken at once to spray all bushes wherever there is a possibility of insects being

present, but the insecticide should be used weaker than it would be later on when the foliage is harder.

Sowing Lawn Grass.—Those having lawn grass seed to sow will find the present as good a time as any; but, of course, much will depend on the state of the soil. It is essential that the surface should be got into a very fine state by repeated raking and rolling. As most of the seeds of the finer grasses are very light, the sowing must be done on a calm day, otherwise the seeds would be blown into patches, which is most objectionable. As sparrows and finches are particularly fond of grass seeds, it will be necessary to protect the

6-inch pots. Place a 4-foot stake in each pot and train up the leading shoot, rubbing out all side growths as they appear. Stop the plants at the top of the stake to induce them to form a head. Some time in July they should be plunged out of doors till the autumn. About next February they may be potted into 9-inch or 10-inch pots and brought on gradually. It is not advisable to pinch out the flowers at any stage of their growth; this gives the plants a check. Rather let them grow naturally.

Watering Recently Planted Trees.—Should the weather be hot and dry, all recently planted fruit trees should receive a good soaking. Indeed, if it were possible, one might use the hose for this purpose. This will not only supply moisture, but wash the fine soil among the roots. When this has been done, replace the mulching, and the possibilities are that the trees will not require another watering for some time.

Planting Border Carnations.—If these were potted in the autumn and have wintered in cold frames, no time should be lost in planting them in their permanent quarters. The soil for this purpose should be rich, with a fair quantity of sand among it, and if this was dug early in the year, so much the better, as nothing will be necessary now beyond breaking and levelling the surface. The plants should then be carefully removed from the pots and planted firmly in straight lines at equal distances apart. Frequent dust-

ings of soot may be given with advantage during the growing season.

The Common Dog's-Tooth Violet.—Erythronium Dens-canis is one of the most interesting of hardy plants flowering at the present time. Even when out of bloom it is attractive, the leaves being mottled with a brownish colour. There are a number of beautiful forms, from pure white to dark purple, while some have broader segments. A colony of these is of great interest, and it is surprising that this old-fashioned flower is not made more use of. A peaty soil, with some shade, suits it best, although it grows and flowers satisfactorily in the full sun.

NARCISSUS BULBOCODIUM CITRINUS, A CHARMING VARIETY OF THE HOOP-PETTICOAT DAFFODIL.

plat in some way. If this is not too large, herring-nets can be used. On larger patches black thread may be placed on small twigs run across the ground in various directions. Ordinary lawns should now be swept and rolled, and where the grass is growing freely a start should be made with the mower.

Standard Heliotropes for the Conservatory.—These make a splendid addition to our summer-flowering plants in the conservatory. To those who have not gone in for this style of growing Heliotropes, the present is a very good time to make a start. Select some strong plants that have been grown in pots, and pot on, say, into

CORRESPONDENCE.

(The Editor is not responsible for the opinion expressed by correspondents.)

New Zealand Flax (*Phormium tenax*).—The cultural directions for this valuable plant given in THE GARDEN of April 4, page 176, seem to me somewhat misleading. It is true that it will grow well in "good, loamy soil," but that is by no means essential to its vigour. In its native country, I believe, its natural habitat is on land subject to winter inundation, and on sandy and shingly river banks. In the South-West of Scotland, where it ripens immense quantities of seed, it flourishes rampantly in swampy ground and peaty moorland, where few choice things would survive. The cultivation of it on a commercial scale has been undertaken in that region for the production of fibre of a superior quality.—HERBERT MAXWELL, *Monreith.*

Acacia dealbata.—Reading the correspondence on this subject on page 155, issue March 28, I thought a few words on this beautiful tree from this part would be interesting to readers. We have here in the gardens three large trees; the largest is about 4 feet in girth (6 feet from the ground), 35 feet high and 20 feet through. Two are somewhat sheltered from the north by two Eucalyptus trees, but the best specimen is not sheltered so much. These trees flower about January, that is, following a dry summer. I have known all the flower-buds destroyed on the north side with 6° of frost, while the south side of the tree has bloomed freely. I gathered some beautiful sprays this year. But, apart from its flowers, its silvery grey foliage is quite a feature in itself, being so finely divided and graceful in appearance.—J. J. GRIBBLE, *Penlee, Penzance.*

The Fifty Best Alpines.—Having decided to add a small extension to my rockery, I turned up THE GARDEN for last year's March and April in order to consult the four lists of the fifty best alpines then given, respectively by Mr. S. Arnott, Mr. Reginald Farrer, Mr. William Little and Mr. G. F. Hyland. Each list gives the names and cultural directions of fifty alpines which in the author's opinion are those best suited for a small garden. On examining the lists I find that they comprise 130 different plants—on the face of it a little bewildering; but, on going more closely into the matter, I find that, curiously enough, the names of exactly fifty plants recur in two or more lists. As it occurred to me that those of your readers who, like myself, value the opinion of others might wish to know the names of these fifty plants without being put to the trouble of finding them out for themselves, I enclose details. For cultural directions I must refer readers to the original lists given on pages 115, 151, 187 and 211 of THE GARDEN for 1913. In all four lists appear *Arenaria montana*, *Primula marginata* and *Saxifraga burseriana*. In three lists appear *Androsace lanuginosa*, *Aubrietia* Dr. Mules, *Dianthus alpinus*, *Gentiana acaulis*, *Hepatica angulosa*, *Hypericum reptans*, *Lithospermum prostratum*, *Oxalis enneaphylla*, *Phlox subulata* Nelsonii, *Primula nivalis*, *Saxifraga lingulata* lantoscana, *S. Wallacei*, *Silene Schafta* and *Veronica rupestre*. In two lists appear *Anemone sylvestris*, *Anthemis Aizoon*, *Aquilegia*

glandulosa, *Arenaria balearica*, *Arnebia echioides*, *Aster alpinus*, *Aubrietia Moerheimii*, *Campanula* G. F. Wilson, *C. muralis*, *C. portenschlagiana* major, *Dianthus neglectus*, *Dryas octopetala*, *Erinus alpinus*, *Geranium argenteum*, *G. lancastriense*, *Gypsophila prostrata*, *Haberlea rhodopensis*, *Hutchinsia alpina*, *Iberis sempervirens* Little Gem, *Mertensia primuloides*, *Myosotis rupicola*, *Onosma tauricum*, *Papaver alpinum*, *Phlox canadensis* Laphamii, *Primula clusiana*, *Ramondia Nataliae*, *R. pyrenaica*, *Saponaria ocymoides* splendens, *Saxifraga pyramidalis*, *Sempervivum arachnoideum*, *Silene alpestris*, *Tunica Saxifraga* and *Viola gracilis*.—J. M. STRUOWMAN, *Marlborough Cottage, Sofievej-Hellerup.*

The Kew Flagstaff.—It may interest you to know that the Kew flagstaff was cut within a mile of where this is written, and that a special port had to be cut in the ship in order to allow

RHODODENDRON INTRICATUM, A DWARF SPECIES FROM CHINA. THE FLOWERS ARE LAVENDER BLUE.

it to be got in. I believe a few feet had to be cut off the spar in order to get it into the ship. There is a movement on to send another and bigger spar to replace it. It will probably be 200 feet long if it can be shipped. The necessary trees are here. I noticed a few weeks ago a note in THE GARDEN about flowers visited by humming-birds. We get lots of them here in the summer, and they visit every kind of flower. I have a *Lychnis chalcidonica* just outside my dining-room window which they are very fond of, and have to stand on their heads to get at the middle flowers. They are also very fond of Carnations, Delphiniums, Columbines and Fuchsias. It is very pretty to see them hover motionless (except for their wings, which go too fast to see) in the air outside the window "sitting on nothing," as the children put it.—C. T. HILTON, *Third Avenue, Port Alberni, British Columbia.*

Stone Fruits in Scotland.—The Rev. David R. Williamson writes us as follows from Kirkcaldie Manse, Wigtownshire, on April 3rd: "Owing doubtless chiefly to the mildness of the present spring and the heat of last summer, there is every appearance of an abundant blossom on the stone fruit trees in South-Western Scotland this year. The extremely beautiful and effective *Prunus Pissardii* (the Persian Plum) has been for the last fortnight in luxuriant bloom in the centre of my garden. It has been closely followed by the Almond, whose pale pink flowers are just beginning to expand. Exceedingly promising, from a floral point of view, are such fine Plums as the Victoria, The Czar, Early Rivers' and Denniston's Superb Green Gage; also such varieties of the Cherry as Black Eagle, May Duke, Early Rivers' and Morello, which would be worthy of cultivation if only for their marvellous flowers."

A New Rhododendron for the Rock Garden (*R. intricatum*).—During the last ten to fifteen years our gardens have been enriched with many new species of *Rhododendron* from China. Mr. E. H. Wilson's introductions alone exceed fifty species and varieties, many of which so far have not flowered in this country. Among those which have bloomed, none has proved a greater acquisition to our gardens than *R. intricatum*, the subject of the illustration on this page. For the rockery and alpine garden it is an ideal plant. Mr. Wilson, in his notes on China, describes *R. intricatum* as one of the moorland species, growing 2 feet to 3 feet in height. Being a comparatively slow-growing plant with us, the compact little bushes are still less than a foot in height, though nearly seven years old from cuttings. An evergreen species, the small, oval leaves are a quarter of an inch to a third of an inch long, densely clothed on both surfaces with small, peltate scales, dark green above and a brownish white hue beneath. The dainty lavender blue flowers, each about half an inch across, are borne in clusters of three to five, and are very freely produced. At a little distance away, one of the plants suggests a bunch of Violets. The fact that there are several dwarf species of *Rhododendron* in China allied to *R. intricatum* has, unfortunately, led to some confusion in the names. The subject of this note, when first exhibited by Messrs. James Veitch at the meeting of the Royal Horticultural

Society on April 2, 1907, received a first-class certificate as *R. nigro-punctatum*. It differs from that species, however, in having the flowers in clusters, those of *R. nigro-punctatum* being solitary. A third closely allied species, also with lavender blue flowers, named *R. fastigiatum*, has been recently introduced from China by Mr. G. Forrest. This is readily distinguished from *R. intricatum*, as it has prominent exserted anthers, those of *R. intricatum* being shorter than the corolla. The best means of propagation is by cuttings of partially mature shoots inserted in pots of sandy peat during late summer. For preference plunge the pots in a propagating-pit with a little bottom-heat. The plants illustrated are growing in a well-drained bed of sandy loam, peat and leaf-mould. The flowering season is March and early April. The accompanying photograph was taken on April 4.—A. O.

Corydalis cheilanthifolia.—This pretty plant has given me much pleasure ever since I had it some years ago from the garden of my greatly regretted friend, the late Dr. A. R. Wallace. The deep green, Fern-like foliage is always a joy to see when there is but little well-developed plant life early in March, with the fresh interest of the bright yellow bloom that comes a week or two later. It comes up freely from self-sown seed, but this year, to my great pleasure, it has appeared on both faces of a high wall at a height of from 7 feet to 10 feet above the ground. The wall is of the local sandstone, built less than thirty years ago. How the seed got up to that height on both sides of the wall, and how it can have found lodgment and the little plants nutriment, is a complete and delightful puzzle. The plants in the wall are naturally smaller in foliage, and the proportion of flower to leaf greater, than where they grow on the level or on ordinary rockwork.—G. JEKYLL.

Aster Disease.—I notice a very interesting article on this subject in *THE GARDEN* of March 21 issue, but, while admitting that the course advised there may be a feasible one under certain circumstances, I cannot say that gardeners will derive much benefit or consolation from it. I have carried out some experiments in connection with this tantalising and disastrous disease, and I find that a 2 per cent. to 3 per cent. solution of formalin invariably secures immunity. The method of using this liquid is very simple; the soil of the border is ridged up, then sprayed liberally with the liquid, and the ridges are levelled down roughly so that the fumes may be conserved. The border, however, must be vacant for at least three weeks before plants are placed in the soil, and, if possible, this period should be increased for a week or two. We have used the same solution for the composts in the seed-pan, and for the boxes of soil into which the plants were pricked off. To prevent introduction of the disease with new seeds, we now steep all for fifteen minutes in a very weak solution of formalin, one teaspoonful of the commercial liquid (40 per cent.) in one gallon of soft water, and no trouble is ever experienced. Experimenting with soils and manures, we also find that fresh organic matter or heavy dressings of nitrogenous manure encourage the development of the fungus, and my advice to readers is to plant Asters in soil which is "in good heart," *i.e.*, which is rich, but has not been recently manured.—H. H. A.

Bulbs for Spring Planting Outside.—While no one will gainsay Mr. Arnott's dictum on page 139, issue March 14, that many bulbous-rooted subjects "require to be lifted in late autumn and stored until spring," few, I think, will share his views that the middle of March is a "good time" to plant the Belladonna Lilies, and, among others, the hardiest of the *Alstrœmerias*. By the recommended planting-time the first named, given the shelter of a greenhouse wall or south wall, have in the ordinary course made leaf growth from 6 inches to 12 inches above the ground, and the cultivator cannot keep such a bulb in the dry state for months with impunity. Moreover, as is distinctly pointed out at page 139, the Belladonna Lily is quite hardy in the positions indicated; hence there would appear no legitimate reason for deferring the planting till so late a date. In the case of the *Alstrœmerias*, the growth would be very near the surface in March, while long-established patches might even be well through the soil;

hence one does not see the gain to be derived. On the contrary, assuming that dry bulbs or tubers of those named are employed, there will be an unmistakable loss of all that is of benefit to the future plant—root-fibre and leaf production, for example, which, combined and developed in due season, are essential to bulb growth. With certain plants—the tuberous *Anemones* and *Ranunculi*—little or no harm follows this deferred planting; hence for the sake of expediency, and with a desire to extend a season of flowering more particularly, it is worth pursuing.—E. H. JENKINS.

Lime in the Garden.—In reply to "J. D.," page 143, column 1, taking the last paragraph first, "J. D." would be far better advised to use soot in preference to lime for his lawns. Used now at the rate of 20 bushels (costing 10s.) to 1,400 square yards, he would be agreeably surprised in a fortnight's time. This will destroy moss and many other weeds, besides imparting a beautiful colour to his lawns. With regard to the use of lime for Potatoes, after twelve years' experience I unhesitatingly say that it is one of the finest things that can be used for the prevention of scab. I mean the scab caused by insects, not black scab, which is of fungoid origin. I have used quicklime, covering both the shoot and Potato, without the slightest injury. As to quality, I quote the words of a well-known Scottish authority, who once said to me, "I wouldn't have believed that such Potatoes could be grown out of Scotland."—S. G. SMALLRIDGE, *The Gardens, Battledene, Newbury*.

— With regard to the use of lime for Potatoes, doubtlessly a good many growers are influenced by the fact that in the leaflet issued by the Board of Agriculture on the subject, the application of lime is said to be one of the causes of scab, *i.e.*, the ordinary Potato scab, not black scab. This is an error. Scab is most likely to occur in soils in which the skins of the swelling Potatoes are injured or punctured by stones, grit or similar unyielding bodies in the soil. On land dressed with night soil containing ashes, scab is almost sure to occur, and a belief widely prevalent, that land under Potatoes for the first time is likely to produce a scabby crop, arises from the fact that the thorough working necessary for Potato culture has previously not been necessary, and consequently the land has not such a fine tilth and the tubers are more likely to be abraded in the rough soil. The experiment on which the Board of Agriculture based their theory was carried out in the following manner: Lime was taken on to the land previous to use, and allowed to lie exposed to heavy rains until not only was it slaked, but reduced to a pasty mass—to all intents, mortar. This was applied to part of the field, and the results were what might be expected. The lime set in lumps, and scab was more prevalent in that plot than in the unlimed portion. Freshly slaked lime, applied in spring in powdered form up to three tons per acre, will not be detrimental to any Potato crop, but, besides its chemical action on the manure, will prove a valuable fungicide as well.—F. M. S., *East Yorks*.

FORTHCOMING EVENTS.

April 21.—Royal Horticultural Society's Exhibition and National Auricula and Primula Society's Combined Show at Vincent Square, Westminster. Lincolnshire Daffodil Show.

April 23.—National Rose Society's Spring Show at the Royal Horticultural Society's Hall. Midland Daffodil Show at Birmingham (two days)

THE ENEMIES OF THE NARCISSUS.

NOT very long ago it was written of the Narcissus that it had "but one insect and one disease." Alas! this dictum cannot be accepted at the present time, and it behoves those who grow this beautiful flower—and who does not?—to at once realise the many dangers which beset the path of the cultivator.

The Lesser Narcissus Fly.—The enemies of the Narcissus are many, and the cry, unfortunately, is "still they come." The latest to claim attention is the lesser Narcissus fly (*Eumerus lunulatus*), which would appear to at least rival its greater brother, the Merodon equestris, in its capacity for destruction. The two flies are closely allied in entomological classification, and both eat out the interior of the bulb, resulting, in almost every case, in its complete destruction. In one way the *Eumerus lunulatus* may be less to be dreaded than the larger Narcissus fly, for it does not appear to do what the latter is accredited with doing, namely, lay its eggs, variously stated at sixty or a hundred per fly, each in a separate bulb, but, so far as can be at present ascertained, very many, if, indeed, not all, of its eggs in the one bulb which it first attacks.

But it makes up in thoroughness for what it may lack in other respects, as the following will show: In two bulbs of N. Bernardino just raised were found, respectively, thirty-two and eighty grubs, and in a single bulb of N. Glory of Noordwijk over a hundred; in fact, the bulbs so raised were simply sacks of grubs closely packed. What this would have meant had the grubs been allowed to pass into the pupal state, and issue therefrom later as flies to propagate their species, presents to the imagination a truly appalling picture. Of course, some bulbs raised contained but few larvæ; but, up to the time of writing, some 2,000 have been destroyed, and the process of examination is not yet quite ended. With what serious quickness this pest may increase is shown by the fact that when, two seasons ago, I lifted and replanted my special Narcissus borders, I had none of it. Probably in that year (1912) newly purchased bulbs brought with them the larvæ, which employed their time in the following year for the results of 1914. Very little, if anything, has been known about this fly, so far as its attacks on Narcissi are concerned, although it has appeared in places in the Iris. During the last year only does it appear to have come under observation as an enemy of the Narcissus, when it was detected in the South-West Counties. Doubtless by this time it has made its home in many Narcissus gardens elsewhere, and it behoves everyone interested in the matter to make immediate search, if only to achieve the satisfactory result of finding that the enemy does not exist.

The fly is small, about the size of the common house-fly, so that attempts to catch it with a net would be useless. Like the Merodon equestris, the *Eumerus lunulatus* appears to be a "sunshine fly," for in no case have I found Narcissi growing under the shade of trees, whether planted in grass or otherwise, attacked. The grub is somewhat similar to that of the Merodon equestris, but is rather darker in colour, and is smaller, not exceeding five-sixteenth of an inch. In gardens in which the grubs can now be found, there does not appear to be any alternative to the plan which I am now

pursuing, namely, to have every blank space in a row carefully searched for the remnants of the missing bulb, and also to have every bulb showing distinctly unhealthy foliage lifted for examination. By this means the pest must be so seriously checked that the control of another season may lead to its practical extermination.

Fool's Cray. CHARLES E. SHEA.
(To be continued.)

**PEAT "ROCK" GARDENS.
AN INTERESTING EXPERIMENT.**

SO many people have asked me to give them the results of my experiments with what they are pleased to term my "peatworks," that I now, after having given the experiment a fair trial, set down the history of experiments and their results for the benefit of those who, like myself, are in a peat country or within reach of it.

When I first started cultivating alpiners, I proceeded in the orthodox manner, and duly built rockwork and added moraines and other features; but as my collection of plants increased, I found it difficult to obtain suitable stone without expensive cartage, and I was driven to search for substitutes. My soul abhorred the idea of concrete slabs, and one day, as an experiment, I inserted, in the place of a stone which I had removed, a slab of peat (cut from the top spit of a bog), with the happiest results. It retained the soil in its place, and the plants behind it took kindly to it, and eventually rooted into it. Next year, to the stone problem was added the soil problem. My gardener strongly objected to the constant removal of the best of his kitchen garden soil for the nourishment of my alpiners, and I ventured upon a further experiment—I made a "rockwork" entirely of peat, using large blocks—cut from the top spit of the bog—instead of stones, and filling up the pockets, some with loose peat, others with peat and sand, peat and loam, and peat and leaf-mould.

My friends were critical and sceptical. I was told that even if the plants survived, which was more than doubtful, it was quite certain that my peatwork would subside before the winter rains and frosts had passed away. But I am glad to say that these gloomy prognostications have not been fulfilled; the plants have thriven, and, after three winters' rain (our rainfall is somewhere under 40 inches), the peatwork has sunk very little, even less, I fancy, than some of the loam and stone banks, and I am more than pleased with it. Encouraged by this success, I made last year two similar, but larger, peatworks, and I hear that some of my friends are now following my example.

In order to arrest, if possible, the storm of indignation that this innovation might raise among the orthodox rock gardeners, let me say at once that I do not for a moment suggest that peat should become the universal material for "rockwork" construction; but for those—and they are very many—who, like myself, are within reach of a peat-producing district, it has several advantages. It is cheap to buy, easy to work, makes a splendid background for plants, keeps remarkably free from weeds, and, as I will relate, has proved an excellent material for growing alpiners in, and I think I may fairly claim from my experience that, at any rate, it is a very useful alternative to soil and stones. I will first give

various reasons, had to be built up against a high wall (some 10 feet high). I first banked up against the wall rubbish drawn from the garden—turves, rubble, &c.—and placed about eighteen inches of rough drainage stones on top. I then covered this pile with loose peat at least 2 feet deep, stamping it down firmly as it was shovelled up. This stamping is important; it prevents undue "sinking." I then found I had a bank of peat up against the wall some 8 feet to 9 feet high and sloping fairly abruptly from the wall to the ground-level (the wall faces south-east). The north-east side of this heap was then faced with large clods of peat, making it into abrupt cliffs or terraces with occasional bays and pockets, using the clods of peat exactly as if they were blocks of stone, and packing the spaces and crevices with loose peat. This cliff face extends to the end of the loose peat heap, and then projects to the east, about fifteen feet, like a long "nose." This nose is sheer on both sides, and is only some 3 feet thick at the top. The loose peat on the south-west side of this cliff was shovelled up against the cliff until it was level with the top of the cliff, and the loose heap was then contained by the wall on one side and the cliff on another. The heap was finally gradually sloped down on the other sides to the ground-level by the insertion of retaining blocks of peat here and there, forming descending terraces. The pockets and slopes were then levelled up with loose peat, or peat plus the other ingredients mentioned, and I proceeded to plant.

Now as to the plants, my idea being only to thoroughly test peat as a soil substitute for alpiners, there are plants of all sorts and sizes upon this peatwork, placed indiscriminately, with very little regard to effect. It needed some courage, in view of my friends' prognostications, to entrust one's treasures to the experiment; but I hardened my heart, and as far as was possible placed specimens of everything I had upon it.

Let us walk round the peatwork, noting the plants as we go. We start at the north-east side. Here the peat cliffs are nearly ten feet high and fairly abrupt. High up, the heights are crowded with Maples and Azaleas. A little lower on the face and from the chinks sprout

▲ CATKIN-BEARING SPRAY OF ALNUS OREGONA, THE MOST BEAUTIFUL OF ALL THE ALDERS HARDY IN THIS COUNTRY.

some idea of the form and construction of the original peatwork, and will then give a list of some of the plants growing upon it.

My rock garden has no pretensions to architectural beauty. I started with a small piece, and as the necessity for further space arose I built all round it. If I could pull it all down and start afresh, no doubt I should evolve something very different. The original peatwork, for

Hepaticas, Arenaria montana, Myosotis Welwitschei, M. pyrenaica, M. pygmaea, and Mossy Saxifrages everywhere. Lower down, in pockets of peat, sand and leaf-mould, Saxifraga mutata, S. Lyallii, S. mertensiana, S. Fortunei, S. brunoni-ana, and some dwarf Gaultherias. Saxifraga aspera and Boykinia occidentalis hang over the edge. Then Shortia galacifolia, Viola septentrionalis, Sanguinaria canadense, Jeffersonia

diphylla, *Viola glabella*, *Erythronium*, *Ourisia coccinea*, *O. macrophylla*, *Orobis cyaneus*, *Houstonia serpyllifolia*, *Wahlenbergia saxicola*, *W. gracilis*, *Goodyera Menziesii*, *Campanula pulla*, *C. Stansfieldii*, *Castilleja acuminata*, *Polygalas*, *Ramondias* and *Haberleas*; and all over the cliffs *Primula capitata* and *P. cockburniana*, and others, such as *P. Unique* and *P. angustidens* at the base.

Coming round the east and south-east sides of the "nose," we see *Oxalis adenophylla*, *O. enneaphylla*, *Myosotis rupicola*, *M. antarctica*, *Lithospermum prostratum*, *L. intermedium*, *L. Zollingieri*, *L. rosmarinifolium*, *L. Froelichii*, *Pellaea densa*, *Campanula muralis*, *C. garganica*, *Potentilla ambigua* and *P. Tonguei*. Then upon the south and south-west slopes and pockets Mossy Saxifrages at foot, *Viola gracilis*, *V. bosniaca*, *Saxifraga integrifolia*, *S. erioblasta*, *S. reflexa*, *Iris*, *Campanula pulloides*, *Oenotheras*, *Nierembergia rivularis*, *N. frutescens*, *Azaleas*, *Aquilegias*, *Gentians*, *Anemone blanda*, *A. multifida*, *Veronicas*, *Phloxes*, *Convolvulus althæoides*, *Daphne Cneorum*, *Codonopsis ovata*, *Tulipa kaufmanniana*, *Arnebia echioides*, *Mertensias* and many others.

On the newer portions of the peatworks are others—too numerous to mention here—on trial, some of which it is as yet too early to speak of with any authority. But my experience so far leads me to believe that there are comparatively few plants that will not succeed in peat, and some—not necessarily "lime haters"—do better in it with me than in any other soil. I have hitherto always lost *Nierembergia frutescens* in loam, and it has thriven and passed through three winters in peat. *Gentiana verna* and *Codonopsis ovata* I have never had so fine in loam. I must confess that I have not as yet tried the *Kabschia Saxifrages* or such inveterate heat-lovers as *Acantholimon*, but practically everything else in my collection is now in peat on trial, and the only failures I can chronicle are *Gentiana acaulis*, which exists, but turns yellow, and *Sphæralcea munroana*, which is a heat-lover and dies in the winter wherever I put it. I will try some of the *Onosmas* and *Æthionemas* in a pocket strongly diluted with sand just for the sake of the experiment, but we get hardly sufficient winter sun for them in the moraine, so I am not sanguine of success. But all alpine which are not inveterate drought-lovers I shall plant in peat with confidence.

I confess that I am surprised at these results. I had slight hopes that difficult and delicate plants would survive. It may be that peat, though moist, does not clog the roots in winter and retains its moisture in the summer, and so assists the plants growing in it in the same manner as the stone chips do in a moraine. Anyhow, as far as this place is concerned, the experiment has proved more than satisfactory, and if any of your readers care to try a similar experiment, I should be happy to assist them in any way I could. I note in M. Correvo's latest work that he is trying difficult plants in peat beds sunk in concrete tanks with artificial irrigation. In our damp climate such an arrangement is, of course, unnecessary. The list of plants I have given is far from complete; but I would, of course, give a complete list of those tried and on trial if it were so desired.

MURRAY HORNIBROOK.

Knapton, Abbey Leda, Ireland.

SOME UNCOMMON ALDERS

THE Alders belong to the widely distributed genus *Alnus*, comprising deciduous trees and shrubs, natives of Europe, America, North Africa and Asia. There are about twenty-five or twenty-six species, but probably less than twenty of these are in cultivation. In addition to these there are fully as many named varieties, principally of the two common species, *Alnus glutinosa* and *A. incana*. There are also two hybrids, *A. elliptica* (*cordifolia* × *glutinosa*) and *A. Spæthii*. With one or two exceptions, notably *A. maritima* and *A. nitida*, the Alders flower early in the year, either in advance of the leaves or as they develop. The trees, laden with the pendent male catkins, brighten up the landscape, heralding the approach of warmer weather. These, with the female flowers in close proximity, are borne in clusters at the ends of the thin terminal and lateral shoots.

Our common Alder, *A. glutinosa*, is a familiar and attractive tree, growing generally in wet

the species. They are usually borne in pairs, occasionally singly, rarely in clusters of three together, greenish yellow in colour. No other Alder has quite the stiff, straight habit noticeable in *A. firma*. Two new *Alnuses*, *A. cremastogyne* and *A. lanata*, are of recent introduction from China. Mr. E. H. Wilson describes the former as a tall, slender tree 80 feet to 100 feet in height. *A. lanata* is distinguished by the woolly character of the young shoots and under sides of the leaves. Two other attractive Asiatic Alders are *A. nitida*, a native of the Western Temperate Himalayas, quite hardy in this country, and *A. japonica*, a Japanese species.

Several varieties of the common Alder have distinctly ornamental leaves, the best being *A. glutinosa imperialis* (*asplenifolia*). In winter the reddish bark of the young twigs is distinctly pleasing in *A. incisa ramulis coccineis*, the tree being still more beautiful in January and February, when the male catkins mature.

The best means of propagating the Alders is from seeds, which, as a rule, are freely produced on the exotic as well as the native species in this

SPRAY OF A JAPANESE ALDER (*ALNUS FIRMA*). THE CATKINS ARE THICK AND RIGID.

and swampy places. Besides differing considerably in foliage in the summer, the male catkins vary greatly in size and other respects on the different species. Several of the exotic species surpass our native ones in this respect; in fact, *A. oregona*, from Western North America, a spray of which is illustrated, is one of, if not the, most beautiful of all the catkin-bearing trees cultivated in this country. At their best during the month of March, the male catkins are 5 inches to 6 inches long, in clusters of three to five, at the ends of the thin, twiggy growths of the previous season. Words cannot adequately describe their beautiful colouring and markings, a combination of red, orange, yellow and green of Oriental beauty. The weight of the large catkins at the ends of the twigs gives the branches a graceful, slightly pendent habit. In its native habitat *A. oregona* attains a height of about forty feet to fifty feet.

A pleasing contrast to the American tree is *A. firma*, the second species illustrated, which is a native of Japan. The catkins are 2 inches to 2½ inches long, and thicker than in most of

country. The varieties are increased by grafting, using small plants of *A. glutinosa* as a stock. For the lakeside and in the pleasure grounds and woodland where the soil is not too dry, the Alders are very attractive trees. Generally speaking, the trees are of moderate dimensions, and in consequence a tree or two may be fittingly planted in gardens of no great size.

A. O.

HARDY ASIATIC PRIMULAS, NEITHER CHINESE NOR HIMALAYAN.

(Continued from page 180.)

P. Juliae (Kusnetzow).—Although only of recent introduction, seeing that it was discovered in 1901, and first flowered in this country in 1911, *P. Juliae* is already highly favoured by all who have grown it. It comes from the Caucasus, and is one of the moisture-loving Primulas; it is quite an easy subject to cultivate. It belongs to the *Vernalis* section of Pay, although Professor

Balfour does not think it should be so placed. It is a very hardy plant, with membranous, rounded-petioled leaves, and a plentiful supply of reddish flowers showing just above the leaves. Cultivation: Any soil and any position seem to suit it, but it does best in good rich soil in shade.

P. Kaufmanniana (Regel).—This has pubescent, petiolate rounded, lobed leaves and scapes bearing a number of rose violet flowers. It comes from Turkestan, and is amenable to the same treatment as *P. cortusoides* and other members of the section *Cortusoides*, to which it belongs.

P. longiflora (All.).—Although recorded from Armenia and the Caucasus, *P. longiflora* is really European in its area. It is a well-known plant in our gardens, and need not be further mentioned at present. Cultivation: The treatment recommended for *P. farinosa* will suit it.

P. luteola (Ruprecht).—Few people are

miserable, and the flowers are always destroyed by frost and rain. It loves shade and moisture. It comes from Layistan and was introduced about 1896. Professor Balfour places this plant in a separate section—that of *Megaseæfolia*—instead of following Pax and including it with the *Carolinella*.

P. nivalis (Pallas). — Pallas' *P. nivalis* has nothing whatever to do with the garden *P. nivalis*, which is correctly only *P. hirsuta nivea*, and is quite a distinct thing from the Asiatic *P. nivalis*. The latter belongs to the *Nivalis* section, and *P. hirsuta* to the *Erythrodosa*. *P. nivalis* and its microforms are widely dispersed, and are found in one or more forms from the Caucasus, Turkestan, Afghanistan and the Himalayas to the Altai and Baikal districts. It is a good grower, with oblong-elliptic, crenate-denticulate leaves, and scapes carrying umbels of purple flowers on short pedicels and with greenish purple calyces. It has a preference for moist places.

GARDEN CACTUS DAHLIAS.

THIS term is applied to those varieties that are noted for their freedom in flowering and their stiff, erect stems, which carry the flowers well above the foliage and thus produce a decorative effect in the garden. The exhibition Cactus Dahlias cannot produce a garden display, for they have to be thinned out in growth and the flowers disbudded to produce huge blooms. Naturally, the stems are not strong enough to support these large flowers, which weigh them down and so destroy the effect in the garden. Some of the best exhibition sorts will, if allowed to develop more naturally, produce a fine effect. I just point this out to show that both exhibition and garden types cannot be grown on the same lines, for one is to produce a mass of flowers for the garden, while the other is to produce large exhibition blooms.

At this season most amateurs are looking through their catalogues, endeavouring to make a selection of varieties for an autumn display. I am afraid catalogues do not help them very much in this respect, for as a rule they are abbreviated copies of the raisers' descriptions. Now, a raiser mostly describes his new varieties very fully and sees them in their best possible colours. After the first season, however, the descriptions get cut down, with the result that they are most difficult to follow. I am also very much afraid the lists copied down at flower shows are very misleading to those amateurs who want a garden display, for as a general rule one only sees the best exhibition sorts, and these are not adapted to the object in view. Again, I am quite sure the majority of Dahlias do not receive the cultural details they require, for it is quite a common sight to see a huge plant tied to a single stake like a bundle of faggots. Under this system the plants cannot be other than unsatisfactory.

Now, to produce plants that will commence to flower in August, or even earlier, it is essential that an early start should be made. The plants

should be purchased in April, when they are well rooted; this enables the cultivator to repot them into 5-inch pots, thereby securing larger and stronger plants; it also prevents them getting checked by being root-bound and starved, and at the same time we have a stronger plant to resist the attacks of slugs. If room is limited in a cool greenhouse, the plants can be relegated to a cold frame, where they grow steadily and sturdily; but they must be protected from frost. Nothing is gained by planting too early, and the last week in May or the first week in June is quite soon enough, according to the district. There are many people who are under the impression that the Dahlia requires a very rich soil; this is not so, as such soils usually produce a mass of soft, succulent growth which does not produce good flowers. Really, a soil that grows good vegetables will make an ideal Dahlia soil. A little decayed manure can be mixed with the soil in the station prior to planting; this will help to conserve the

PRIMULA JULIA, A RARE HARDY SPECIES FROM THE CAUCASUS, WITH REDDISH BLUE FLOWERS.

sufficiently acquainted with the East Caucasus, Turkestan and Daghestan *P. luteola*, which has been cultivated since 1867, and is one of the best of our hardy Primulas. It has leaves of a lanceolate-elliptic shape, obtuse and denticulated, with the blade narrowing into a petiole, the scape rising well above the leaves, and bearing a many-flowered umbel of pale yellow flowers. *P. luteola* is a native of damp places and loves a moist soil, although it is not too fastidious. Cultivation: Moist situation in half shade. Soil rich, with a good deal of leaf-mould

P. megaseæfolia (Boiss.).—This is a very distinct plant, with large, broad, cartilaginous leaves and bearing its flowers in umbels, sometimes one above the other. These are called rose, but they are more properly magenta rose. The colour is not specially acceptable to many, but, as this Primula flowers in the winter, it is an acquisition for a slightly heated greenhouse or a warm district. In the colder parts, if grown in the open, it looks

P. saxatilis (Kom.).—For garden purposes there is little to distinguish *P. saxatilis* from *P. cortusoides*, a point which has already been discussed under *P. cortusoides*. It has been suggested that *P. saxatilis* is only a microform of the last named, and this is possibly correct. *P. saxatilis*, however, as has been previously mentioned, has longer pedicels. It is quite an easy plant to grow in moderately heavy soil, and gives a good supply of its reddish flowers.

P. sibirica (Jacq.).—This has already been considered among the Chinese species, to which reference may be made for further particulars regarding it.

P. Sieboldii.—This also has been previously discussed when writing of the hardy Japanese Primulas, so that it is unnecessary to mention it further. Other sections of hardy Primulas will be dealt with in subsequent articles

Morelands, Duns

JOHN MACWATT.

moisture in the soil, while a small handful of superphosphate of lime scattered in the soil around the plant is helpful in building up a strong plant. Most Dahlias will occupy a space 4 feet square during the season, but it should always be remembered that a Dahlia can be grown in a smaller space if desired; it is only a question of thinning and pruning.

Before planting, the central stake should be firmly driven in the soil and the plant put out with a spade, not a trowel; the latter does not disturb the ground sufficiently. Later in the season each plant should have three or four smaller stakes driven round it, and the plant tied out to each stake; this will admit light, air and sun to every part of the plant, and thus secure that mature growth so essential to the production of good flowers. Now, as to thinning out the growths.

In nearly every case, as far as theactus section is concerned, this thinning out is necessary. Part of the lateral growths should be removed from each main stem, leaving, however, sufficient to make a good, full plant. It requires very little practice to enable the grower to acquire this knowledge. Those who have been in the habit of relying on the single stake in years past should adopt the four-stake system, for I feel sure, if once adopted, they would never return to the old system. If large flowers are required, only one bud should be left to each growth; otherwise, allow all the buds to develop; but partial disbudding of the flowers is desirable in most instances.

As the Dahlia has to make its growth very rapidly, it will occur to every cultivator that, to obtain the necessary food supply, plenty of moisture is required; so during dry spells the Dahlia should receive a good supply of water weekly, which is infinitely preferable to more frequent applications. Liquid manure may be given, but it is not necessary in the majority of cases.

The Question of Varieties is the all-important one, and as far as actual colours are concerned the best varieties are quite a matter of taste; but all should have the correct habit. The following have been selected as some of the best in a large collection: Amos Perry, rich scarlet, 3 feet; Duchess of Sutherland, delicate blush pink, 3 feet; Mrs. Douglas Flemming, pure white, 3½ feet; Glenda, rosy crimson, 3 feet; Conquest, deep crimson, 3 feet; Mrs. Forrester Paton, crimson scarlet, 3 feet; Mrs. Charles Foster, rosy pink, 3½ feet; Richard Box, yellow, 3½ feet; Mary Purrier, crimson scarlet, 3½ feet; Record, yellow, shading to orange red, 4 feet; Sweet Briar, pink, 4 feet; Edith Carter, yellow, tipped rosy carmine; Sportsman, bright scarlet, 4 feet; Millicent, orange carmine, 2½ feet; Sherlock, orange, 3 feet; Johannesburg, amber gold, 4 feet; Lustre, crimson with darker centre; Mauve Queen, mauve, 3 feet; Nellie Riding, crimson, tipped white, 3 feet; White Ensign, 3 feet; Hon. Mrs. Greville, orange yellow, 4 feet; Florrie Wells, rosy crimson, 3 feet; and Vivid, intense scarlet, 3 feet. J. B. RIDING.

THE JAPANESE PLUM. (PRUNUS TRIFLORA.)

ALTHOUGH not very widely known, the Japanese Plum, or *Prunus triflora*, to give it the correct botanical name, is one of the most glorious of all spring-flowering trees. The flowers, which open as the Almond trees are passing out of bloom, are white, and so freely are they produced that the loosely formed sprays are wreathed in bloom to their very tips. The accompanying illustration gives one a very good idea of its manner of growth and flowering; moreover, it clearly emphasises the value of planting early flowering trees with light-coloured flowers against a background of deep green conifers or other dark-foliaged trees.

There are many varieties of the Japanese Plum, and as commercial fruits they are appreciated, but as flowering trees their exceptional beauty appears

THE JAPANESE PLUM (PRUNUS TRIFLORA). THIS IS ONE OF THE MOST CHARMING OF SPRING-FLOWERING TREES.

to have been overlooked. *P. triflora* must not be confused with *P. triloba*, a beautiful wall shrub, the flowers of which in many gardens are now (April 7) just opening; neither must it be confused with the Japanese Cherry (*Prunus Pseudo-cerasus*), a glorious flowering Cherry, popular both in Japan and in this country, and rightly regarded as one of the most beautiful introductions we have had from that land of flowers. *P. triflora* is a native of China, and was probably imported into Japan. Observations of more than usual interest on the Japanese or Cape Plums appeared in THE GARDEN for March 14, page 135, where the writer, Mr. E. A. Bunyard, referring to the adaptability of these fruits to the English climate, says that experiments so far lead to no hope of this possibility.

THE EARLY FLOWERING MAGNOLIAS.

THESE are few families of plants which possess so many admirable features as the genus *Magnolia*, for not only are the flowers of most of the species of an exceedingly attractive character, but the leaves are also handsome, while in many instances the fruits are brightly coloured and showy. Moreover, they bloom with considerable freedom, and many kinds rarely fail to produce a wealth of blossom when the flowering-time comes round.

The species may be divided into two distinct groups by reason of the time of flowering. The first group is made up of those kinds which produce their flowers on leafless branches, and, the second, of the ones which bloom during the summer or after the appearance of the leaves. Perhaps of the two groups the former is the more noticeable, for the flowers open during late March and April, before the majority of spring plants are in flower. They are really better fitted for the Southern than for the Northern Counties, although even in the North some people contrive to obtain good displays of bloom by placing their plants against warm walls.

It must be borne in mind, however, that soil is an important factor towards the well-being of Magnolias. Warm and well-drained, yet naturally moist loam is the best kind to use, while a little peat or leaf-mould placed about the roots is appreciated. Root disturbance must be avoided as far as possible, for the plants are rather impatient of root injury, and often take some considerable time to re-establish after being transplanted. For this reason it is wise to carry out any transplanting operations during very early autumn or late spring, while the ground is warm. Neither is it advisable to do very much pruning. Pruning is not essential to success, and may well be left alone, unless a little shaping or the removal of a broken branch becomes necessary.

Magnolia conspicua, or the Yulan as it is sometimes called,

is one of the most beautiful of the taller-growing kinds. A native of China, it is said to have been introduced about 1789. In the neighbourhood of London numerous fine examples are to be seen in the open ground, where they form bushy-headed trees 20 feet to 40 feet high and as far through. Each year these trees are laden with pure white, fragrant flowers, each one about 4 inches long and 4 inches or 5 inches across. Sometimes the flowers are browned by cold winds or frost; therefore, when a position is being selected, it is wise to bear this in mind and choose a place where shelter from the north and east is available. Although less showy than the Yulan

M. obovata, another Chinese species, demands attention. Forming a spreading bush 8 feet or

so high, it bears showy purple blossoms; but it is as a subject for the hybridist that it is most highly appreciated. Crossed with the Yulan, a race of handsome hybrids has been raised, which bloom with the freedom of *M. conspicua* and grow into bushes 15 feet or 20 feet high. The flowers of the different kinds are stained more or less deeply with purple. Good ones are *superba*, *soulangeana*, *Alexandrina* and *Norbertii*. A fine example of *M. soulangeana* stands near an equally fine specimen of *M. conspicua* in the Azalea Garden at Kew. Even better examples of the last named are to be seen in the gardens at Syon House and Gunnersbury House.

M. Campbellii is a Himalayan species, and one of the most magnificent of all kinds; but, unfortunately, it can only be grown successfully in the mildest parts of the country. In its native country it attains the proportions of a large tree, and examples 30 feet to 40 feet high have been recorded in the British Isles. The flowers are often 9 inches or 10 inches across and rich rose or crimson on the outer side, paler within. They are borne with regularity in the gardens at Abbotsbury Castle in Dorsetshire, in Sir E. Loder's garden at Leonardslee, and in several other places.

M. Lennei is a handsome-flowered hybrid, its suggested parentage being *M. conspicua* and *M. obovata*; but there appears to be good reason to suppose that the former species and *M. Campbellii* are the parents, for both in size, shape and colour the flowers more strongly resemble those of the Himalayan than of the Chinese species. Moreover, it blossoms several weeks later than the other hybrids previously mentioned. It is a magnificent sort, and should find a place in every Southern garden. *M. rustica* and its form *flore rubra* are presumably of similar parentage, the flowers being large and rich in colour.

M. stellata has been one of our choicest spring-flowering shrubs for the past fifteen or twenty years. A native of Japan, it is usually met with as a shapely bush 4 feet to 8 feet high, but plants are sometimes found exceeding 12 feet in height and 12 feet in diameter. The star-like, glistening white flowers are made up of numerous narrow petals, and they are very fragrant. A pink-flowered form is also known. Except in stature, the Japanese *M. Kobus* has much in common with *M. stellata*, for it is difficult to distinguish the leaves apart, and, except for fewer petals, the flowers are similar in shape and size. It, however, grows into a large tree.

One of the finest new-comers is found in the Chinese and Japanese *M. salicifolia*. This is a free-growing plant which in its native country is said to grow from 15 feet to 20 feet high. Its leaves are rather small and narrow, and the white, fragrant flowers are somewhat after the style of those of *M. stellata*, but rather larger and composed of fewer petals.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Clematis Armandii. A novelty, and an acquisition to boot, and without doubt the finest addition to the genus for many a day. The species has frequently been exhibited previously, but never in the fine condition as on the present occasion. It is hardy, more or less evergreen, early to flower, with axillary clusters of flowers of the purest white. It is a Chinese species, whose merits have been fairly tested prior to being exhibited. From the Hon. Vicary Gibbs, Elstree, Herts.

AWARDS OF MERIT.

Rhododendron fastigiatum.—Miniature bushes were exhibited of this recent novelty from China,

golden yellow, flushed near the edges with bronzy red.

Primula Bookham Gem.—Perhaps the largest of the intermedia or viscosa class yet seen, both flowers and cross presenting a very handsome appearance. The violet colour is rendered conspicuous by a pure white eye. These came from Mr. James Douglas, Great Bookham, Surrey.

Columnnea glabra major.—A beautiful old-fashioned greenhouse flowering plant of trailing habit belonging to the Gesneraceæ. The smooth, shining leaves are an inch or so long and somewhat fleshy in texture, the brownish stems being of a like texture. The flowers are brilliant scarlet, and appear in the axils of the leaves at the ends of the branches. Admirably adapted for basket decoration in the greenhouse. From Elizabeth Lady Lawrence, Dorking.

Anthurium conchiflorum.—This very striking hybrid resulted from a cross between *A. scherzerianum* and *A. chamberlainianum*, the former being the seed parent. Judged by the large, handsome foliage, many might have suggested *A. andreanum* as one parent, though we are informed the seed parent was an exceptionally strong variety of the species named. The brilliantly coloured spathes are of crimson scarlet, with upturned sides, which, we imagine, suggested the above name. Sent by Lady Lawrence, Dorking.

Osmanthus Delavayi.—A small-growing, delightfully fragrant evergreen hardy shrub, whose pure white, starry, Bouvardia-like blossoms are freely produced in axillary and terminal clusters. The dark green entire leaves are an inch or so long, and have obscurely crenated margins. Altogether a delightful plant, whose fragrance alone will assuredly render it popular with all. From the Hon. Vicary Gibbs, Elstree. This beautiful flowering shrub was illustrated in THE GARDEN of April 15, 1911.

Prunus Pissardii blirieana flore pleno.—An unfortunately overwhelming number of names to a very beautiful plant, which is quite distinct from the double form of the type. The foliage is of deep bronzy hue, the semi-double

flowers of a warm Apple blossom pink. Shown by Mr. R. C. Notcutt, Woodbridge.

NEW ORCHIDS.

Two first-class certificates were granted, one to *Cattleya Tityus* The Shrubbery Variety, shown by F. Menteith Ogilvie, Esq., and the other an exquisite *Odontoglossum* hybrid from Lieutenant-Colonel Sir George Holford's collection. Two *Odontiodas* gained awards of merit, one from Mrs. Norman Cookson named Clive, and the other from M. H. Graire, 5, Rue St. Fuscien, named *graireana splendens*.

The Daffodils to receive awards of merit will be referred to in the Rev. Joseph Jacob's notes next week. The foregoing plants were shown on April 7 before the Royal Horticultural Society.

MAGNOLIA SALICIFOLIA, A NEW SPECIES FROM CHINA AND JAPAN, NOW FLOWERING AT KEW.

whence seeds were sent by Mr. E. H. Wilson. The plants, of 6 inches or so high, were just loaded with violet blue trusses of flowers, which have brownish anthers. The plants shown were from three to five years old from the sowing of the seed. A large bush of it would be most effective in the rock garden. Exhibited by Mr. G. Reuthe, Keston, Kent.

Rose Constance.—A high-class novelty belonging to the pernetiana set, and raised by M. J. Pernet-Ducher. The flower-buds are of exceptional length, rich yellow in colour, the outer petals just touched with red. The foliage is handsome and shining, the wood heavily beset with spines. From Messrs. Beckwith and Sons, Hoddesdon.

Auricula Gordon Douglas.—A very handsome fancy sort with perfectly formed flowers of a rich

GARDENING FOR BEGINNERS.

THE AUCUBA: ITS CULTIVATION AND PROPAGATION.

there is one evergreen shrub more prominent than others as particularly adapted for cultivation in confined town and suburban gardens, it is the

—LARGE CUTTINGS MAKE USEFUL PLANTS AS SOON AS THEY ARE ROOTED. THE CUTTING SHOWN ON THE LEFT HAS ALREADY PRODUCED ROOTS.

Aucuba. A native of Japan, *A. japonica* has been cultivated in British gardens for about one hundred and thirty years. In growth, size and colour of the leaves it is a very variable shrub. The numerous forms of Aucuba have been given varietal names by nurserymen, and it would not be difficult, should one wish it, to obtain a collection of at least twenty named sorts. In habit the plants vary from 2 feet to 10 feet in height. There is a very marked difference in the size and colouring of the leaves. Some flowers prefer the large, shiny pale green leaves beautifully spotted with yellow; others choose the rich, shiny green leaves, suggestive of the laurel. In some sorts the edges of the leaves are entire, while in others they are elegantly toothed. It seems difficult to believe, but it is a fact, that this Japanese shrub thrives better in the smoky atmosphere of our large towns than our own native evergreen shrubs. Shade does not harm the Aucuba; it will thrive under all trees as well as the Ivy. Such a good-natured plant is the Aucuba that, in addition to thriving in most positions, it will also grow in nearly all soils. The Aucuba makes a beautiful and attractive lawn specimen; it is also useful as a screen, and an ideal subject for the shrubbery border. Thousands are sold in pots annually by nurserymen for window-boxes, and, when too large for pots, transfer them to tubs for the terrace and steps, or plant out in the garden. This Japanese shrub is also interesting, there being two sexes. The male and female flowers are borne on different plants, not like most of our favourite shrubs, both on the same plant. In addition to its attractive foliage, the female Aucuba bears ornamental berries larger than those of the Holly; but to get these one must grow Aucubas of both sexes, as the pollen from the flowers of the male plant is necessary to fertilise those of the female, otherwise no berries are produced.

A considerable trade is done with small Aucuba plants, covered with berries, in pots. These are grown in greenhouses and artificially fertilised, but this is not necessary outside; as long as there are plants of both sexes, the wind will distribute the pollen.

Propagation from Cuttings is the usual and quickest means of increase, though seeds also may be sown. Quite large branches root readily in a close propagating-frame, preferably with a little bottom-heat. One of these, made ready for insertion, is shown in the illustration, and another rooted ready for potting or planting out in the border. Under glass, Aucuba cuttings may be inserted at any time. In the open border October and November is the best time to put in cuttings. In a moist propagating-frame the cuttings will root in any light material—sandy soil, fibre, leaf-mould or coarse sand. By inserting

large shoots such as those illustrated, good plants are available for potting up in two months suitable for use at once in a window-box. The plant illustrated in the pot is a female, with the flowers just setting after pollination. At the side a shoot with berries is shown. Aucubas flower outside during March and early April.

O. R.

NOTES ON VIOLAS.

Uses.—Violas, or Tufted Pansies, are among the most serviceable plants for use as edgings or to fill in spaces round taller specimen plants; they also mass well in small "dot" beds of distinct or harmonised colours on lawns.

Advantages.—Of the many advantages possessed by Violas as garden plants, perhaps the chief one is to be found in their hardihood. Unlike some varieties of the old favourite Pansy, they will stand our winters well, and, commencing to bloom in March, will continue without intermission until well into November, being therefore in season for nine months out of the twelve.

Culture.—When putting out the young plants which have resulted from cuttings, it is well to pinch out the tops to induce bushiness, and to keep the buds picked off for a time to induce multiplication of rootlets to stand the strain of future dry weather. Fork deeply under each plant, mixing in some old manure, with a dash of old soot and bone-meal. Each plant should have an 8-inch space. Plant

12 inches apart and restrict the stems to 3 inches, or at the most 4 inches, with a maximum number of two buds to each stem. Some exhibitors stake each plant, but my experience is that the most satisfactory results are obtained by allowing the natural form of growth. Violas are moisture-loving plants, and therefore a good soaking over and under once a week during warm weather is necessary. Occasional applications of weak soot-water and weak manure-water are beneficial, especially if exhibition blooms are required.

Selections.—For exhibition: Agnes Kay, Moseley Perfection, Mary Burnie, Lady Knox, G. C. Murray, Gladys Finlay, A. S. Frater, Nettie McFadyen, Bethea, Willie Farmer, Kate Cochrane and Jessie Harrison.

For bedding: In addition to the above, Mrs. Chichester, Edina, Maggie Mott (scented), Swan, Lark, Alexandra, Redbraes Yellow, White, or Bronze, Kitty Bell, Lady Clonbrock and Hector McDonald.

For massing: Centre, Lady Knox; border, Edina. Centre, Mrs. Chichester; border, Kitty Bell. Centre, Swan; border, Maggie Mott. Centre, Moseley Perfection; border, Bronze Kintore. Centre, Bethea; border, G. C. Murray. Centre, A. S. Frater; border, Nettie McFadyen.

One colour beds: Mrs. Chichester, Lady Knox, Lady Clonbrock, A. S. Frater, Swan, and Maggie Mott.

B. W. LEWIS.

A NEWLY ROOTED CUTTING PRODUCING FLOWERS. A BEERED PRAY IS SHOWN IN THE FOREGROUND

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Melons in Frames or Pits.—Very good fruit may be grown in frames during the summer, but there should be no delay in making up the hot-beds so that the plants may become established before the season is too far advanced. The bed may consist of stable litter and leaves in equal parts, and should be trodden lightly. The soil should then be placed in good mounds in the middle of each light, and, when warm through, be made tight by ramming. One plant is sufficient for each light, and should be stopped beyond the fourth eye, so that four shoots may be trained from each plant. Peg the shoots to the soil, and when they have made good growth the tops may be pinched in order to encourage side shoots, on which the young fruits will appear.

Cucumbers.—Early plants will now be fruiting freely, and should receive liberal supplies of manure-water at the roots. Top-dress the bed as often as the young roots push through the surface. Loam and decayed manure in equal parts may be applied.

Plants Under Glass.

Cyclamen.—Seedlings raised in the autumn should now be ready for potting into 3-inch pots. The soil for this purpose may consist of loam and leaf-soil in equal parts, with sufficient sharp silver sand to keep it in a porous condition. Pot moderately firmly and grow in a temperature of 60° quite near the roof glass. As the season advances they may be transferred to clean, well-ventilated frames, where protection from strong sun can be applied. By the beginning of July they should be ready for potting into their flowering pots. Water must be sparingly given until they are established, after which a liberal supply must be provided, and the syringe freely applied in the afternoons to keep them free from insects.

Hydrangeas.—Autumn-struck plants which are approaching the flowering stage should be freely watered with liquid manure. Keep them near the glass in a temperature of 60° until the flowers are fully developed. Old plants intended for summer flowering should be allowed to remain in a cool structure, and watered freely with liquid manure.

Amaryllis.—When the flowering season is over, the plants should be assisted in their growth by some approved stimulant in order to secure the best results another year. When the plants have finished their growth, gradually give more air and allow them to rest in a quiet, cool structure.

Clivias.—Plants which have finished flowering should not be allowed to suffer from the want of water. Give frequent applications of liquid manure throughout the summer, and do not pot the plants before it is necessary. As the season advances, the manure may be discontinued and the plants grown in a cool structure.

The Flower Garden.

Pansies and Violas.—Plants which were propagated from cuttings in the autumn should now be planted in their flowering quarters. Both the Pansy and Viola thrive best in deep, rich soil and a somewhat shaded position where they are not exposed to the full sunshine during the hottest part of the day.

Lobelia compacta.—Seedlings should be pricked into boxes or frames as soon as large enough to handle, for if once allowed to become drawn they will be of very little value. When they have become established and are growing freely, the tops may be clipped in order to induce side growths.

Mignonette.—Frequent sowings should be made during the next two months to ensure a continual supply of flowers throughout the summer and autumn. Keep a sharp look-out for slugs, which are very fond of the young seedlings, and dust the plants with soot in the early morning while the leaves are damp.

The Lawn.—Grass is growing rapidly now, and should be mown frequently, as nothing is gained by allowing too long an interval in this matter. Nothing is saved in labour, and the lawn itself will suffer in consequence. Trim the verges frequently, as neglect in this matter tends to give the garden an untidy appearance.

The Hardy Fruit Garden.

Peach and Nectarine Trees on walls will now require careful attention. The disbudding of these is an important matter, and should be accomplished a little at a time, commencing at the top of the tree and rubbing off the shoots at the back of the branches, as well as those directly in front, then others in unsuitable positions; but avoid severe thinning of the shoots at one time, for it is safer practice to go over the trees at intervals of a few days until the work is completed, and it is only by careful study of the requirements of each tree that the work can be successfully accomplished.

Insect Pests.—Aphides are a most troublesome pest, and generally make their appearance as the trees are passing out of flower, when it is difficult to adopt measures strong enough for their destruction without injuring the young growth; but as soon as these insects are noticed, no time should be lost in syringing the affected points with some approved insecticide, and the trees should be thoroughly syringed with clear soft water early in the afternoon when the outside temperature is favourable.

The Kitchen Garden.

Herbs.—The present is a good time to make new plantations of Mint. If single cuttings are planted in rows a foot apart and the same distance between the plants in the row, they will soon make good, strong plants, and will quite cover the ground before the end of the season. Tarragon may be treated in the same way, but should be allowed double the space between the rows.

Thyme.—Young seedlings should be planted in light, rich soil and allowed a foot between the plants each way.

Marjoram should now be sown in gentle heat. Prick off the seedlings as soon as large enough to handle, and grow in a slightly heated pit. When large enough, they should be planted on a warm border. Lift and pot in September for winter use.

Basil may also be sown now in heat and the seedlings transplanted as soon as large enough. A warm south border should be selected for summer supplies, and a sowing made in August for winter use.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Brassicas.—When the seedlings are large enough to handle, they should be pricked into a prepared bed about four inches apart. In making up this bed it will be wise to put up a temporary shelter with some rough boards, so that the young plants can be protected for a time. A few Spruce branches or a garden net could be used for this purpose. One might think this a little too much work to devote to such common things as Cabbage or Cauliflower. At the same time, they will well repay for the extra labour.

Vegetable Marrows.—Too often these are grown far too large, which renders them so coarse and difficult to cook. Fortunately, there are small varieties now on the market which come early to maturity, and if possible have a more delicious flavour than some of the older sorts. One has only to try a dish of Sutton's Table Dainty to realise how excellent Marrows are, after all. Seed may be sown now and treated almost as one would frame Cucumbers. They will give a good return from a small outlay.

Growing Crops.—These will be greatly assisted with an occasional application of nitrate of soda sown between the rows. There is no hard-and-fast rule as to the quantity to apply, but an open handful to every 3 yards will be a good dressing. Afterwards stir up the soil with the Dutch hoe.

The Flower Garden.

Half-Hardy Annuals.—Those that were sown last month will be almost ready to prick out, and at this stage it is imperative that they should be placed near the glass, whether in greenhouse or frame. It is also important that they should not be allowed to become dry. When it is necessary to water the seed-pans, it is best done by standing them in a tub containing a few inches of tepid

water. Prick out the seedlings in most cases as soon as they can be handled, and in preparing soil for this purpose it should be of a nature that roots can cling to, so that when moved to their flowering quarters they do not suffer much check.

Spraying Roses.—As a preventive of mildew on Roses, one should spray them immediately after they have been pruned, and all the dead leaves and rubbish cleared away. There is no doubt that much could be done to check this fungus by timely spraying. For many years I have used Bentley's Mildew Destroyer, which I consider an excellent fungicide. Where, however, this is found to be ineffectual, one might try sulphide of potassium. An ounce dissolved in soft water would be strong enough. Apply this with a fine spray to the affected plants in the evening, going over them the following evening and syringing with clear water.

Sweet Peas.—Plants that have been grown in pots and boxes may now be transferred to their flowering quarters, provided they have been hardened off. In planting in rows I find it advisable to draw a drill about four inches deep and plant in the bottom. The young plants thereby get a certain amount of shelter. At the same time they should be protected from cold winds by small pieces of Spruce on both sides of the row until they are sufficiently strong to stand the weather. To guard against sparrows and slugs, give the plants a dusting of old soot or lime, and repeat this from time to time.

Auriculas.—Last year's seedlings should now be transferred to their flowering quarters, which, by the way, should not be in the full glare of the sun. Seed might also be sown now, and, like older plants, the young seedlings should be well shaded from the sun.

Plants Under Glass.

Plumbago rosea.—No time should be lost in introducing the old plants into heat to produce cuttings. I find they root very freely, and anyone wishing to have a display of flowering plants in midwinter would do well to grow a good batch of this Plumbago. It is much more graceful in habit than any of the winter-flowering Begonias, and, if anything, the flowers are more telling. They are of a fine deep rose pink colour.

Gloriosa superba.—This lovely stove climber, which still maintains its popularity, will now be starting into growth. Where the plants are grown in pots, the tubers should be shaken out of the old soil and repotted in a mixture of good turfy loam, sand and a little charcoal. Place them in the warm end of the stove until they get a start, afterwards moving them to where they are to flower. I remember seeing a very pretty arrangement in which the Gloriosa clothed the roof of a fernery. The effect was really fine.

Chrysanthemums.—All the young plants may now be placed in cold frames, taking precautions to have some covering material handy in case of extremely cold nights. Endeavour to keep them as near the glass as possible, and admit air with caution for a few days. Afterwards the sashes might be removed on fine days.

Fruits Under Glass.

Planting Young Vines.—Where the young Vines have been grown in pots, preparations should be made for planting, that is, if they have been previously started into growth. The soil should be entirely shaken from the roots, and perhaps the best method of doing this is to place the ball in a tank of tepid water, when the roots will soon get disentangled. In planting, spread out the roots carefully and cover with some prepared soil, finishing off by giving them a slight watering. As the young growths will be inclined to flag until the roots get a hold of the soil, the house should be shaded just above them, when they will very soon recover from the shift. Vine eyes that were rooted in turves may either be planted now or left until well on in May. Many growers prefer doing this as late as June.

Figs.—On early trees the fruit will now be swelling, and where they are confined in pots or built receptacles they may be given liberal supplies of liquid manure. Constant attention must be paid to stopping all shoots about the fifth leaf to avoid overcrowding and also to assist in swelling the fruit.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linthgow.)
Hopetoun Gardens, South Queensferry, N.B.

DAFFODIL NOTES.

Past History.—Owing to Easter and its attendant alteration of the ways of THE GARDEN, I cannot deal with the Royal Horticultural Society's show on April 7 as I otherwise would have done, but I am taking the opportunity to dip into the past. Yes, "to dip into the past," in this busy, bustling Daffodil time, when everyone, from the editor downwards, is athirst for something "practical," or what they call practical, for this is a word which, like some of those most judiciously recorded prayers in the Book of Common Prayer, may mean one thing to one person and another to another. I call the past practical for the very simple reason that a visitor's enjoyment is always greatly increased when the cicerone is able to talk about the plants he is showing. Go round anyone's garden but your own, alone—how dull! Go round with an owner who can tell you little more than you may read for yourself on the labels—how annoying! how irritating! On the other hand, go with the man full of historical and "cultural" information, who can tell you of the coming of the Dahlia or the first appearance of the Fuchsia, and talk pleasantly and banteringly of the spelling of the one and the pronunciation of the other—how different then is the tour of that garden! We all know it.

The Daffodil gives us plenty to talk about. The word itself has a derivation which so far has baffled the understandings of the learned—"affodil," perhaps, but that "big, big D" ("My Garden in Spring," page 120). Why that? Here is a fine colony in some damp part of the rockwork of the curiously shaped cyclamineus. It is an opportunity for a digression on the old flower picture-books of a long-distant past. Some figured this quaintness. Not many tens of years ago, everyone thought it as much an effort of the imagination as the blue Daffodil in Miss Silberrad's interesting novel of Dutch life in the bulb districts, "The Good Comrade." There it is in Pierre Vallet's "Le Jardin du Roi très Chrestien Loys XIII." (1623), under the title *Narcissus Hispanicus*. But it became so entirely lost sight of in gardens and in its wild habitat that no less an authority than Dean Herbert called it "an impossible plant." Then, somewhere about 1886, it was rediscovered by Mr. A. W. Tait of Oporto, to the amazement of all.

Another fruitful source of conversation might well be an ancient catalogue and the changes which have come about in its varieties during the short life of the plant as a popular garden flower. I have an early list of Messrs. Barr and Sons, dated 1887, before me now, also one of the same firm's of 1912. The twenty-five years' interval has revolutionised both of them—the flowers and us. We have been educated, I suppose I might say, and the flimsy perianths and the small starry forms of the earlier hybrids, which astonished and pleased the first Daffodillers, as, for example, Mary, Robin Hood, Acis, John Stevenson, John Bull, Shirley Hibberd, King Umberto and numbers of others, are for the moderns of to-day mere words—catalogue names suggesting nothing. And they have been improved, we say and think. White Lady, Noble, Evangeline, Lucifer, Blackwell, Whitewell, Olympia and Lady Margaret Boscawen are now upon the scene. We point them out with gusto and pride, and if we want to digress and turn our little plot into a sort of ancient Athenian lecture hall, a talk about "What an improvement" will make it wondrous like.

"Improvement is a getting away from Nature," says the host. "Yes," says the visitor, "it is *But* you—" And so on, and so on. There you have done it, and interesting and heated arguments flow.

It may happen, however, that we stop before a Challenger or a Cræsus. Without being purse-proud—for we need not mention the fifty guineas that those two bulbs cost us—we may talk of prices: how "Peter Barr" actually found purchasers at fifty pounds a bulb; how Emperor, probably the finest of all Daffodils, never seems to have been valued at that number of pence; how the raiser's family sold the stock of *Horsfieldii* for a shilling apiece. There is much of interest to be said of prices.

No less in bulbs than in cut flowers in the market. My friend, Mr. William Poupart, doubtless often looks back on the halcyon days of the past, to the seventies when he and others—dear old James Walker for one—began to develop this important industry. The fear and trembling with which he bought *ornatus* and refused *Horsfieldii* were only possible to a pioneer. Then other firms joined in, for prices were high and alluring. Some say now that the game is up and that present prices are almost unremunerative. But from what we have been "forced to hear," it is not played out yet. A Napoleon comes along in the person of Walter T. Ware, who, first of all, has the sagacity to know a good thing when he sees it; who, secondly, knows how to get over a poor "unsophisticated" Dutchman; who, thirdly, knows how to wait; and who, fourthly and lastly, knows how to put flowers on the market and bulbs into traders' catalogues, with, I feel certain, not a little monetary satisfaction. If you have it in your garden, you might point to Queen of the West as a supreme example of his skill in the masterly handling of his forces.

Possibly, however, we are seedling raisers, and at last we are in front of some of our very own. My eye! How the most silent tongue can wag them! Only if the friend who accompanies us is not a hybridist himself, let us be content with generalities or broad outlines, for he will not want to know the pedigree of this and that right away from Backhouse and Leeds. Those details will not interest him. Thus we might ramble on and on, each host naturally talking of those points and parts of Daffodil history or cultivation which "find" him or appeal to him most. So is a visitor's pleasure increased and his interest tickled, and who knows but what in the end he may be caught. Let us hope so. Surely, these are some of the things to be aimed at in life—a pleasant smile, an insinuating way, a good bedside manner, an unaffected politeness, some Daffodil knowledge and the facility of imparting it as one takes a friend round one's garden. JOSEPH JACOB.

THE EDITOR'S TABLE.

New Freesias from Holland.—It is with considerable pleasure that we have received from Mr. C. G. van Tubergen, jun., Zwanenburg, Haarlem, some of his charming new Freesias. The colour shades of these are really wonderful, and in some unlike anything we have ever seen before. For instance, a variety named *La Charmante* is a glorious mixture of rose, golden yellow and apricot, that must be seen to be fully appreciated. *Amethyst* is a beautiful shade of lavender blue; *Canary*, deep golden yellow; *Monette*, rosy

cerise and cream; *Robinella*, deep claret red; and *Apogée*, very deep golden yellow. The size of the flowers is fair, and in most instances they are of good shape. We congratulate Mr. van Tubergen on his success with these charming and fragrant flowers.

SWEET PEA NOTES.

AS these notes are being penned, the glorious warm rays of the sun, the hum of insects and the songs of birds kindle anew the hope that at last spring has arrived. But what a March! Could the weather have been worse? Rain, rain, and rain again, and the hearts of Sweet Pea growers dropped almost to the point of despair as they beheld their soil waterlogged; and even if the good weather continues, many days must pass before the land in this district is workable. As a strong advocate of autumn trenching, one derives a glimmer of satisfaction from the recent bad weather, as it has conclusively proved the advisability of getting the preparation of the soil done as early as possible. The plants have sadly suffered through lack of sun, and those growers who have plants under glass growing for exhibition complain of soft, attenuated growths. The ordinary gardener whose plants are thus suffering may help them by giving them plenty of air, and at the same time keeping the fires going; but with a few days' sun and warmth I do not think one need worry. All will yet be well.

What does concern many is the fact that their seedlings are suffering in the boxes or pots and the ground unfit for planting out. Hard as it may seem, my advice is to wait until the soil is in a fit condition and workable. The check the plants are sustaining now can be minimised by giving them plenty of air and an occasional watering of very weak soot-water; but you risk total failure if you plant in wet, sticky soil, while, to attempt to work a heavy soil when wet, borders on madness, and its utility is nil.

Method of Planting Out.—The question of what constitutes a check is a very controversial one, and often too much stress is laid upon matters of very little moment. The ideal way of raising plants is singly in a pot, and thence to transfer them to their growing quarters by the following method: The day previous to the planting out well water the plants. This enables the entire ball of soil to be easily knocked from the pot, when the hole which has been made by a trowel is ready to receive it. Place the entire ball with the plant and twigs (these supports are essential) carefully in the hole prepared, and press the soil well round it. Do not be afraid of making the soil fairly solid, for Sweet Peas like a firm soil to dwell in. The foregoing process applies to all plants grown in pots. Many growers, however, raise seedlings in boxes, and each must be carefully separated from the other without undue injury to the roots. "But what a check!" says one, and this is the controversial point. If the following plan be adopted, there is little or no check: I have already emphasised the fact that no planting must be done unless the ground is in a good working condition, and this is easily tested. Take up a handful of soil and squeeze it in the palm of the hand. If it becomes a sticky, wet mass, then it is not in a fit condition for planting; but if it easily falls away and does not wet the hands, when the soil is ripe for receiving the plants.

If the plants are to be grown in rows, then make a deep drill with a spade and arrange the plants about a foot apart along the line, cover with soil and water in; this enables the roots to be entirely covered with soil, and leaves no spaces, so to speak. Then cover with more soil and press firmly, putting twigs for supports. Do not use a dibber, but always plant with a trowel. Single plants thus treated seldom show any signs of having received a check, and I am of the opinion that this is by far the easiest and most successful treatment for Sweet Peas for decorative purposes.

Sweet Peas in Tubs.—Many an amateur laments lack of space, but a paved backyard can be converted into a "Sweet Pea garden" for a very small outlay. Get a few lard tubs and, having bored holes in the bottom for a drainage outlet, fill with good soil. Having planted the seedlings, the Simplicitas Circle makes a fine finish, and Sweet Peas thus grown and kept well watered and free from seed-pods will yield a wealth of blossom for many weeks. It will be necessary to give liquid manure fairly frequently when the plants are in full flower, and an almost daily watering with soot-water will keep the foliage in good condition. Sweet Peas in tubs are most effective and quite easily managed. This method of culture should become more popular, as the tubs can be placed in any selected spot and add beauty where all else fails. S. M. CROW.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

CHRISTMAS ROSES (Wrotham).—The Giant Christmas Rose (*Helleborus niger maximus*) is the largest-flowered of its race; the blooms are white, ruddy on the outside, and appear in November. *H. juverna* has smaller and much whiter flowers, which do not open before mid-January. The plant, too, is of dwarfer growth. There are other forms, as major "scoticus" and *Mme. Fourcade*, the whole constituting a set valuable for successional flowering. The better way would be to obtain plants in September next; it is now too late to plant them. Seeds are very slow to vegetate, and often take a couple of years before the plants appear. After that, you may have to wait

half-a-dozen years before the flowering stage is reached. If in August next you will write us again, we will give you the necessary instructions for planting at a seasonable time.

NEGLECTED GARDEN SOIL (Sipho).—If, as you say, "the garden has not been manured or attended to for many years," nothing short of a thorough trenching and manuring are likely to be of the least service. In such circumstances no manure is equal to well-decayed stable manure, which may be dug in liberally at 9 inches to 12 inches deep. You may further improve the fertility of the soil by forking in lime at the rate of one bushel to each rod of ground. That might be done subsequent to the trenching and manuring. Artificial manures are no fitting substitutes for those of an organic nature in such circumstances. They are serviceable, rather, as adjuncts later on. We could only say whether the soil required lightening after seeing it or a sample of it. If heavy, as you say, lime will assist porosity, and double the above quantity might be given for that purpose. Ashes, i.e., coal-ashes, while assisting drainage, not infrequently impoverish the soil, while those from rubbish fires are rich in potash and other salts. It will be best to prune the newly planted Roses rather hard back this year, and in doing so remove all weakly shoots at ground-level. Some of the stronger shoots may flower this year if left, though it is usually at the expense of a better display later on. If the stronger shoots are well ripened, some of these may be retained, pruning them back about eighteen inches. The remainder should be pruned to within six inches of the ground, to encourage good rods for flowering next year. As you confess to "knowing so very little about gardening," we may remind you that we are always willing to render what assistance is in our power.

THE GREENHOUSE.

INFORMATION ABOUT THOMASIA SOLANACEA (Life-long Reader).—Your surmise that the name of the specimen enclosed is *Thomasia solanacea* is quite correct. It is a native of Australia, whence it was introduced in 1803. It has been grown here ever since, but outside of a botanic garden it is rarely met with. The reason of this is that the flowers are not showy enough for general decorative purposes, the standard by which nowadays everything is judged. In Cornwall, and in the milder parts of Ireland, this *Thomasia* will, no doubt, succeed out of doors. Generally speaking, however, it must be regarded as a greenhouse plant. Nearly fifty years ago there were two or three good specimens in the Temperate House at Kew, and no doubt it is still represented there. Cuttings of the half-ripened shoots put into sandy soil in a propagating-case with a gentle heat will root without difficulty. It succeeds well in a mixture of loam, peat and sand.

INCREASING ECHEVERIA METALLICA (Quaker).—You seem to be particularly unfortunate in your attempts to propagate *Echeveria metallica*. It should winter well in the temperature stated by you—45° to 50°—during which time the roots must be kept moderately dry, but not parched up. It is strange that the leaves die after they are rooted without forming a plant at the base. Perhaps you do not strip off the leaves to their full extent. They are best dibbled into sandy soil and placed on a light shelf in the greenhouse or similar position. This is a very suitable time of the year to put in leaf cuttings. Perhaps you did yours in the autumn or winter season. We cannot understand the reason why the old stools do not throw out shoots when the tops are removed. They should be kept almost dry and in a light, sunny spot. There yet remains another mode of increase, and that is, if you can grow on a strong specimen so that it flowers, if it is kept in a sunny greenhouse and the flowers are fertilised with their own pollen, seeds will be produced, and, from these, young plants can be raised in quantity. *Sempervivum tabulaeforme* can be increased by leaves, but not very readily. When old plants are tall enough they may have the tops taken off, and the lower part of the stem will in time break out. Besides this, suckers are sometimes available, and seedlings may also be raised.

TREATMENT OF IMANTOPHYLLUM MINIATUM (Clivia).—We cannot find any disease affecting the leaf of the *Imantophyllum* sent, for the old leaves often go off in the spring just as the flowers and new growth are pushed up. There must, however, be something lacking in the condition of the plants that induced them to flower in an erratic manner last summer. This would fully account for the comparative failure now. We are inclined to think that the roots of the plant are not in a healthy state, and this could be easily determined by turning the plants out of their pots. If our surmise is correct, the main thing is to get the plants well furnished with healthy roots. This may be accomplished by shaking off the old soil and cutting away all unhealthy portions. It is quite possible that the plants may, with advantage, be put into smaller pots. In any case, they must be repotted in a compost made up of loam, lightened by a little peat or leaf-mould and a liberal sprinkling of silver sand. Care must be taken that the pots are well drained with broken crocks. After this, the plants must be carefully watered, especially till the roots take possession of the new soil. Established plants need to be kept moderately moist at all seasons. Of course, more water is required during the summer than in the winter; in fact, at this last-named season, they may be allowed to get fairly dry. Should the roots of your plants prove on examination to be quite satisfactory, we advise you to give them a top-dressing of some suitable compost, and during the summer an occasional stimulant. The plants may be stood outside throughout the summer, but very heavy rains are not beneficial to them.

TREES AND SHRUBS.

ALMONDS NOT FLOWERING (Dr. W. H.).—It is probable that your Almond trees have grown too vigorously and too late in the season to allow of the wood becoming sufficiently ripened to produce flowers. If your soil is naturally deficient in lime, the addition of lime rubble to the soil will do good; but as your trees are growing freely, there is no reason for applying manure. You might open the ground here and there about the roots, and cut through a few of the principal roots. This will cause sturdier, and consequently better ripened, wood.

MISCELLANEOUS.

SMALL WHITE WORMS (Roman).—The little worms sent are known as white worms. They are somewhat similar in structure to the earthworms, but much smaller, and are often destructive to the roots of plants. They may be destroyed by any of the worm-killers, or by giving the lawn a soaking with lime-water.

BULBS FAILING (Dreamer).—Many bulbous plants suffered greatly last season owing to the dry weather that occurred during the months of May to July, and as a consequence they have given very poor results this season. Only one of the bulbs you sent showed damage by any external agent—the *Narcissus*, and that was attacked by bulb mites. The others had either failed to produce roots or root development had been very feeble all through.

STARTING A MARKET GARDEN (S. E.).—A great deal depends on the situation—nearness to a railway station or market—warmth of soil, aspect, and labour available in growing various crops of fruit, vegetables or flowers. Our advice is to ascertain first what is required in the neighbourhood, the means of disposal at various times of the year, and then make your plans accordingly. Until you have satisfied yourself that there is a reasonable prospect of success, we do not advise you to invest capital. The salient point, though, in market gardening is to produce crops, of whatever kind they are, as early as possible. For instance, salads are much in demand early in the spring; so are new Potatoes, early Cabbage, Mushrooms or Green Peas. The same remark applies to Strawberries, Apples, Currants or Grapes; flowers, too, on the same basis.

NAMES OF PLANTS (Beaver).—The flower is *Veltheimia viridiflora*; the leaf is *Monstera deliciosa*.—W. G. Wallace.—*Narcissus cernuus plenus*.—A. Cole.—*Ophrys aranifera*.—*Eriobotrya japonica* (Loquat); *Myoporum laetum*.—W. E. P.—1, *Abutilon Savitzii*; 2, *Spiraea japonica*; 3, *Symphoricarpos orbiculatus*; 4, *Scelopendrium vulgare marginato-cristatum*.

SOCIETIES.

DEVON DAFFODIL AND SPRING FLOWER SOCIETY.

THIS society opened its spring show in the Guildhall, Plymouth, on April 2. It was a successful exhibition, the competition being very keen and the flowering shrubs quite as good as they were at Truro. The prize-list included: Collection of twenty-four varieties of Daffodils, first, Miss Clarice Vivian; group of Daffodil seedlings not yet in commerce, first, Mr. H. G. Hawker; six varieties yellow trumpet, first, Miss Clarice Vivian; six varieties bicolor trumpet, first, Miss Clarice Vivian; collection of nine varieties spring flowers, first, Mrs. Froude—Iris tingitana in this stand was very fine and received cultural commendation; and six varieties spring flowers, first, Mrs. D. M. Yonge.

Flowering Shrubs.—Group of Rhododendrons, first, the Earl of Morley; fifteen varieties of hard-wooded flowering shrubs and climbers, first, Mr. H. W. Grigg, who showed *Osmanthus Delavayi* (first-class certificate), *Prunus spinosa* flore pleno, *Ceanothus rigidus*, *Forsythia suspensa*, *Citrus trifoliata*, *Prostanthera rotundifolia*, *Phillyrea decora*, *Erica australis*, *Illicium religiosum*, *Grevillea sulphurea*, *Prunus persica* flore pleno, *Cerasus sinensis pendula*, *Akebia lobata*, *Clematis balearica*, and *Magnolia soulangeana*. The competition in this class was so close that only four points divided the first, second and third stands. Six varieties hard-wooded plants, first, Mr. T. B. Bolitho, with *Grevillea Preissi* (award of merit), *Clematis indivisa lobata*, *Dendromecon rigidum*, *Eriostemon myoporoides*, *Acacia diffusa*, and *Grevillea ornithopoda*.

Nurserymen's exhibits added materially to the display. The Devon Rosery, Torquay, showed a splendid collection of new Roses, as well as fine plants of such ramblers as Dorothy Perkins, White Dorothy, Excelsa, Aimée Vibert, Edmond Proust, Blush Rambler and Leuchstern. They also showed *Amaryllis*, very fine, the new *Azalea Joseph Vereane*, *Acacia cordata*, *A. armata*, *Lopezia miniata* and new Lilacs. Messrs. R. Veitch and Son, Exeter, showed *Camellia magnoliiflora*, *Cineraria Matador*, *Grevillea longifolia*, *Eriostemon linearifolium*, *E. buxifolium*, *E. neriifolium*, *E. scabra*, *Prostanthera rotundifolia*, *Chorizema Lowii*, *Eutaxia myrtifolia*, *Magnolia soulangeana*, *M. s. nigra*, *M. stellata*, *M. conspicua*, and *M. Lennéi*. Messrs. John Piper and Sons staged *Viola Golden Wave*, *V. gracilis*, *V. Piper's Black*, *V. Dream*, *Veronica diosmefolia*, *Lithospermum Heavenly Blue*, and a large collection of Primulas. Mr. J. C. Martin, Truro, showed an interesting selection of Daffodils, among which were Great Dane, Searchlight, Artificer, Iron Duke and Rockery Gem. Messrs. Barr and Sons gave a fine display of Daffodils, among these being Orangeman, Blazing Star, Furnace, Bloodstone, Argent Venus, Gwendalin, Battleaxe, and Fairy Queen.

THE GARDEN.

No. 2214.—VOL. LXXVIII.

APRIL 25, 1914.

NOTES OF THE WEEK.

The Double-Flowered Sloe.—It is difficult to understand why this charming spring-flowering shrub is so little known. Just now its dark-coloured branches are wreathed with snow white double blossoms, which make a very pretty feature in the landscape. It forms a large shrub or small spreading tree, and is quite as hardy as the Sloe of our hedgerows. Its botanical name is *Prunus spinosa flore pleno*.

Meconopsis Wallichii.—This lovely Poppy, with its attractive foliage, and which produces flowers of the loveliest pale blue imaginable, is somewhat difficult to manage. Sometimes it will stand out of doors during severe weather, while at other times it seems to go off rather mysteriously. In the North the plants had better be kept in a cold frame during the winter, and those that have to be treated may be planted out now. Those who experience difficulty in getting the plants to ripen the seed sufficiently early would do well to pot on one or two plants and flower them in a cool greenhouse. The same remarks apply to the beautiful *M. integrifolia*.

A Beautiful Prunus (*P. acidumosa*).—This exceedingly pretty tree belongs to the Cherry family, and, like all other members of the group, it is referred to under the name of *Cerasus*. In Japan cherry blossom time is marked by national rejoicing, while in this country the flowering of the Cherry, including innumerable varieties, is looked upon as the most delightful of all seasons in the garden or countryside. *P. acidumosa* is a variety of a European species which flowers profusely even at an early age. Flowering as it does without attaining great dimensions, it is a very desirable tree even in a small garden. This variety is not widely known, but it resembles All Saints' Cherry (*P. acidumosa semperflorens*), to which it is closely related.

The Rose Annual.—On another page we publish some particulars of the Rose Annual, the official organ of the National Rose Society. We have no hesitation in describing this as the best the society has ever published, and the thanks of all rosarians are due to the Council and the hon. secretary, who has acted as editor,

for their efforts. The Rose Annual for 1914 is an interesting, varied and practical symposium on Roses, and we hope all our readers will secure and read it. That way lies the advancement of the Rose.

A Useful Dwarf Shrub.—*Pyrus Maulei* is a valuable hardy, low-growing shrub, and flowers most profusely. It naturally assumes a neat, bushy habit, and is at the present time covered with its bright red flowers, which completely hide the plant. These are followed later by large

grouped in large masses between huge sandstone boulders, and the first named was a perfect sheet of violet blue flowers. Fire King, though not so free with its blossoms, was, however, a charming sight, the warm red flowers showing to perfection when kissed by the afternoon sun. Both ought to be grown in every rock garden where spring flowers are appreciated.

A Charming Golden-Leaved Plant.—Another *Aubrietia* that Sir Frank Crisp grows so well on his rock garden at Friar Park is *A. aurea*. Although we do not care for most plants with variegated foliage, an exception must be made in this instance. It would, perhaps, be more correct to speak of it as a golden-leaved plant, though some of the foliage is undoubtedly variegated. However, the main colouring is soft golden yellow, and as the flowers are pale mauve, the combination of colours is exceedingly charming. Undoubtedly its attractiveness is enhanced by the massing of the plants in one large group, instead of scattering them about as isolated specimens, as is too often done.

Spring Flowers at Hampton Court.—The beds and borders of spring flowers at Hampton Court are now flowering to perfection. In the long border, Wallflowers Harbinger, Primrose Dame, and Ruby Gem, the latter of a purple hue, are all beautifully arranged with a profusion of Polyanthus and spring bulbs. Hyacinth Cardinal Wiseman (pink) and Tulips Keizerskroon, Cottage Maid and Duchess de Parma are flowering magnificently. The following make very attractive beds: Tulip Rose d'Amour and Hyacinth Grand Blanche over a groundwork of the purple *Aubrietia* Dr. Mules; Wallflower Fairy Queen and Tulip

Fred Moore. What is perhaps the prettiest bed of all is composed of *Narcissus* Mrs. Langtry, Hyacinth Yellow Hammer and Tulip clusiana, otherwise known as the Lady Tulip. Other good beds are *Narcissus* Mme. de Graaff, Tulip Murillo, with *Aubrietia* Dr. Mules; and Tulips Yellow Prince and Joost van Vondel (white) with purple *Aubrietia*. *Narcissus* Queen of Spain with Saxifrage Red Admiral make a pleasing display when grown together.

A WELL-FLOWERED TREE OF PRUNUS ACIDUMOSA.

ruddy-cheeked fruits, which form a conspicuous feature in autumn. Being from 1 foot to 2 feet high, it makes a very attractive edging to taller shrubs, or it may be planted on the bolder parts of the rock garden with telling effect.

Two Beautiful Aubrietias.—When visiting the famous rock gardens at Friar Park, Henley-on-Thames, on Friday last, we were pleased to find *Aubrietias* Mrs. Lloyd-Edwards and Fire King growing to perfection. Both were artistically

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Large Narcissus Fly.—I should be greatly obliged to any of your readers who, digging up failing Narcissus bulbs at this season and finding the larvæ of the large Narcissus fly in them, would send examples to me.—F. J. CHITTENDEN, *The Laboratory, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey.*

Daffodils with Lasting Qualities.—I should very much like to know if any of your readers find any difference in the lasting qualities of Daffodils in bloom. This year I grew (in soil) bulbs of Victoria in a box and Mme. van Plomp in flower-pots. The latter were admirable, and the flowers kept in splendid condition much longer than the former. My accommodation for bulb-growing is extremely limited (one window), so that space is begrudged to bulbs that are quickly over; and a "wait and see" policy could be dispensed with if some of the readers of THE GARDEN would enlighten me as to which Daffodils and Tulips are the "best lasters." In Tulips I found White Pottebakker continued to bloom longer than Grace Darling. Three pots of Prince of Austria are superb. There can be nothing better in Tulips. Colour, carriage, and a delicate Primrose scent are some of their charms. An amateur naturally wishes to try something new every year, and a guide as to lasting qualities would be invaluable.—M. E. E.

Dahlia imperialis on the Riviera.—I was very much interested by your notes on this most famous plant in THE GARDEN for December 20, 1913. It certainly is very much admired by all in this part of the Riviera. I am sending you a photograph of a very fine specimen grown in the garden of Miss Kay-Shuttleworth. It is over fourteen feet high, and shoots forth from the ground in May and grows rapidly until flowering-time in November. It needs a stiff loamy soil, copious supplies of water, and plenty of manure, and will do well facing due south, protected on the north-east against cutting cold winds.—GEORGE PARISH, *Chalet Ponente, San Remo, Italy.* [Unfortunately, the photograph sent by our correspondent was not suitable for reproduction; it showed a very fine plant.—ED.]

Sparrows and Spring Flowers.—Re the notes which have appeared dealing with this subject in THE GARDEN under dates March 7 and 21, also April 11, I venture to draw the attention of the writers of those notes to an article in the *Country-side*, "Sparrows and Crocuses," by Mr. E. Kay Robinson, the well-known naturalist. Mr. Robinson says a careful examination seems to show that the birds are after the stamens of the Crocus, the anthers of which have some nutritive value, while the juicy tissues of some flowers and stems may be pleasant to eat also. Coming from such a careful investigator and acknowledged authority, I think these conclusions are weighty, and should be recorded for the benefit of all readers of THE GARDEN. This season, for the first time with us, the sparrows have bitten off several heads of Muscari Heavenly Blue, leaving them near by. Also the just opening flowers of a double mauve Primrose recently put in the rockery were nipped off and left beside the plant, while last year they disfigured several Polyanthus spikes before we noticed them—both colours, but chiefly the yellow shades. How they mutilate the quite young

leaves of the border Carnation when they push forth in early spring is well known. Apparently here it must be the juicy tissues that are the attraction. In each and every case the best deterrent so far known is a few strands of black cotton.—C. T., *Highgate.*

Established Bulbs of Chionodoxa.—In regard to your note on page 178 of April 11 issue, I cannot agree with Mr. Negus about Chionodoxa sardensis being at its best in its first season. I have grown it and C. Luciliae for ten years here, and each year they have increased in growth and produce better flowers than when first planted.—B. C. SYKES, *Borrobol, Kinbrace, Sutherland, N.B.*

—My experience with Chionodoxas agrees with yours. No newly planted bulbs, be they ever so fine, give such good results as established bulbs. With these the flowers are individually larger, and are much more numerous on the spikes. I find that they do best when planted rather deeply, not less than 6 inches. Self-sown seedlings eventually descend to that depth, and frequently deeper. The soil here is stiff loam on clay.—A. D. FORT, *Steepleholme, Slades Hill, Enfield.*

—I am at one with Mr. Negus in my dislike of loose colour descriptions, and often wish that there was some generally recognised standard of nomenclature, but I cannot understand why he objects to the term "Gentian blue" as applied to the tint of Chionodoxa sardensis. Perhaps he will tell us what he calls it, or how he would define it. To me it seems very appropriate. Again, with regard to newly planted bulbs being equal in vigour and floriferousness to those well established, I may say that I have bought a large number from both English and foreign sources for the last twenty years, and my experience is that it is only on those rare occasions which prove the rule that Chionodoxas, when they flower for the first time after being planted, are equal to those old-established plants which give me good, sturdy spikes of 9 inches to 12 inches in length, bearing anything between ten and sixteen blooms. Perhaps Mr. Negus is only thinking of what he bought last autumn when he says, "I have a few hundreds, planted last autumn, which are vastly superior in flower to my established clumps." It is rather curious that my bulbs, which were newly planted last autumn, have flowered this spring with altogether exceptional vigour; but this is not the rule.—JOSEPH JACOB.

The Improvement of Garden Roses.—There is much to be said in favour of the improvement of what are termed "garden Roses," but to do this there are many obstacles in the way. First, how are garden Roses to be defined? Some of the finest exhibition varieties are also excellent sorts for the garden. Take Gloire de Chedane Guinoisseau, one of the best of exhibition sorts, and certainly most valuable in the garden. The growth is vigorous, compact, and the freely produced blooms upon an ordinary bush plant are certainly decorative and suitable for any garden. Take, again, Dr. Grill as a bush or a standard. No Rose in the garden is more appreciated for cutting for the house, and no Rose of less value for the exhibitor. Take, again, Mrs. Edward Powell, a newer type, remarkable for its rich colouring, robust growth, freedom and continuity of flowering right into October. As a garden Rose none is more appreciated. It is most difficult to define a garden Rose apart from an exhibition variety. I think we shall find Mme. Edouard Herriot one of the best of garden

Roses, but doubtful as an exhibition variety. I really do not think much fault can be found with the awards of the National Rose Society, when we consider what a large number of sorts are yearly placed before the committee. Those gaining an honourable distinction in the past have as a whole fully borne out the justice of the award. What I think is carried to excess is the enormous number of new varieties sent out yearly, especially by some firms. So many are nearly alike that we do not require all that are put upon the market; but how is the amateur to discriminate when nothing but a catalogue description to guide him is available? Some suggest a national trial garden for all new varieties. That scheme is not likely to come to pass; it is much too slow for the present day. If a promising new variety is introduced, the amateur wants it at once, as there is so much charm in watching the development of new sorts with a high reputation. I think if nurserymen would send out fewer new sorts annually, giving them a further test, the public would have more confidence and be inclined to purchase more freely. Personally, I do not think very drastic steps are needed in the method of recognising desirable new varieties of garden Roses.—E. M.

—A discussion of this subject is certain to appeal to a very wide circle of your readers, and it is to be hoped that some valuable suggestions may result. Though keen amateur rosarians may by "elimination of undesirables get what they want," it seems to me that this method, involving as it does expense, waste of time and disappointment, has little to be said in its favour, particularly in the case of those enthusiasts whose means and space are limited. Your correspondent Mr. Taylor points out on page 171 issue April 4 that the system under which awards for show Roses are granted is useless applied to garden or decorative Roses, and it is here, I think, that a strong appeal should be made to our National Rose Society to formulate some scheme for "hall-marking" such of the new Roses found to excel in those desirable qualities enumerated by "White Rose." Form and colour are details quite readily picked up at the shows; but three points to which I attach special importance, viz., freedom of bloom, behaviour as a cut-back, and healthiness of foliage, can only be correctly judged by extended trial. To take a case in point. That very beautiful Rose Queen Mary, Mr. H. E. Molyneux, whose criticisms of the newer Roses are so highly appreciated, appears to have fallen a willing victim to its charms, and yet, judging solely by the plants on view when it was awarded the gold medal last July, neither its growth nor its beauty of foliage appears to be a marked feature of merit. (Mr. Molyneux does not refer to either point in his appreciation.) There are, I am sure, many rosarians who prefer to see their Roses in the garden, and it is there that healthy, ample and handsome foliage is absolutely essential to bring out the fullest beauty of the bloom. Those varieties subject to defoliation, mildew, &c., cannot be considered good garden Roses. I venture to suggest that if a distinctive award for decorative Roses only could be instituted—the points to be taken into account being form, colour, fragrance, growth and freedom as a cut-back, quality and amplitude of foliage—such an award would stamp a Rose as of outstanding merit for garden purposes, and be accepted by amateur rosarians with implicit confidence.—H. STEVENETTE, *Wanstead, N.E.*

Camellia reticulata Flowering Outdoors.—Of your readers may like to know that after four years from planting I picked on Good Friday some lovely blooms of *Camellia reticulata* grown in the open ground in peat soil, and with no covering during the winter.—ALFRED C. LEVER, *Saltwood, Kent.*

Preserving Stone.—On page 188 of your issue of April 11 I notice under "Answers to Correspondents" a reply to "E. F. O." The Bath stone firms of Bath sell a chemical called (I believe) Fluuate, which has the virtue of hardening all kinds of stone, and this will probably supply your correspondent's need. I so much enjoy THE GARDEN that I shall be glad if this information is of any use to you.—PERCY C. WEBB.

Coronilla glauca Growing Outdoors.—It may not be generally known that the old sweet-scented *Coronilla glauca* that is grown in the greenhouse will thrive and do better planted out in the garden in a warm situation. I was looking round a garden the other day, and saw two plants of *C. glauca* growing on a warm south border. The gardener told me he planted them out about two years ago. They certainly looked the picture of health, and appeared to enjoy their open position. I noticed the plants were smothered with the pretty yellow, fragrant flowers, and the bees were busy about them. I thought what a contrast to the starved condition we often see them in the greenhouse.—W. DRIVER, *Stonehouse.* This plant does well outdoors in many districts.—ED.]

Cold Storage for Roses.—Regarding this, "Danecroft," on page 167, issue April 4, is hardly correct in stating that American florists cold store Roses. All the United States florists have ice-boxes—really, large glass-sided coolers—for keeping flowers during the hot weather; but actual cold storing for an indefinite period is not possible. Prior to certain flower days, of which there are many in America, some growers and wholesale florists do hold up part of their supply for two or three days; but these "pickled" Roses and Carnations arouse great hostility. Retailers who get hold of such stock quickly discover the fact, for the blooms soon collapse when exposed to the ordinary temperature. I venture to hazard that chilled Roses would soon be asleep if staged at a summer show.—C. A. W.

How to Trap Slugs.—I am sure everyone with a garden where the soil is heavy is plagued with slugs this year, and just at present they are increasing very rapidly. I have tried Orange Peel, patent traps, slices of Turnip, and Cabbage leaves. All are good, but cover far too small an area. I have now begun on a large scale to trap them by means of an old wet sack thrown on to the seed-bed at night, and either bran or a little flour sprinkled under it. Every kind of error from the soil is revealed in the morning. Wireworms hurry down their holes, woodlice curl into balls ready to be caught, and slugs and snails lie on the sack, and can be shaken out

in the chicken run.—ETHEL CASE, *Bishop's Waltham Chase.*

A Beautiful Hardy Plant.—To those who intend adding to their list of hardy plants, I should like to mention *Oenothera Arendsii*, a lovely subject for the rockery or border. We grew it last year for the first time. It proved a most useful and continuous plant to flower from June to October, with pretty rose pink flowers. It can be easily propagated from cuttings, and it came through this winter without protection. It prefers a warm, sunny border.

A NEW VARIETY OF THE PURPLE-LEAVED PLUM, *PRUNUS PISSARDII BLIRIEANA FLORE PLENO.*

I am of the opinion that it would be very useful as a pot plant.—M. NICHOLLS, *Kemsing, Kent.*

FORTHCOMING EVENTS.

April 29.—National Auricula and Primula Society's (Midland Section) Show at Birmingham (two days). Perpetual Flowering Carnation Society's Spring Show at Bournemouth (two days). Royal Caledonian Horticultural Society's Spring Show (two days).

April 30.—Manchester and North of England Orchid Society's Meeting.

May 2. Société Française d'Horticulture de Londres Meeting.

ROSE-GROWING IN TOWN GARDENS.

SOME NOTES ON ARRANGEMENT.

NEATNESS and order in a garden denote the careful cultivator, who will keep his plants clean and give them every opportunity to do well. But the benefits obtained from the exercise of taste in arrangement are beyond anything that mere tidiness can secure.

Some amateur Rose-growers, whose chief hobby is the exhibition of their blooms, like to model their gardens upon the same lines as the nurserymen. The latter find it convenient to marshal their plants in formal rows; but the amateur is planting for permanent effect, and surely it is best to make the appearance of the garden worthy of its productions.

In a small garden the ideal is naturally harder to attain, and it requires a certain amount of ingenuity to overcome the primness that is inevitable if one follows out the straight lines of the boundary in the design. Paths need not invariably be straight, beds may be fashioned into shapes that will help to avoid stiffness, and arches, pergolas or screens can be so placed as to secure effect without obstructing the outlook or apparently diminishing the size of the garden. These are points which need to be considered separately in relation to each individual case, and an arrangement that appeals to one may merely irritate another, so that it is well for each individual to be the surveyor of his own domain. The most natural and effective setting for Rose-beds is a lawn. Grass walks between give the beds a better finish, though they involve a certain amount of extra work in cutting and edging. Moreover, the beds should be sunk slightly below the surrounding level, and this is more easily effected in a lawn than elsewhere.

Colour schemes are well enough in a large and well-ordered establishment, but the town gardener usually finds them outside the range of practicability. Nevertheless, it is possible to avoid glaring errors of taste. It is with the red Roses that most care is needed, as it is in these that the clashing of colours mostly occurs. Scarlet tints, as in Captain Hayward, are perhaps the most difficult for which to find suitable companions, and they should never be placed close to crimson or deep rose pink shades. Salmon pink and rose pink varieties

should also be kept separate. Even in the lighter colours each kind needs to harmonise with its neighbour if it is to appear at its best.

To be able to identify all the trees readily is an obvious necessity, and labels have many drawbacks. They are always more or less unsightly. If fastened to the trees, they are apt to damage the growths; if placed in the ground, to get in the way of the hoe. The most satisfactory method is to make a rough plan of each bed, marking the names of the Roses as they are planted. Keen gardeners will find such plans add considerably to the joys of anticipation before their blooms appear. A rough sketch can be made very

quickly, but many will like to elaborate it at leisure.

Care is needed in placing screens, pergolas or other long and lofty arrangements, which frequently make a small garden look still more diminutive. A pergola should lead from one part of a garden to another; but it may also be made to form the entrance to the garden, and this is often the most convenient place for it where the latter is of small extent. It should not be placed across a short garden or down the centre of a narrow one. Sometimes it is difficult to know where to plant the climbing Roses so that they show to the best advantage. Pillars are always effective, are easily constructed, and do not take up too much room. They might often be made of more use. A row of these along the back (*i.e.*, the north or west side) of the Rose-beds will always be admired, and so placed they will not be depriving the other Roses of sunshine.

P. L. GODDARD.

COLOURED PLATE.

PLATE 1492.

ROSE RED-LETTER DAY.

THE beautiful decorative Hybrid Tea group will be immensely strengthened by the addition of this brilliant Rose. I shall not soon

forget the fine colour effect produced by a mass of Red-letter Day upon my visit to Newtownards last July. What a colour, and what a grower! It seemed to tower above every other Rose as far as effective display was concerned. The flowers are semi-double, and its velvety, brilliant scarlet crimson buds and fully opened Cactus-like petals never fade, as the reflex of the petals is satiny crimson scarlet, absolutely free from blue or magenta. This is a great gain, for everyone knows the bluish tint of the expanded flowers of such as Marquise de Salisbury is a great fault from a decorative point of view. There is a specially refined growth with Red-letter Day, and, as I said, it is splendidly vigorous. Moreover, it is festooned with bloom the whole of the flowering season. I can foresee the day when this beautiful novelty will

be massed in huge quantities, for it is just the Rose we have been waiting for. Those who have had to make Rose gardens know only too well the difficulty of supplying good, brilliant colours to compare with the paler and golden shades, and I fear many have resorted to the old Hybrid Perpetuals because of their splendid colours, only to throw them out for their lack of decorative effect. Messrs. A. Dickson and Sons seem to have produced a most wondrous strain of free-flowering decorative Roses of brilliant colouring, for I saw many others that were being worked up, and I feel sure the reproach

that used to be thrown at the Hybrid Teas for the paucity of crimson and scarlet varieties will soon be removed, especially when we have other raisers also working on these lines. Messrs. Hugh Dickson's Brilliant will also be a fine triumph of colour. A mass of it at Belmont last July was as effective as a bed of Geranium Paul Crampel.

It is a great advance to obtain Roses such as Red-letter Day, which combine vigour of growth with a free-blooming habit. There are many Roses free in growth, and in some respects too free, but they do not yield a corresponding amount of bloom. One cannot well use such Roses as

CLEMATIS ARMANDII, A NEW HARDY SPECIES FROM CHINA. THE FLOWERS ARE WHITE.

Hugh Dickson or J. B. Clark as bedders, and Grüss an Teplitz is most embarrassing in its growth, so that all who have had this difficulty to contend with will doubly welcome Red-letter Day.

The gardening profession knows no politics, but I am sure all readers will desire that by the time Red-letter Day is introduced in June, its advent may witness a real red-letter day in Ulster, its home, in that peace with honour will be acclaimed by all parties in that lovely portion of a very beautiful country.

DANECROFT.

TWO NEW HARD-WOODED PLANTS.

An Exquisite Semi-Double Prunus.—As described in our last issue under "New and Rare Plants," page 196, *Prunus Pissardii blirieana* flore pleno is a very beautiful plant, and quite distinct from the double form of the type. The branches are long and slender, with purple-tinted leafage, while the flowers are of a warm apple blossom pink and semi-double. It is a charming variety, valuable both for the decoration of tables and vases, and for garden effect in early spring.

Clematis Armandii.—The exceptionally high award of a first-class certificate was recently bestowed upon this Clematis by the Royal Horticultural Society. It is a hardy and very free-flowering climber of strong growth. A description of this Chinese species appeared in our last issue, page 196. The pure white flowers are borne in axillary clusters early in the season. As this species combines hardiness with other good qualities, it is a great acquisition to the genus, and will certainly be widely grown in the near future. The plant illustrated was shown by the Hon. Vicary Gibbs, Aldenham House, Elstree, Herts.

YELLOW GLADIOLI.

OF the newest kinds of Gladioli, the yellows are, perhaps, most attractive, and though their prices are as yet a trifle high, they are well worthy of a place in every collection. Of lemon colours I found Niagara most dainty and charming, but it is easily affected by the acid, sooty nature of our atmosphere (near Glasgow). Canary Bird I grow also, but last season it did not succeed well for some unaccountable reason, although I had previously found it a very fine variety. Glory of Noordwijk is a magnificent flower, and of the first order as an exhibition bloom. The tint is a distinct chrome yellow that shows up well in a group and stands clear for a longtime. I have no hesitation in placing it first among all the yellow varieties. Golden Measure, one of Messrs. Kelway's introductions, is a good second in the class of ordinary

yellows, and as it is easier and cheaper to obtain, it may be more generally grown. It makes a fine spike for an exhibition group, and stands out prominently in a harmonious blending of tints on account of its purity and brightness. Yellow Beauty and Golden Girl are both stately and distinct yellow varieties. They succeed very well in Northern gardens. Of deep yellows with a decided orange tint there are two, Golden West and Sunset, both without rival in this class. Enthusiasts will find the above varieties among the very choicest and most charming kinds.

CRAIGIELEA

REASONABLE NOTES ON WATER AND WATER-SIDE PLANTS.

Thinning Out Dense Growth. The season is now be said to have fairly arrived when proceedings may be taken either to renew and replenish or to thin out such as are growing too luxuriantly. There is a considerable degree of tendency in the latter direction with such of the stronger-growing and other robust growers from among the many aquatic plants. These, if not occasionally thinned out, will exceed all reasonable bounds. In doing this the flowers of many *Nymphaeas* are really not seen at all, these being hidden under a mass of foliage; such, for instance, as *N. arifolia*, *N. M. rosea*, *N. M. albida*, *N. Collesia* and *N. Moorei*. These are all vigorous growers, and often push up a dense mass of foliage well above the water level. In rearranging such as these I have often pushed them out into deeper water, where they have done well. As much as 6 feet of water over them is none too much where they are living well.

All that one has to do just now is, first, to secure one or two pairs of waterproof waders, such as fishermen use in salmon and other rod fishing. Equipped with these, one can wade to a depth of 3 feet 6 inches of water safely enough, if needs be. It is advisable to lower the water, however, to a foot or so of the crowns when, with a good spade first to cut or divide the plants, and then one or two digging forks by which to lift them out of the mud, it is easy to secure strong divisions. These, as soon as possible, should be placed into ordinary nursery rounds, such as those seen in one of the illustrations; there is nothing better than these for re-establishing the plants after division. Secure baskets that are large enough for the purpose. Then place a layer of last season's leaves at the bottom, and upon that some good turfy loam and road dirt or river sand. On this place the lifted plants, with the crowns in all probability above the level of the top of the basket; then fill in all the interstices with the same kind of soil, making it all fairly firm. It will then be necessary to pass over some stout tarred string to keep the plant in position, otherwise a plant will float away of its own accord after being replaced in the water. By so doing, it then will be secure until the roots once more establish themselves in the mud. When baskets are not available, the divisions may be placed where they are to remain, being either pegged down or otherwise weighted down to prevent them from floating, some good soil being used as in the baskets. The baskets, I might add, can be pulled out into deeper water by passing a cord through the handles of the baskets and thus pulling them to their position; then the cord can be slipped out if it is double. In this way it is an easy matter to place them in 6 feet of water.

Some to be Let Alone.—When a plant is divided and not overcrowded, by all means let it alone. Of course, if the water is allowed to

attend to the larger and denser masses, it is just as well to place some good soil around these. Perhaps also a crown may be seen to be extending over the sides of a basket that was put in at some previous time. In such a case cut away the basket and pack up soil to attract fresh root action outside. Personally, I prefer old rather than new nursery rounds; these latter will often last sound too long for the real good of the plants.

Other Water Plants.—It will be noted in the illustration, to which I have already referred, that the water-side plants that grow in the shallow portion next to the edge are cut down. This is as it should be at this season of the year. It will now soon be a dense mass of growth again. Some such plants as *Typha latifolia*, *Glyceria aquatica* and *Acorus Calamus*—often grow much too freely and become too dense. Now is the time to thin these down with an unsparing hand. Many of the smaller-growing aquatic or sub-

mers thrive well. What we have done is to raise the soil in the water sufficiently high to plant them in this way: first, by placing brick rubble in the water up to its level, then filling in with some clinkers and ashes so that one can walk upon it without getting wet. Upon this the soil is placed and the plants put in straight away. *Senecio Clivorum* does well in the same position, so also do the *Gunneras*. By this method it is obvious that the roots percolate to the water and thus sustain themselves. To prevent the soil immediately in contact with the water from being washed away, it is well to place some rough pieces of tufted grass next to the edge. The effect of such groups as these when backed up by *Bamboos* is most pleasing and appropriate.

Some Other Aspects. Water gardening, when carried out in a judicious manner and with due regard to the surroundings, is most effective—such as that, for instance, in the larger illustration

WELL-GROWN SEEDLING WATER LILY.

aquatic plants require attention almost every spring to keep them as they should be. *Myosotis palustris* always, to my way of thinking, thrives better the first season after transplanting. *Butomus umbellatus* may remain for two or three years; then it will get too thick. *Caltha palustris* should be divided every other season. It is now just coming into flower with us. It ought to be much more extensively grown than it is, being very showy and lasting in flower for such a length of time. *Trollius europæus* is now in flower. If it needs division, wait until the flowering is over. *Aponogeton distachyon* may be transplanted at almost any season. It grows so freely and soon becomes re-established.

Other Water-side Plants.—Of these there are several most useful and highly ornamental subjects; for instance, the newer hybrid *Astilbes*, such as *A. Ceres*, *A. Venus*, *A. rubella* and *A. grandis*. If the soil in which these are planted is 6 inches to 1 foot above the water level, they

that accompanies this article. In the season the effect would be very fine; infinitely better, in my opinion, than any set design of flower beds. Here it will be also noted that the process of thinning out has been carried on, and by the use of the boat. One or two clumps in the foreground are showing indications of thinning out being required. In the illustration on this page an individual plant is depicted in good condition. This might require some such attention in a year or two. By the numerous letters of enquiry respecting Water Lilies that reach me from time to time, I find that many still continue to use wooden tubs for their cultivation. Nothing, in my opinion, is more irrational than this practice. It inevitably follows that the soil within these tubs becomes in time in a filthy, stinking condition, totally unfit for *Nymphaeas*, mud-lovers though they be. My advice is to never use tubs on any account. By this I mean a tub that is sunk under the water for aquatic plants. Neither do I, in the

THE BASKETS SHOWN ABOVE CONTAIN WATER LILIES AND ARE PLACED IN POSITION FOR PLANTING.

construction of rockwork, advise that pockets be prepared for water plants; these are equally as bad. If baskets are not used, the next best thing is to use loose bricks to keep the soil in its place.

New Water Lilies.—Of these there are a few most promising varieties that will be distributed this season. These are *N. Neptune*, of which the growth is described as being moderate, with flowers from 6 inches to 7 inches in diameter, and in colour white shaded with rose; *N. Gonnère*, best described as an improvement upon *N. tuberosa Richardsonii*, the colour white with the outer sepals shaded with green; and *N. René Gérard*, evidently one of the most robust growers and with flowers some 9 inches in diameter—the colour is given as bright rosy crimson. Of those first sent out last year, the best are *N. Fabiola*, pink and white; and *N. Gloire du Temple-sur-Lot*, which is a grand novelty, with a great multiplicity of petals, as many as 100 such having been counted. Two others are *N. Picciola* and *N. Sirius*.

JAMES HUDSON, V.M.H.

Gunnersbury House, Acton, W.

THE ENEMIES OF THE NARCISSUS.

(Continued from page 192.)

The Well-Known Narcissus Fly (*Merodon equestris*).—About this little new has to be said. The weight of authority seems to show that the initial point of attack, wherever the eggs may chance to be deposited, is at the base of the bulbs, and there the grubs in their earliest stage must be looked for. How very easily the grub in this stage may be overlooked is evidenced by the fact that, some years ago, the, I think, leading authority upon the subject, Mr.

P. D. Williams, sent to the Rev. W. Wilks twelve bulbs of *Narcissi* for examination; but the presence of the grub was not recognised. However, the bulbs were planted in pots, and, later on, were produced to the Narcissus committee of the Royal Horticultural Society, when no fewer than eleven out of the twelve were found to contain the larvæ of the *Merodon equestris*. Mr. Williams has demonstrated that the earliest presence of the larva can sometimes only be detected by the presence, at the base of the bulb, of "a tiny hole no larger than the head of a small pin." Professor Ritzema Bos has stated that soaking the bulbs in water before planting, for one, or, better, two days, will destroy most of the grubs, and, although this is disputed by some, it should be tried, as it does not injure the bulbs. I mean to submit all future new purchases, of expensive bulbs especially, to a season's quarantine away from the main bulb borders; and we are being driven to the conclusion that yearly lifting and replanting has become an actual necessity. Now we come to another, and perhaps the most serious, as it is the most insidious, enemy which afflicts the Narcissus, namely, the parasitic fungus known as

***Fusarium bulbigenum*.**—Little known in this country until the last few years, although it has existed in Holland for some considerable time, this fungus has assumed such proportions that, according to the statement of growers on a large scale, "entire plots of bulbs have been destroyed." This fungus is propagated by spores cast into the air, and also by mycelium in the ground. One does not want to be unduly alarmist, but, when such evidences of widespread destruction are brought before us by authority, it is clear that growers of the Narcissus must be on their guard. All available information as to this pest can be found in the *Kew Bulletin*, No. 8, 1913,

reprinted in *THE GARDEN*, December 6, 1913.

Other Enemies.—I must not lengthen this article by more than referring to the other enemies of the Narcissus—the swift moth (*Hepialus lupinus*), as to which see Mr. H. R. Darlington's able article in the Royal Horticultural Society's *Journal*, November, 1909; basal rot, if indeed it be, in fact, a specific disease, and not merely the outcome of other causes; yellow stripe, rust, eelworm, slugs, &c. A good deal might usefully be said about each of these, and, looking at the status which the Narcissus has achieved in the world of horticulture, and to the immense number of people now interested in the matter, the "Enemies of the Narcissus" would seem to be a fitting subject for a full consideration in the coming Royal Horticultural Society's "Daffodil Year Book" for 1914. Nothing could be more useful. Perhaps the editor, the Rev. J. Jacob, will give this his consideration.

Foot's Cray. CHARLES E. SHEA.

DAFFODIL NOTES.

VINCENT SQUARE,
APRIL 7.

DAFFADOWNDILLY was in town.

Here, there and everywhere, all over the hall, I kept meeting her. She regularly seemed to dominate the show. There were certainly twelve large groups, without counting small oddments scattered up and down in composite collections. I have no fewer than seventeen varieties down in my notes as having been brought before the Narcissus committee, and I am not sure that I have not omitted one or two of the unfortunates who were "passed," which is the usual official formula uttered by the chairman to signify unsuccessful candidature for honours. Seedlings, especially yellow trumpets, naturally were a very conspicuous feature; in fact, I think they were a little overdone. After all, the general gardener wants something where-with he can ornament his garden, and a single bulb or a small stock of four or five, let us say, does not go far—except, more than likely, in depleting his purse, for such luxuries are like the first plovers' eggs on the market, decidedly expensive. Hence I welcome such an exhibit as that of Suttons, which displayed in an attractive manner many of the more ordinary varieties which we specialists are apt to ignore and forget. Those who more or less come under the category are relatively only a small number, and it is among these alone that there is any considerable demand for the higher-priced novelties.

If I appear somewhat to discount what I have just said by now writing mainly from a show point of view, it is only because I consider catalogue time a more convenient and useful one for discussing the merits and demerits of "stock" kinds. I am writing these notes at the home of Mr. W. F. M. Copeland at Shirley, which is a suburb of Southampton, and where a very cursory trot round a large, old-fashioned garden soon showed me that he is as keen on seedling-raising here as he was at his old home near Stone, and

that we are about to have Shirley Daffodils as we already have Shirley Poppies. I wish all his great range of doubles—Vulcan, Gollywog, Rags and Tatters, Whirligig, &c.—had been raised here; “Shirley Doubles” would have been so handy and euphonious a title.

Royal Sovereign, which gained an award of merit, is one of his latest productions. It is of medium size and loosely built, after the style of Argent. The perianth is white, and the pale lemon corona is not so divided or spread about as is usual. It gives the idea of a lot of short bits punched, and then opened out at the top and caught together at the bottom. It is a cross between Minnie Hume and Telamonius plenus.

Tintoretto, another new double, with deep primrose and orange red colouring, was among those which kept it company on Messrs. Cartwright and Goodwin's stand. It is another even more loosely built bloom, with many bits of primrose perianth in evidence round and among the red-edged, deep orange, broad and boldly split corona. As I journeyed down here in the train, I thought of all the wealth of flowers that had passed under my review during the day, and tried to single out the best. When the time came for gathering up our belongings, I had come to the conclusion that Crystalline, Florist's Favourite, White Maximus, Vauban, The Marquis, Maid of Honour, Vacuna and (to include an older one) Midas were certainly not to be omitted; so perhaps I had better, without more ado, proceed to describe them.

Crystalline (R. H. Bath) is a pure white Leedsii of the long, rather narrow segmented type, with a delicate-looking cup of narrow diameter, fringed or fluted at the top in such a way that I was reminded of The Fawn. It is not very often that I see a flower that I like so

much, and I do not wonder that the tiny stock is to be “grown on” before any bulbs sold out to the public. Dimensions, *à la* Sydenham: $3\frac{7}{8}$ inches \times ($1\frac{1}{8}$ inches \times $1\frac{1}{8}$ inches) \times ($1\frac{1}{2}$ inches \times seven-eighths of an inch).

Florist's Favourite, a transfer from Dinton, was on Mr. Bourne's stand, and although it was surrounded on its circular dais by such beauties as Queen of Hearts, Bernardino and The Earl (yellow Ajax), it seemed to stand there like a king among them, ready to receive the homage of delighted florists. It is a rich deep yellow bloom, with a stiff, flat, widely segmented perianth, which is set at right angles to the trumpet, which in turn is short, wide and nicely recurved at the brim. It is well named, for it is a very “floristy” flower, and is bound to be a favourite among the show fraternity. Size: $4\frac{1}{4}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{3}{8}$ inches) \times ($1\frac{1}{2}$ inches \times 2 inches).

White Maximus (W. T. Ware) features in its general appearance its well-known namesake, although if each part were to be taken separately and compared, there would be found many differences in detail. It is a loosely built, large and long stalked pale bicolor trumpet. Although of ample width, the segments are long and pointed, with a graceful twist in three of them. The trumpet looks longer than it really is, owing, I think, partly to it not being over wide in diameter and partly to the arrangement of the petals, which allows one to see its whole length so clearly and easily. Size: $4\frac{3}{4}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{7}{8}$ inches) \times ($1\frac{1}{4}$ inches \times 2 inches).

Vauban (Wilson) is an exceedingly fine, handsome, deep yellow giant incomparabilis, raised by the exhibitor himself. The large, somewhat straight-looking cup is a decided orange yellow, and is distinguished by the wide scalloping of its brim. The broad, stiff petals are a little turned in

at their very edge. This is a feature which seems to be “coming along,” but which, just at present, is uncommon. It is a totally different thing from the incurving that we know so well in old Frank Miles or The Doctor, being confined to the very edge, like we see it in many Darwin and florist Tulips. Measurements: $4\frac{1}{2}$ inches \times ($1\frac{1}{4}$ inches \times $1\frac{1}{8}$ inches) \times ($1\frac{1}{8}$ inches \times $1\frac{1}{2}$ inches). I would like to take this opportunity, while writing of a flower in Mr. Wilson's collection, to say that I made a mistake in saying in my notes of April 4 that the lovely Poetaz Rubellite was raised by P. D. Williams; it should have been by J. C. Williams.

The Marquis (R. H. Bath) is a very refined, deep yellow Ajax—practically a self—distinguished by the rich, sleek texture of its flat, right-angled perianth and its shapely trumpet. The specimens on the stand were oldish blooms, but age had made no ravages in its beautiful appearance. The flowers are borne on long, stiff stems. Like Vauban, it was raised by the exhibitor. Dimensions: $4\frac{1}{4}$ inches \times ($1\frac{1}{2}$ inches \times $1\frac{1}{4}$ inches) \times (2 inches \times $1\frac{1}{4}$ inches).

Maid of Honour (Chapman).—I often envy Mr. Chapman's intimacy with the late Rev. G. P. Haydon, for in him he was associated with a great character, and “characters” are invariably interesting people. I have always been told that Mr. Haydon was a man of very sudden impulses. One moment he would pour on you the full vials of his wrath, but a second after the sun would shine and he would be as jolly as a sandboy, and nothing that he could do for you would be too much. One day a generous impulse seized him when Mr. Chapman was in his garden, when, as it so happened, they were looking at a dainty little white (or *very* pale bicolor) trumpet. “You like it, do you? Well, it is yours. I give it you.”

AN EFFECTIVE GROUPING OF CHOICE WATER LILIES.

That is the history of how the fascinating Maid of Honour came to be one of the three best—if not *the* best—things in this interesting seedling collection on this particular date. It is a little like Mrs. Robert Sydenham. Size: $3\frac{3}{8}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{1}{2}$ inches) \times ($1\frac{3}{8}$ inches \times $1\frac{1}{2}$ inches).

Vacuna (Barr) seemed to me to stand out among the group of new home-raised seedlings, although many good judges considered an unnamed Giant Leedsii (No. 1276) to be a better flower. The reason that I differed from them was that I thought the perianth was too large in proportion to the size of the cup. Vacuna may be described as a massive pale bicolor Ajax, quite away from such varieties as Averil, Cygnet or Florence Pearson, inasmuch as there is very little recurve in the brim of the somewhat wide trumpet. There seems to be an opening for this type. Measurements: $4\frac{3}{8}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{3}{8}$ inches) \times (2 inches \times $1\frac{3}{8}$ inches).

Midas (Wilson) is one of the many beautiful flowers that have been raised by Mr. J. C. Williams. It is also one of the exceedingly large progeny of that great giver of "good things," Princess Mary. It has a well-formed, imbricated, white, reflexing perianth of much substance, with a large, palish yellow cup, edged with a narrow band of red. Measurements: $3\frac{1}{2}$ inches \times $1\frac{1}{2}$ inches. I call it a restful flower, which very much belies the appearance that its name suggests.

Among some of the other flowers which caught my eye on my tour of the hall were Glyngarth, a sturdy bicolor giant incomparabilis; Veronique, a pure white, loosely built Leedsii of much distinction; Tantalus, an old type Giant Leedsii, which received an award as a cut flower; Elgiva, a Barrii with a very uncommon coloured ruddy buff cup; and Queen Primrose, a pale squat trumpet $4\frac{3}{8}$ inches ($1\frac{3}{8}$ inches \times $1\frac{5}{8}$ inches) \times ($1\frac{1}{2}$ inches \times $1\frac{7}{8}$ inches). JOSEPH JACOB.

SEASONABLE NOTES ON VEGETABLES.

Runner Beans.—Make a sowing in a box in a cool house for an early crop. Directly the plants are above the soil, remove to a cold frame to induce a hardy, stocky growth, which will much facilitate progress when the plants are put out.

French Beans.—Sow half-a-dozen Beans in a 4-inch pot in a cool house, to be transferred to 8-inch pots later on for growing in a cold frame for successional supplies. In a week or ten days time a sowing should be made in the open on a warm border if the soil is of a light character; if heavy, sow in pots in a cold frame for planting out later.

Broad Beans.—A final sowing in the open should be made for the latest crop, although one still later can be made where Beans quite small are required for special use.

Onions.—The plants sown under glass and grown on in boxes will now require planting into their permanent quarters. The ground

having been finally forked over after giving a dressing of soot and wood-ashes, with a sprinkle of lime, choose a dry day to rake over the surface and mark out the rows. If these are to be in beds with an alley between, allow 2 feet for the latter. The beds may be 6 feet or 10 feet wide, according to the number of plants required; 15 inches between the rows will suffice, and 13 inches from plant to plant. Lift the plants carefully with a trowel, retaining a good ball of soil to each, so that the plants will receive little or no check to growth. Do not bury the bulb, but keep it on a level with the soil. Should the weather be dry at planting-time, gently water the plants in to induce a quick root action.

NARCISSUS CRYSTALLINE, A PURE WHITE VARIETY OF THE LEEDSII GROUP, WITH A FRILLED TRUMPET.

Afterwards keep the soil moved between the rows, and occasionally dust the plants over with soot.

Peas.—Sow now, for use in August and September, varieties like Duke of Albany, Alderman, Quite Content or Superlative. Do not sow the seeds nearer than 3 inches apart; this allows ample room for a full development of the haulm, without which good pods cannot be secured. If the ground was well manured and deeply dug or, better, trenched, nothing beyond a forking over now in dry weather will be required before drawing drills 4 inches deep for the seeds. Should the weather be dry, well soak the bottom of the drills before sowing, which hastens germination considerably. Keep a sharp look-out for mice, which, if numerous, will quickly spoil the row by eating

the seeds. Nothing is better for clearing these pests than two ordinary bricks, one stood on edge, the other canted on its edge, so that it is propped up to the other brick by a piece of stiff wire 2 inches long, baited with toasted cheese.

Leeks should now be planted from the pots or boxes in which they were raised into trenches taken out 2 feet deep and 18 inches wide. The bottom of the trench should be broken up at least 6 inches deep. On this place a layer of half-decayed farmyard manure at least 4 inches deep; then a layer of old potting soil, into which the plants are transferred from the pots or boxes with a good ball of soil attached to the roots. If the weather is dry, give a good watering after planting, also make sure that the plants are sufficiently moist at the roots before planting.

Carrots.—Make successional sowings thinly in rows 15 inches apart for the strong-growing varieties like the Intermediate type. For the Horn varieties a foot between the rows is ample. Thin and hoe among plants well above the soil.

Brussels Sprouts from the second sowing should be planted out as fast as the plants are ready. It is a mistake to allow the plants to become drawn up weakly in the seed-bed. Plants 4 inches high are large enough, as at that stage they plant with less fear of a check. Too often the seed is sown too thickly, which means weakly plants. It is far better, when there is a risk of this being so, to thin out the weaker-growing plants in the beds, as this allows more space for the remainder.

Salsify should be sown in drills 15 inches wide. If the soil is heavy or stony, make holes with an iron bar at least 2 feet deep to ensure straight roots, as when the seedlings meet with obstructions, as stones or hard clods, they make fangs, and are not suitable for cooking, apart from appearance. In sandy soil this trouble is not experienced.

Sowing seeds such as Broccoli, Cabbage, &c., in the open in beds is at times difficult to accomplish satisfactorily, owing to drought, which often prevails during April and May, when many vegetable seeds should be sown. It is a common practice with the uninitiated to sow the seeds and water the beds afterwards, which creates a crust on the surface, making it difficult for the tiny seedlings to push through. The best way to ensure success is to dig over the beds roughly and give the soil a thorough soaking the day before sowing the seed, and shade them with mats to prevent the too rapid evaporation of the moisture from the soil by the sun's rays, assuming, of course, the weather is hot and dry at the time. The next day the clods will easily fall to pieces. The seed can be sown and lightly covered with some old potting soil, again applying the shading until the plants are coming through the surface, when it should be gradually removed, affording light and air to induce a stocky growth. Lettuce should be sown every fortnight in drills where the plants are to remain, thinning out the plants as soon as large enough to handle, and planting in other drills previously watered.

Swanmore.

E. MOLYNEUX.

GARDENING FOR BEGINNERS.

HOW TO RAISE AND GROW ASPARAGUS.

naturally light soils very fine crops of asparagus can be grown without much trouble. The expense is not great, but the cultivator must

opening material may be put in, as the trenching proceeds, where the drainage is poor. Do not bury such material too deeply—18 inches below the surface will do nicely.

Planting.—In cold soils and in the Northern Counties the end of this month will be soon enough to put in plants or seeds. In the Southern Counties and where the soil is naturally light, the middle of the month will do. On a fine day, and where the ground is dry, fork up the surface soil and leave the subsoil, represented by No. 1 in Fig. A, undisturbed. Then form shallow ridges, as shown at No. 2, 18 inches apart; these ridges need not be more than 3 inches or 4 inches high. On them carefully place the young plants so that their roots may be evenly spread out, as shown. Strong two

—DIAGRAM TO ILLUSTRATE THE PLANTING OF ASPARAGUS. NOTE THAT THE PLANTS ARE ON SMALL RIDGES BEFORE BEING COVERED.

prepared to wait at least two years before he can reap remunerative crops, as it is very unwise to use Asparagus before it is strong enough to withstand the cutting. Both heavy and light soils must be deeply trenched before seeds or plants are put in, as, once established, the plants remain for many years, and the cultivator has no opportunity afterwards of making good any defect in the formation of the beds below the surface. Only top treatment can be given after the plants are growing. If the soil is light and sandy, form the beds in a position where the ground is quite flat, if this is convenient; but if it is heavy and retentive of moisture, then select a plot having a gentle slope, if one is available.

Trenching and Manuring.—The work of trenching should be done in the autumn or winter, convenient, and in the case of clayey land the manure may be put in then; but when dealing with light soils, add the manure in February or early in March by simply forking it in the surface, turning over the soil on it and leaving the top portion as rough as possible. In every case break up the subsoil well. Broken bricks and similar

year old crowns are the best to plant, and they must have a space of about nine inches between them in the rows. Do not allow the roots and crowns to be unduly dried by long exposure to the air, but get them covered up with soil as quickly as possible. No. 3 shows the crowns covered and that portion of the bed finished off.

Sowing.—The same preparation of the soil is necessary as in the case of planting roots, only it will be well to make the surface portion somewhat finer. No. 1, Fig. B, shows the subsoil containing also the rotted manure. Drills must be opened 18 inches apart and 3 inches deep. No. 2 shows the seeds dropped 3 inches apart in the drills and covered 3 inches deep. Rather deep sowing is much better than shallow sowing, because the seeds germinate better at this season, when surface soils quickly dry up, and if the resultant plants are to remain permanently in that position, when cut the "grass" is much finer than after shallow sowing. Every other seedling in the row may be pulled out, if all seeds germinate, while quite small. This and the keeping down of all seedling weeds is all the work needed to be done the first summer. The "grass" must be cut down to within 2 inches of the soil when it is matured in the autumn.

Weakly Roots and Strong Ones.—No. 1 in Fig. C shows a weakly root and crown; the growth resulting from such is shown at No. 3. No. 2 represents a strong crown, possessing plenty of fleshy roots; such plants produce very satisfactory growths, similar to that shown at No. 4. If a period of dry weather comes, do not hesitate to water the young plants freely.

—HOW TO SOW SEEDS OF ASPARAGUS. THEY ARE PLACED 3 INCHES APART AND 3 INCHES DEEP, IN ROWS 18 INCHES ASUNDER.

HOW TO GROW SWEET WILLIAMS.

THESE old-fashioned flowers are again attracting a good deal of attention, and rightly so, for they are showy hardy biennials of the easiest possible culture. To secure a good display next year, seeds ought to be sown within the next few weeks. They may be sown either in the open ground or in pans. The latter method is preferable, and germination takes place quicker and more regular. Pans or boxes of suitable dimensions should be selected and partly filled with drainage, over which is placed a thin layer of moss or rough material to secure a free passage for water. A mixture of loam and leaf-mould put through a quarter-inch mesh sieve is an excellent compost, and the seed ought not to be covered too deeply. Place the pans in a cold frame, and when two or three leaves are made, the seedlings may be pricked out.

C.—POOR CROWNS AND GROWTHS CONTRASTED WITH THOSE THAT HAVE HAD GOOD TREATMENT.

into nursery beds till the autumn, unless their flowering site is available, when they are best planted direct into it. Frequently, however, they must go to a spare bed, whence they are lifted early in October and replanted where they are to flower. Thoroughly drained soil is essential, as the plants are liable to suffer in wet soil during the winter.

Sweet Williams are well suited for shrubby borders, masses in beds, the herbaceous borders and, in fact, almost anywhere that the soil is reasonably good. For most amateurs a good mixed strain is best if purchased from a reliable seedsman; but for those who desire distinct shades I would suggest Pink Beauty (which has delicate pink flowers), Scarlet Beauty and Dark Crimson. Then there is the Auricula-eyed variety, which possess rich colours, with a white eye and margin.

G. G.

S

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruit Houses.

Fig Trees in Borders require careful stopping and thinning. Remove weak growths before the trees become crowded, and stop side shoots at a few eyes beyond the fruits which are swelling. Do not allow the borders to become too dry, or many of the fruits will drop; 65° at night will be quite high enough.

Early Permanent Vines.—If started at the beginning of December, the Grapes will now be colouring. The border should be examined, and, if at all dry, a good watering of weak liquid manure should be applied before the crop is too far advanced. If this can be obtained from the farmyard and diluted with warm water until it is of the required temperature, so much the better. A good sprinkling of soot may also be applied with advantage.

Tomatoes.—Plants from which ripe fruits are being gathered should be given an occasional top-dressing of artificial manure. Confine the plants to single stems by the removal of all side shoots as they appear, and do not allow them to suffer from want of water at the roots. Early spring-sown plants will now be setting their fruits, and should be frequently top-dressed with fine loam in which a quantity of artificial manure has been mixed, and this should be pressed tightly on the surface of the soil. Ventilate freely and keep the foliage well thinned, removing all side shoots as they appear. When a sufficient crop is set, the leading point may be removed from the plants and frequent waterings of liquid manure given. A night temperature of 65° or 70° will suit them well.

Plants Under Glass.

Perpetual-Flowering Carnations which have been flowering throughout the winter and spring may now be removed to some spare pit or shelter in order to prepare them for planting in the open. If these plants are carefully tied to wires or strong sticks, they will produce a quantity of useful flowers in the autumn; but they must never be allowed to become too dry at the roots.

Young Carnation Plants which were struck in December should now be ready for potting into 6-inch pots. Keep the pit moderately close until fresh roots are made, after which the plants must be freely ventilated to keep them from becoming drawn.

Cinerarias.—A small sowing may now be made to produce an early batch of plants. Sow in clean pans of sifted loam and leaf-soil, make moderately firm and sow thinly, covering very lightly with fine soil. When large enough to handle, the young plants should be placed singly in small pots and shaded from strong sun throughout the season. The most suitable position is a cool pit facing north, and the pots should stand on a good bed of ashes within 15 inches of the roof glass.

The Flower Garden.

Tuberous Begonias.—If these have been gently started in boxes, they should now be parted with a sharp knife and potted into 4-inch pots. Place them in a warm pit quite near the glass, but avoid forcing after they are established, for it should be remembered that the sturdier the plants are at bedding-out-time the better will be the results.

Mignonette.—Several sowings of this sweet-smelling plant should be made during the season. The ground should be deeply dug and a good dressing of old manure incorporated with the soil, also a quantity of sifted mortar rubble. When large enough the plants should be freely thinned. It is necessary to make the soil firm before the seeds are sown.

Border Chrysanthemums should be planted out without delay. In order to ensure the best results, these plants should be stopped and thinned out as it becomes necessary. Keep the shoots tied to neat sticks, and never allow them to become overcrowded.

The Hardy Fruit Garden.

Cherries.—As soon as the trees have set their fruit, careful attention should be given to the

destruction of green or black fly, which is almost certain to be present on the young shoots. Syringe the trees with some insecticide as often as it may be necessary, to keep these pests in check. Disbudding should be attended to before the shoots become overcrowded, in order to avoid severe pruning during the winter.

Mulching.—Fruit trees on south walls should receive a good mulching of farmyard manure before the season is too far advanced. The soil should be lightly broken up with the points of a digging fork before the mulching is given, and this should be applied to newly planted trees either on walls or in the open garden. No great quantity of manure should be used so early in the season, as this has a choking effect on the soil; and if mulching is intended for the supply of food as well as a protection from strong sun, the material should be of a rich, stimulating nature.

The Kitchen Garden.

Carrots.—The principal sowing of Carrots should be made as soon as the soil is in working order. Sow in shallow drills a foot apart, and cover lightly with fine soil. As soon as large enough, the seedlings may be thinned to 6 inches apart. Frequent dustings of soot should be applied during the season.

French Beans in pots should be freely watered with liquid manure. Pick the pods as soon as they are large enough for use, and if necessary they may be kept for a few days in a cool cellar. Sowings may now be made in cold pits for the supply of pods at the end of June. If seeds of Dwarf Beans are planted under a south wall, they will be of great value as a succession to those grown under glass.

Runner Beans.—A sowing of Scarlet Runner Beans may be made now in boxes or 4-inch pots, and placed in a cold pit to produce plants for planting in trenches in the open garden about the third week in May. Plants raised in this way have the advantage of protection from rough weather, and may be expected to come into bearing ten days before those sown in the open.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery.—The main crop should now be ready for pricking out, and where only a moderate quantity is required, this may be done in boxes. They should then be placed in a vinery for a time, at least until it is safe to place the plants in frames. Where a large quantity is needed, they may be pricked into frames right away and well protected during cold nights. The trenches should now be prepared for planting, and where possible they should run north and south. The plants must have a rich soil; indeed, it is almost impossible to overdo them in this respect.

Kidney Beans.—A small sowing may now be made on a warm border. With this important crop one has to take a great many risks. If the summer happens to be cold and wet, it is next to impossible to get a crop, more particularly in the North. It will be wise to make a sowing in small pots. The seedlings can be planted out about the second or third week in May. But the safest plan is to make a sowing in some of the cold frames after the bedding plants have been taken out.

Turnip-Rooted Beet.—Seeds may now be sown in lines in an early border. The roots will be much appreciated for the earlier supplies of salads. The sowing of the main crop had better be deferred for at least another week or so.

The Flower Garden.

Dahlias.—As soon as a sufficient stock of cuttings has been secured, place the old tubers in frames. These will be found handy to plant among the herbaceous plants or mixed borders. Treated in this way, they make large specimens and are very effective in the late autumn.

Canterbury Bells and Sweet Williams.—These should be placed in their flowering quarters without delay. It will be as well not to plant

in very large patches, as this would leave some nasty blanks after they had gone out of flower. I find it is a good practice to plant some Montbretia bulbs among them, which will take the place of the former when out of bloom.

Gladioli.—Where it is the practice to plant these without being started, no time should be lost in getting the bulbs out. Should the soil be of a heavy nature, it will be advisable to put a little sand in with each bulb, and see that they are planted at least 4 inches deep.

Early Flowering Chrysanthemums.—Old plants which provided cuttings for the season's stock should not altogether be discarded. These will be found to be extremely useful for giving an early supply of flowers, either planted in some odd corner or in the mixed border. The young plants should now be fully exposed to the weather, and planted out as soon as they are sufficiently hardened. They may be pinched now or after they have obtained a start.

Bedding Plants.—All plants which have been grown in heat should be placed in frames as soon as possible. Half-hardy annuals grown in boxes often receive a check through neglect in watering, so that it will be wise to plant them out as soon as it is reasonably safe. Besides, it relieves the pressure later when there is so much to see to.

Yews.—The clipping of Yew hedges or the more ornate specimens may now be proceeded with. Even at this date they will most likely assume a rather yellowish hue. Still, with the increased warmth they soon recover. Where one has a hedge that does not seem to be particularly happy, it will be found that in most cases the plants are suffering from poverty. In such instances apply a good dressing of rich farmyard manure, and if this is at all unsightly, it can be covered with a little soil.

Plants Under Glass.

Deutzias.—Plants that have been forced will now be passing out of bloom, and should have the old wood cut back to encourage the young growth. As soon as growth commences, they should be repotted and kept growing on in moderate heat until growth is completed, when they ought to be stood out of doors. Plants that have not been repotted must have frequent applications of manure-water. If it is intended to increase the stock, cuttings should be taken off and rooted singly in small pots. These will make useful little flowering plants for next season.

Primula sinensis.—Where plants are required for early flowering, a small sowing may be made now, and as Primulas do not, as a rule, germinate freely, a little extra care will repay the grower. The seed-pans should be well drained and filled with a mixture of about equal parts loam and leaf-soil, with a little sand. The pans should be watered before sowing and allowed to drain. Sow the seeds thinly, cover with a piece of glass, and place in a moderate temperature. They should never on any account be grown in too much heat.

Winter-Flowering Pelargoniums.—A good batch of cuttings should now be rooted for supplying plants to bloom in early winter. These should be grown on in 6-inch pots and kept in frames fully exposed to the sun. The flowers must be pinched off as they appear until the end of August or the beginning of September, by which time the plants should be good specimens. House them not later than the end of September.

Fruits Under Glass.

Grapes Shank.—Although one does not expect Grapes to shank at this early stage, still, it is usually in the earlier stages that the damage is done. One of the principal causes of shanking is that the Vines are planted in too rich a soil, causing them to grow on late in the season; these late roots usually rot, which causes an unequal balance between top and root. Another cause is flagrant neglect of atmospheric conditions. Roots either too wet or too dry, and especially roots that have gone down and away from the influence of the sun; denuding Vines of large quantities of foliage at one time, which causes a severe check; and overcropping are other factors that tend to bring about shanking.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice. The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be early and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on a business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS IN GRASS LAND (H. H.).—We do not see any reason why Sweet Peas cannot be grown in grass land, providing you make the holes a yard in diameter and break up the soil 2 feet deep. Of course, everything will depend on the character of the soil and the treatment plants are given afterwards. You did not, unfortunately, tell us any idea as to what you have done, or in what part of the country you are living.

DAFFODILS NOT FLOWERING (W. Watts).—We think it is quite probable that the reason why your Emperor daffodils are not flowering better is overcrowding. These daffodils increase very rapidly in most gardens, and the bulbs need lifting and thinning every other year to do well. Your best plan will be to lift all the bulbs this year when the foliage has naturally died down, separate them, and plant the strongest in the bed that you wish to have plenty of flowers in next spring. The smallest of them could be planted in a bed of good soil in some other part of the garden, and after having a year there would, no doubt, attain flowering size.

SOWING NYMPHÆA SEED (Winner).—Your Nymphæa seed had better be sown indoors. Place a shallow tub or tank on the stage of a warm greenhouse where it will be exposed to the sun. Then sow the seeds thinly in pans, singly in small pots, filled with loamy soil. Cover the seeds with about a quarter of an inch of compost. The pots or pans must then be stood in the tub or tank so that they are covered by from half an inch to an inch of water. Change a little of the water daily if no means can be found for allowing a little of the water to be continually running in and out. The seedlings ought to appear in a few weeks' time, and if in pans they must be potted singly as soon as they are large enough to handle. Plant the water out of doors when several leaves have been formed and the plants are fairly vigorous. It may be necessary to repot them into 5-inch pots first.

WHERE TO OBTAIN VARIOUS PLANTS (Solent).—Of the several subjects concerning which you enquire, *Alvia involucreta* Bethellii is generally known in gardens and nurseries as *S. Bethellii*; *Chironia linoidea* is usually known as *C. ixifera*; and *Pentas carnea* is a well-known love plant. Any nurseryman who makes a speciality of stove and greenhouse plants should be able to supply these. Apply to Messrs. James Veitch and Sons, Chelsea, or to Messrs. Stuart Low and Co., Bush Hill Park, Enfield. *Encelia Heritieri* is rarely seen outside of a botanic garden, but one of the above firms might keep it in stock. *Calceolaria Forgetii* was introduced by Messrs. Sander of St. Albans, and no doubt they could supply it. For the *verbascums* and rockwork plants, send to Messrs. John Waterer, Son, and Crisp, Wargrave Plant Farm, Twyford, Berks, or Messrs. Thomas Ware and Co., Feltham, Middlesex. Where any particular firm does not stock the plant required after, they will, as a rule, obtain it if possible.

THE GREENHOUSE.

ALPINE HOUSE (Sheffield).—If you cannot find any better position than under the Silver Birch tree, we should

advise you to abandon the idea of growing alpine, and take up choice hardy Ferns instead. One of the essentials to success with alpine under glass is unrestricted light, which nothing short of an open position can ensure. This is even more important when, as in your case, there is some idea of permanent planting. Then, it would appear that the house would have to be of a lean-to character, which also is not good. The best type of house is span-roofed; the best position an entirely open one, which permits of ventilation on all sides as well as the roof. The plants should be grown in pots and pans, preferably in frames or on a bed of ashes in the open in the summer, and taken into the house in autumn. The size of such a house is optional to its owner; it may be a dozen feet long or thrice that length, while a width of 10 feet would serve for all. If soil and stone were used on the staging, the latter would have to be of a substantial character. They are not essential. In the circumstances, we think you had better consider the matter and then write us again.

FRUIT GARDEN.

WIRES ON WALLS FOR FRUIT TREES (G. K. M.).—Yes; wire the walls for the fruit trees. It is possible to fix the wires about half an inch away from the wall, and this will be quite close enough for the branches. When the wires are fixed several inches from the wall, there is a cold current of air passing behind the branches and young foliage, and, in the case of Peaches and Nectarines, in some exposed gardens, leaf blister is then more prevalent. The branches can be kept from direct contact with the wires by twisting the tying material once or twice as you suggest.

MISCELLANEOUS.

ADMISSION TO THE CHELSEA SHOW (New Reader).—The spring show of the Royal Horticultural Society, to be held at Chelsea on May 19, 20 and 21, will be open to the public on Tuesday, May 19, from 12 noon to 6 p.m., admission 10s.; from 6 p.m. to 8 p.m., 2s. 6d. On Wednesday, May 20, from 7 a.m. to 6 p.m., 2s. 6d.; from 6 p.m. to 8 p.m., 1s. On Thursday, May 21, from 7 a.m. to 6 p.m., 1s. At 6 o'clock on this day the show closes. After your *Calceolarias* have done flowering in pots, we do not think they would give any satisfaction if planted out in the garden.

VARIOUS QUESTIONS (A. D.).—The two plants sent for identification are: (a) *Chionodoxa Lucilia*, flowers developed somewhat abnormally; (b) *Pieris floribunda*. The Rose leaves appear to be affected by a fungus disease known as the rose-leaf blotch (*Actinonema rosæ*), but it has not developed sufficiently for correct identification. Spray the plant with a weak solution of potassium permanganate, and, as the leaves fall, collect them promptly and burn them at once. These precautions will probably act as a preventive against the disease appearing another year. The *Rhododendron* leaf is suffering from the presence of thrips, small black insects which prey upon leaves of many indoor plants. They are encouraged by a dry, close atmosphere and improper cultural conditions generally. Fumigate the house with a nicotine preparation once a fortnight, and sponge the leaves now and then with soft-soap water.

NAMES OF PLANTS.—*J. C., Ireland.*—*Narcissus J. B. M. Camm.*—*J. R. D.*—1, *Anemone blanda*; 2, *Chionodoxa Lucilia gigantea*.—*Mrs. S., Holmbury St. Mary.*—Yes; the pink flower is *Andromeda polifolia*; the pale *Anemone* is *A. apennina*; the smaller and deeper flower is *Anemone blanda*.

BOOKS.

The Rose Annual.—The Council of the National Rose Society are to be heartily congratulated on the exceedingly interesting and useful volume now before us. When we remember that this is only one of several publications that members receive, in addition to admission tickets to all the society's shows, it is not difficult to understand the phenomenal increase in membership year by year. Certainly this year's Annual is the best the society has ever published, and it is packed with interesting letterpress and illustrations from cover to cover. Those who are interested in French Roses will read with great pleasure M. Jules Gravereaux's descriptive account of his famous Rose garden at the village of l'Hay. As president of the French Rose Society he is rightly regarded as the leading amateur rosarian in France, and we thank him for placing on record so charming a description of his garden. The classification of Roses is becoming a serious problem, and we expected to find something relating to it in the Annual. Nor are we disappointed. Mr.

Alex. Dickson of Belfast, Mr. W. Easlea, Mr. Peter Lambert, Mr. George Paul, V.M.H., the Rev. J. H. Pemberton, Mr. A. E. Prince, Mr. G. M. Taylor, Dr. A. H. Williams and Mr. George Gordon, V.M.H., all offer suggestions for the rearrangement of our various classes of Roses, and doubtless the Council will be able to derive from these a basis on which to work. We hope to be able to deal with this subject more fully at a later date. Autumn-flowering pillar Roses, for which there is naturally a large demand, are fully dealt with by Mr. H. R. Darlington, and Mr. Pierre Guillot gives some very interesting information about the use of the Rose in the ornamentation of the garden. Then comes a most interesting article on the production of new varieties, by Dr. A. H. Williams. This is splendidly illustrated, and gives the novice some very valuable information about hybridisation and crossing, and the ripening, storing and sowing of seed. Mildew and black spot receive attention from Mr. M. A. Bailey, B.A.; black spot from Mr. H. R. Darlington, who, we believe, has been troubled a good deal with it among his Roses; and Mr. George G. Hamilton puts forward some rather startling ideas about the prevention of fungoid diseases from a surgeon's point of view. Diseases also receive attention from the Rev. F. Page-Roberts and Dr. A. R. Waddell. Mrs. H. R. Darlington, who always seems to have something fresh to say about Roses, and who has the gift of saying it in such an interesting way, gives particulars of the lasting qualities of cut Roses, a subject that is of more than ordinary interest to thousands of rosarians. Dr. H. T. Hinton gives some useful information about chlorosis, or the yellowing of foliage, and Mr. Courtney Page discourses on the budding of Roses, a subject that is always of considerable interest to amateurs. This article is fully illustrated, and is of a highly practical character. "How to Treat Roses the First Year after Planting" is the title of a useful article by Dr. C. Lamplough, while Mr. H. E. Molyneux, whose notes on newer Roses are so highly appreciated by our readers, deals fully with the new seedling Roses of 1913. The illustrations, a number of them in colour, are very interesting and good, and we advise all our readers who are not members of the National Rose Society to purchase a copy of this Annual. It can be had for 2s. 6d. post free from the hon. secretary, Mr. E. Mawley, Rosebank, Berkhamsted; or, better still, send Mr. Mawley 10s. 6d. and become a member of the society, and so secure all the privileges that are extended to members.

THE EDITOR'S TABLE.

Blue Primroses and Polyanthus from Ireland.—Mr. J. W. Brasier-Creagh, Creagh Castle, Doneraile, County Cork, sends some very fine flowers of blue Primroses in two shades of that colour. One, which is particularly charming, is a very large flower of rich blue with a well-defined yellow eye, while the other is deep violet of a velvety texture. In addition, we were very pleased to find some good blue Polyanthus, the best of their kind we have seen. Accompanying these interesting flowers were some wonderful St. Brigid Anemones, grown only as they can be grown in the moist and genial climate of the Emerald Isle. Daffodils from the same source comprised several seedlings, the best

of which was a large bicolor trumpet variety named *Pride of Munster*. Although not quite up to exhibition form, this should prove a good market flower.

SOCIETIES.

THE FERTILISATION OF FRUIT TREES.

A LECTURE of considerable importance to fruit-growers was recently given by Mr. G. O. Sherrard, from the John Innes Horticultural Institute, Merton, to the members of the Croydon and District Horticultural Mutual Improvement Society, at their rooms, Sunflower Temperance Hotel, George Street, Croydon. In practical experience of fruit-growing one finds failures in cropping some kinds, and it is often remarked that failure to set the fruit is owing to climatic conditions, oftentimes frost, prevailing when the blossoms are developed. Perhaps in some seasons this explanation is correct, but it is now obvious to the scientist that there is another reason for the non-bearing of trees—the sterility of the variety. Most noticeable is this in some varieties of Plums, Cherries and Apples, and at the John Innes Horticultural Institute research is being made to detect varieties which are self-fertile and those which are self-sterile. In districts where perhaps a few varieties are grown, one often discovers a dearth in the crop, and it is in cases of this kind that the beneficial results accrue to the scientist's researches. In the Plum family it is found that an equal number of varieties are self-fertile and self-sterile, and from experiments which Mr. Sherrard and Professor Bateson, who is the head of the John Innes Horticultural Institute, are carrying on, they are able to record the fertility and sterility of each variety, and also how the sterile trees may be made productive by cross-fertilisation. Some useful data shown by Mr. Sherrard by lantern slides proved extremely interesting, and gave the audience some idea of the elaborate precautions one has to adopt to make true records of the different crossings. Perfect isolation of the tree must be adopted, and an insect-proof house was shown where many experiments were carried on. Fruit trees are grown in pots, with the top of the pot covered with material tied round the base of the tree to prevent insects which may be hatched in the soil climbing up the stems. Another illustration was a Victoria Plum tree in the open, encircled with muslin to exclude all insects, and this experiment showed that without the aid of insects the blossom did not set. A variety of Plum known as Wyedale, pollinated with its own pollen, was unproductive, but the introduction of pollen of another variety was conducive to a good crop. Mr. Sherrard informed the audience that many experiments similar to these have yet to be carried on, to show which varieties are favourable to each other in production. With Cherries the difficulty appears to be more pronounced, the number of self-fertile varieties being so few. In the Apple it is found that the introduction of pollen from another variety produces bigger fruit in a self-fertile variety, and the variety *Lord Derby* was shown as an example. Gooseberries are all self-fertile, but the pollen is sticky, and where these are grown near a bed of brighter-hued flowers it has been noticed that insects avoid the flower of the Gooseberry. It will be the privilege of this society to visit the home of these researches on June 10, and the awakened interest will be intensified when that evening outing is made.

EAST ANGLIAN HORTICULTURAL CLUB.

At the April meeting of this club, presided over by Mr. John Clayton, there was a strong muster of members to hear Mr. George Herbert discourse upon "Sweet Peas." Mr. Herbert, as all the Sweet Pea world knows, was for several years with Mr. Bredmore, but is now in the service of Hobbies, Limited, Dereham, Norfolk, who no doubt will be doing big things in Sweet Peas in the future. Mr. Herbert detailed his initiation into enthusiasm for Sweet Peas and the way he had worked to bring about the notable varieties that bear his hall-mark. He dealt largely with culture, diseases, preparing for exhibition and kindred subjects in a style that everyone was able to grasp. Following the remarks of Mr. Herbert came a very interesting discussion. Mr. Robert Holmes, Tuckwood, Norwich, himself a great authority and raiser of Sweet Peas, complimented Mr. Herbert upon the way he had dealt with the subject. Mr. T. Notley and Mr. F. Welby, two notable local growers, gave their views of the matter, as did many others. On the exhibition tables Sweet Pea blooms were placed from Hobbies in a fine assortment. The first Strawberries of the season were also staged—fine dishes of Royal Sovereign from several growers.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS' ASSOCIATION.

"Of late years hardy border flowers are rapidly coming to the forefront." This was the opening remark of Mr. B. Pugh of Messrs. J. Carter and Co., Raynes Park, London, S.W., when giving a lecture on "Hardy Flowers from Seed for Town Gardens" on April 6 at a meeting of the above association. The lecture, he said, was more in the capacity of a talk, in which he wished to give his audience many useful hints which might not be known to them before. Through the medium of numerous hand-painted slides he transported to the screen before them many exquisite photographs portraying several hardy border glories of past summers, a number of which had been grown in Messrs. Carter's world-famous trial

grounds. Hardy border flowers from seed are best grown in boxes and transplanted when the seedlings become established, care being taken to guard against frost. The boxes should contain the poorest soil possible. To this a little decayed Coconut fibre might be added in order to provide a germinating food for the plants. For protection in the border itself many devices could be adopted, such as placing a zinc ring an inch in height around delicate seedlings to exclude the slugs from them. One purpose of Mr. Pugh's selection of border flowers was to revive old features; therefore he included not only the most up-to-date annuals and perennials, but several older favourites generally discarded of recent years—*Antirrhinums*, *Everlasting Flowers*, *Ageratums*, *Carnations*, *Dahlias*, *Canterbury Bells*, *Nemesias*, *Poppies*, *Nasturtiums*, *Phlox Drummondii*, *Scabious* and *Verbenas*; in fact, all herbaceous border plants would, he contended, flourish in either town or country areas, provided a liberal supply of lime and plenty of manure were given to them. Muriate of potash applied to *Clarkia* and *Balsams*—absolute essentials for all borders—would be exceptionally beneficial, and an experiment in raising *Dahlias* from seed would amply reward the grower with good samples. At the conclusion questions were invited. Several were forthcoming from Messrs. Herbert, Palmer, Webb, Smith, Parker and Ford. The vote of thanks proposed by Mr. Jones and seconded by Mr. Palmer was carried with much appreciation.

ROYAL HORTICULTURAL SOCIETY.

DAFFODIL SHOW.

THE above society held its Daffodil Show at Vincent Square, Westminster, on April 15 and 16. The fine bank of *Narcissi* arranged by Messrs. Carter, Raynes Park, attracted considerable attention, as much by reason of its naturalness as by the effective floral display. Backed and occasionally interspersed by flowering and evergreen shrubs, there was suggested the massed effect possible in the garden at this time, and certainly no other spring flower is capable of such good work. In this way one was impressed by the free masses of such fine things as *Glory of Leiden*, *Mme. de Graaff*, the red-eyed *Firebrand*, the semi-double *Argent*, *Seagull*, *Queen Alexandra* and the Poeticus-flowered *Hercules*. *Golden Rose* (a rich yellow double-flowered incomparabilis) was also good. The low wall fronting the arrangement, and freely planted with alpine, contributed to the garden effect produced.

Messrs. Sutton and Sons, Reading, contributed a nice assortment of seedling Daffodils, representative of self and bicolor Ajax forms, Poeticus, Leedsii and other sections. That numbered 194, a fine bicolor from *Weardale*, was of splendid proportions. Another very rich yellow was 215, a magnificent bit of colour and shapely withal. The flowers were most daintily and effectively arranged.

From Messrs. R. H. Bath, Limited, Wisbech, came a very fine gathering of Daffodils, particularly noticeable being a handsome white flower with green base to the segments, a striking flower not yet named; *Lady Superior* (a glorious Barrii), *White Pennant* (virtually a *Giant Leedsii*), *Cresus* (a flower of unequalled excellence), and *Lady Mayoress* (also a *Leedsii* of giant form).

The Rev. G. H. Engleheart, Dinton, Salisbury, in the annexe, showed, as usual, one of his unique sets of seedlings. They were here in plenty, rich in variety and beauty, of merit and distinction. That numbered 648, a rich golden yellow, is valuable for its lateness. The triandrus hybrids in the group were also a charming set, appealing both by their size and refinement.

Messrs. Barr and Sons, Covent Garden, W.C., arranged a formidable collection of choice Daffodils, seedlings and the leading commercial sorts being staged in abundance. Seedling 802, a golden yellow Ajax, is a magnificent thing, rich in colour and great in size. *Ruby*, a red cup, is a shapely flower and a gem among the Barriis. *St. Olaf* (*Leedsii*) is a dainty flower. *King Alfred*, *Lord Roberts*, *Blazing Star* and *Cassandra* were all notable and good. Messrs. Barr also contributed alpine.

Messrs. Waterer, Son, and Crisp, Twyford and Bagshot, displayed Daffodils and flowering shrubs, *Rhododendron Alice*, a deep pink-flowered *Pink Pearl*, being conspicuous. The rock garden arrangement from the same firm contained masses of *Primulas*, *Aubrietias*, *Mossy Saxifrages* and the like.

Messrs. H. B. May and Sons, Edmonton, arranged groups of *Clematis*, dwarf *Rambler Roses*, *Calceolarias*, and *Tufted Pansies* in pans.

Mr. Clarence Elliott, Stevenage, contributed a rock group with such as *Gentiana verna*, *Oxalis enneaphylla*, *Androsace villosa*, *Arabis aubrietoides*, *Anemone robinsoniana* and others.

Messrs. William Cutbush and Sons, Highgate, N., arranged *Azaleas* of the mollis and sinensis section, also *Indian Azaleas* in variety.

Messrs. Wills and Segar, South Kensington, displayed a fine strain of *Cinerarias*, *Erica wilmoreana* *King Edward VII.*, with *Stocks* and *Mignonette* of a particularly good strain.

Messrs. Whitelegg and Page, Chislehurst, had a very pretty rockwork arrangement, massing such things as *Primula rosea*, *P. frondosa* and *P. denticulata* in variety. *Meconopsis integrifolia* was very fine, also *Daphne Cneorum*, which was full of its rosy flower clusters.

The double *St. Brigid Anemones* from Messrs. Reamsbottom and Co., Geashill, King's County, Ireland, were, as usual, particularly fine, blue, pink, rose, scarlet, violet, flesh and other shades making a brilliant display.

Mr. Alfred Dawkins, 40, King's Road, Chelsea, had a nice collection of *Narcissi*, *White Queen*, *Albatross*, *Lord Roberts*, *Southern Star*, *Dubloon*, *Magpie*, *Lady Margaret Boscawen* and *Cardinal* all being good.

The *Lissadell Plant and Bulb Farm*, Sligo, had many good Daffodils, *Weardale Perfection*, *King Alfred*, *Flambeau* and *Alannah* being all important and distinct. *Judge Bird* (bicolor) and *Fin MacCumhal* (of big Sir Watkin form) were also excellent.

Robert Sydenham, Limited, Birmingham, had a capital collection of leading commercial sorts, *Mme. de Graaff*, *Vivid*, *White Lady* and *Waveren's Giant* being well represented. Mr. C. Engelmann had a good representative lot of *Carnations*. Messrs. B. R. Cant, Colchester, followed with a good lot of *Roses*, of which *Silver Queen* (single, white), *Lady Hillingdon* and *Richmond* were the best.

In the group from Messrs. Cartwright and Goodwin we noted *Nightingale* (a fine Poeticus), *Morven* (bicolor) and *Scarlet Gem*, all of which received awards of merit.

Mr. Christopher Bourne, Bletchley, staged good vases of *Evangeline*, *Lady Moore* (a fine red cup), *Queen of the West*, *Great Warley*, *Queen of Hearts* (a brilliant-eyed flower), *Mrs. Robert Sydenham* and *Buttercup* in an excellent lot.

Messrs. J. R. Pearson and Sons, Chilwell, had *Lord Kitchener*, *Grey Mare*, *Great Warley*, *Lowdham Beauty* (a superb *Leedsii*), *Horace* (a great Poeticus) and *Orange Gem* in a good lot.

The group from Messrs. Walter T. Ware, Limited, Bath, was among the most telling in the show. *King Led* (an enormous bicolor, with green-backed segments), *Queen of the West* (rich golden) and *Horace* (Poeticus), the latter the finest we have seen of this class, were in magnificent form. *Macebearer*, *Embassy*, *White Slave*, *White City*, *Roll Call* and *Albatross* were all fine. There were many splendid seedlings also in the group.

Mr. W. A. Watts, St. Asaph, had a great massed bank of Daffodils, staging the more popular sorts in considerable numbers. The group was one of the most extensive in the show, but, owing to the method of naming, or rather lack of it, we are precluded from referring in detail to the varieties shown.

COMPETITIVE CLASSES.

In the competitive class for a collection of forty-eight varieties, three stems of each, Mr. A. M. Wilson, Bridgewater, took the lead. His best flowers were *Bersek*, (rich yellow Ajax self), *The Fawn* (*Leedsii*), *Lord Kitchener*, *Leontes*, *Cresus* (a fine red cup), *Lancelot* (*Giant Leedsii*), *Buttercup* (rich yellow), *Cleopatra*, *Countess of Stamford* (pure white Ajax), *Brambling* (a brilliant-cupped form) and *Sunflower* (a flat-cupped variety of distinction and merit). Mr. C. Bourne, Bletchley, was second in this class, having *Cornelia*, *Lord Kitchener*, *Lord Roberts*, *Neptune*, *Bernardino*, *Judge Bird*, *J. T. Bennett-Poë*, *Duke of Leinster* and *Countess Grey* among his best flowers. Mr. F. H. Chapman, Rye, was third, with a nice lot of flowers inclusive of some good seedlings.

In Class 2, for twelve long trumpet Daffodils, Mr. C. Bourne, Bletchley, was placed first, *Golden King*, *White Emperor*, *Lord Roberts*, *Cleopatra*, *Mrs. G. H. Barr*, *Mrs. Robert Sydenham* and *Conqueror* (a fine pale bicolor) being the best. Messrs. Cartwright and Goodwin, Kidderminster, were second, *Mrs. E. M. Crosfield* (white Ajax), *Ben Alder* (a glorious big yellow) and *Fort George* (a bicolor with heavy flanged crown) being very fine.

In Class 3, for twelve incomparabilis, Messrs. Cartwright and Goodwin took the lead, having *Whitewell*, *Wonderland*, *Neptune*, *Great Warley*, *Pedestal* and *Marshallight* among good flowers. Mr. C. Bourne, Bletchley, was second, *Macebearer*, *Great Warley*, *Bernardino* and *Duke of Leinster* being all excellent.

For twelve Barrii Daffodils, Mr. Bourne was in the premier place, *Cœur de Lion*, *Southern Star*, *Cossack* and *Queen of Hearts* being very fine. In this class Mr. F. H. Chapman, Rye, was second, having *Little Tich* and several good seedlings in a capital lot of flowers.

For nine *Leedsii* Daffodils, Messrs. Cartwright and Goodwin led the way, *Nemesis*, *Felstar*, *Thistle* and *Lemon Star* being the best. Mr. W. A. Watts, St. Asaph, was second, his Seedling 229 being a distinct flower.

For nine Daffodils selected from Divisions V., VI. and VII., Messrs. Cartwright and Goodwin were first, *Araby* and *Buttercup*, both rich yellow, being very fine.

In the class for six Poeticus Daffodils, Mr. F. H. Chapman, Rye, had a particularly nice lot, *Ibis*, *Ditty*, with Seedlings 124, 120, 24 and 18, being very fine, the last-named of exceptionally good form.

For six double Daffodils from Division X., Messrs. Cartwright and Goodwin, Kidderminster, were placed first, *Sundown* (scarlet and white), *Tintoretto*, *Plenipo*, *Amphion*, *Royal Sovereign* and *Dubloon* being his set.

For a collection of twenty-four varieties (amateurs) representing the three main sections of the flower, Mr. N. Y. Lower, Presteign, Radnorshire, was adjudged first, having *Noble*, *Horace*, *Lucifer*, *Giraffe*, *Olympia*, *Red Beacon*, *Lord Roberts*, *Weardale Perfection* and *Cleopatra* among good things. The Rev. T. Buncombe, Black Torrington, was second.

For six long trumpet Daffodils the last-named gentleman stood in the first place, *Treasure Trove*, *King Alfred* and *Weardale Perfection* being the best vases. The same exhibitor took first prize for six incomparabilis, his vases of *Homespun* and *Gloria Mundi* being very good.

For twelve distinct Daffodils not in commerce, Mr. P. D. Williams, Lanarth, arranged some brilliant flowers. Unfortunately, the varieties were not named, save *White Wax*, a fine white Ajax.

For twelve seedling Daffodils not in commerce, raised by the exhibitor, Mr. A. M. Wilson, Shovell, Bridgewater, was first with a wonderful lot of flowers, his 424, of *Engleheartii* form and crown, being of a uniform apricot shade throughout. It is a delicate and beautiful flower. *Ainzel*, a chaste flower of white with plectee edge of pale orange, was also choice and good.

THE GARDEN.

No. 2215.—VOL. LXXVIII.

MAY 2, 1914.

NOTES OF THE WEEK.

Tulips after Flowering.—When the choicer varieties go out of bloom, they should have the flower-spikes partly cut back, as if allowed to form seed this would undoubtedly weaken the bulb. The bulbs should not, however, be lifted until the foliage is ripened, after which they may be taken up, cleaned, and spread out on a mat in a sunny position to ripen.

Dwarf Brooms for the Rock Garden.—Many rock gardens will be looking attractive just now, and certainly more interesting, where some of the dwarf Brooms are accommodated. *Androsace Ardonii*, *C. Beanii* and *C. kewensis*, which are now giving their wealth of yellow blossom, are some of the best, and are making a grand display either growing on a ledge or hanging over some of the larger rocks. If it is desired of keeping them in a compact state, the growths should be pruned directly after flowering.

Staking Herbaceous Plants.—Many early flowering plants will now require staking, and it is important that this work should be done early, for if the plants are allowed to assume a straggling habit, it is a difficult matter to make them look quite natural. Before the stakes are placed in position it is necessary to tie in the shoots of such plants as *Asters*; and, in fact, most herbaceous plants will benefit by a careful thinning of the shoots before the plants are tied up. The flower-stems of *Eremurus* should receive support as early as possible. *Pyrethrums* will also require early attention, or the stems may become broken down by heavy rain.

Hybrid Barberton Daisies.—The beautiful hybrid *Gerberas* were raised a few years ago by crossing the well-known *Gerbera Jamesonii* first with *G. viridifolia*, the offspring of this with *G. St. Michael*, the latter being a yellow form of *G. Jamesonii*. Since then, by selecting and intercrossing, a wonderful variety of brilliant and pleasing shades of colour have been obtained, from white to pink, many shades of yellow, orange, sunset, to deep rich purple. A group of these charming plants grown in pots will be found of great value for decorating the conservatory at present time. They are of easy cultivation, and deserve to be grown more than they are, as they continue to flower well on into the summer. In some parts of France they are grown on an extensive scale in the open for market purposes. The credit for this beautiful class of plants is due to Mr. R. I. Lynch, M.A., of the Botanic Garden,

Cambridge, who did much to bring them to such perfection. They are grown wonderfully well there and are at present much admired.

Cottages for Workmen at Wisley.—We understand that the Council of the Royal Horticultural Society intend erecting some cottages for their workmen at Wisley. We hope that, while fully bearing in mind the practical side of these, the Council will also see to it that in appearance the cottages will be in keeping with the beautiful

shade of red, and when kissed by the morning sun is far prettier than the garish colours of such a Tulip as *Keizerskroon*, which seems to be the only one grown in most suburban gardens. There are many other Roses the foliage of which is most charming just now, notably *Marquise de Sinety*, *Shower of Gold* and *American Pillar*. This phase of our national flower ought not to be lost sight of.

The Pasque-Flower (*Anemone Pulsatilla*).—This is beyond doubt one of the most charming of all our native flowers. It is not a common British plant; indeed, it is considered rare. When found growing wild it is usually in a rather dry position over a chalky soil, such as on the chalk downs of Berkshire, where it has occasionally been found. The leaves and flowers are beautiful at all stages of their growth. The flowers are pale violet, downy on the outside, and surrounded by pretty collarettes of feathery green. There are many garden varieties, of which alba the one illustrated, is one of the most beautiful of spring flowers.

The Midland Daffodil Society's Show.

The annual show was held at the Botanic Gardens, Edgbaston, Birmingham, on Thursday and Friday of last week. The show, which is reported on another page, once again proved a great success, and there was a representative gathering of Daffodil experts from all parts of the British Isles. One figure, however, was sadly missed, namely, the late Robert Sydenham, who had always entered so heartily into the success of this great exhibition. Out of respect for his memory the annual dinner was not held on this occasion. At a meeting held in the evening of the first day of the show, it was agreed that the dinner should be held in future.

Planting Flower-Beds.—Now that we are close on the season for bedding out, it is a good time to direct attention to a very common mistake. This is the raising of the surface of the beds so far above the level of the surrounding ground that it is impossible to keep the soil properly

THE WHITE VARIETY OF THE PASQUE FLOWER :
ANEMONE PULSATILLA ALBA.

sylvan surroundings. We commend to their notice the excellent designs published in *Country Life* last week, the result of a National Competition arranged by the Proprietors. These are of the greatest interest at a time when the housing problem is such a serious one.

Beautiful Rose Foliage.—During the last few days we have derived a great deal of pleasure from a small hedge of that grand Rose *Grüß an Teplitz*. The foliage of this is a beautiful warm

watered. Not only is it seen in villa gardens and such places where the experience of the gardener may not be great, but in more pretentious gardens, and even in some of the public parks this error is often made. If the soil is raised up like that of a grave, it often proves to be a grave for some of the more delicate plants. Ample supplies of water may be poured on the bed, but most of it runs off, and the poor plants are practically starved in the midst of plenty.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Japanese Plums in Canada.—The statement made by your correspondent Mr. Bunyard in his letter, published in *THE GARDEN* of March 14 last, that the Japanese Plums, such as Abundance, Burbank, &c., are too tender for the climate of England, greatly surprises us in Canada, who have been growing them, without any evidence of tenderness, for many years quite unprotected, where the temperature sometimes goes to 30° below zero. I have always found them to be quite as little injuriously affected by cold as the European Plums.—CANADIAN, *London, Canada.*

The Hardest Grevilleas.—In the extreme west of the country, a great many Grevilleas, as well as other Australian plants, are regarded as hardy shrubs. Throughout the greater part of England, however, most of them may be looked upon only as greenhouse plants, though a couple at least are fairly hardy in the neighbourhood of London. These are *Grevillea rosmarinifolia*, in which the foliage is by no means unlike that of the Rosemary, while its clusters of curiously shaped flowers are borne in great profusion. The second species, *G. sulphurea*, has dark green,

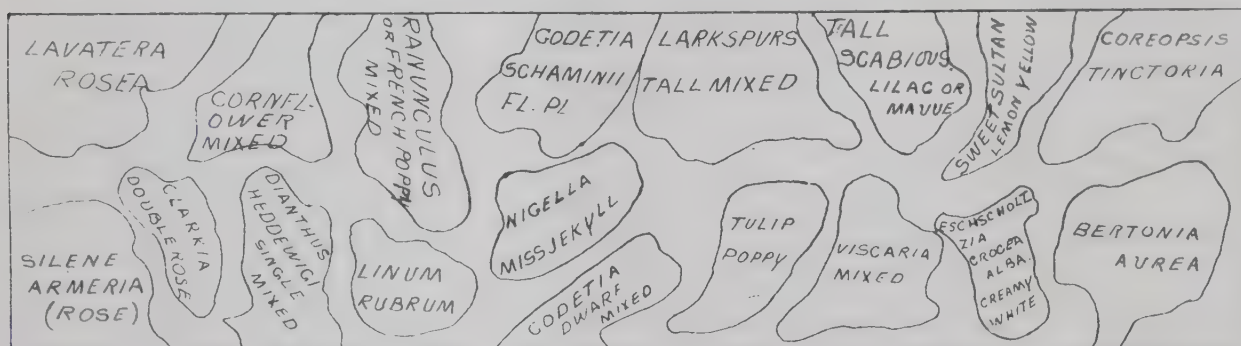

a recognition of similar work done for the flower, and is held by the recipient for one year. In 1912 it was awarded to the Rev. G. H. Engleheart; in 1913 to Mr. P. R. Barr. This year (1914) the recipient is Mr. E. M. Crosfield. He is one of our greatest seedling raisers and a great cultivator. As a showman he has no superior. Few, if any, are the great prizes at Birmingham or in London which he has not won at one time or another. Countess of Stamford, Empire, Ring Dove, Anchorite, Mowgli and Honey Maid are sufficient examples wherewith to illustrate the catholicity of his efforts in hybridising. The choice of the Royal Horticultural Society of this year's holder of the blue ribbon of the Daffodil world is very popular. If he does not talk, Mr. Crosfield works—works hard, shrinks from nothing, even changes his home—for the sake of the flower which he has made his own. I know I express the feelings of all his friends when I wish Mrs. Crosfield and himself length of days, enjoyment and continuous successful endeavours in their new home on the Wye, whither they and their Daffodils flit this summer in their quest of suitable environments.—JOSEPH JACOB.

A White Sport of Saxifraga Boydii.—The statement by M. E. Heinrich, Bavaria, on page 155, that he has a white sport of the beautiful *Saxifraga Boydii* is most interesting, and more interesting still if in course of time it proves to be identical

white-flowered *burseriana* would appear to have entered into both, and a sport or reversion to one of the originals is by no means unusual. What is unusual, which makes the case cited by M. Heinrich doubly interesting, is that he appears to possess not merely a colour sport, but a growth sport or reversion also, which, if presently substantiated, should lend colour to Mr. Boyd's original statement that his unique plant resulted from two white-flowered sorts. What I am curious to know is what this white sport "reported to *THE GARDEN* more than fifteen years ago" has been doing with itself all that time? It would appear not to have been the sporting of a solitary rosette, which might have become crowded out; hence my curiosity. Anyway, I sincerely hope M. Heinrich will get more of these white-flowered variations, and I trust he will let the readers of *THE GARDEN* know about them. In conclusion, I cannot but congratulate your correspondent upon possessing a tuft of *S. Boydii* large enough to make 250 plants. How many such, I wonder, have ever existed?—E. H. JENKINS.

Daffodils with Good Lasting Qualities.—In last week's issue, page 202, a correspondent asks for a list of some of the best lasters in pots. Of these I think *Queen of Spain* easily comes first. Of course, it is not large or showy, but makes a delightful little pot plant, and the blooms last a wonderful time. W. P. Milner, another small flower, is also a tough little fellow which outlasts many of his larger brethren. *Obvallaris* is another. *Maximus* is very good, though not very free-flowering. *King Alfred* is another fine laster, though dear at present for pot work. *Blackwell* is a very good pot plant, and stands longer than many. *Emperor* lasts as well as most, but to my mind is rather big for house work. I daresay your correspondent has noticed that the early varieties last longer as a general rule than the later ones. This is on account of the cooler atmosphere of the room (at any rate at night) and a less powerful sun. No doubt pulling down the blind during the sunniest part of the day would prolong the life of the flowers, but if overdone the plants would become too tall. When grown outside, *Lucifer* is a wonderful Daffodil to stand as a cut flower, although it looks frail. Nearly all white trumpet Daffodils are quickly over, and the *Leedsii* are not as a rule very good.—J. DUNCAN PEARSON, *Lowdham, Notts.*

— I cannot say that I have ever made any exact trial of the different lasting properties of Daffodils in pots, but it rather surprises me to hear "M. E. E.'s" experience with *Mme. Plomp* and *Victoria*. Speaking without a book, I should have said the latter would be the longer laster, and it has occurred to me that the box in which they were grown might possibly account for it. *Lucifer*, although it does not look as if it would be, is a marvellous laster. I doubt if there is any to beat it. *King Alfred* and *Blackwell* are two more which have the same good property. Of the cheaper kinds I would suggest *Homer*, *Seagull*, *Fairy Queen* and *Argent*. "M. E. E." is right about *Prince of Austria* as being a superb Tulip and a splendid laster. *Jenny*, *Cerise Gris-de-lin*, *Vermilion Brilliant*, *Arms of Leiden* and the very new *De Wet* are some that are worth a trial, and which I think will be found to give satisfaction. If a double is wanted, nothing is much better than the old *Murillo*.—J. J.

A SUGGESTED ARRANGEMENT FOR A SMALL BORDER OF HARDY ANNUALS, THE WHOLE TO BE CARPETED WITH DWARF WHITE ALYSSUM.

needle-shaped leaves and yellow flowers. Both are decidedly interesting and ornamental evergreen shrubs.—H. P.

A Border of Hardy Annuals.—These plants are now so popular and their merits so generally recognised that further introduction seems unnecessary. The accompanying small sketch has been prepared to indicate how the seed may be sown broadcast, so as to avoid the straight line and formal block system. No pure white clumps have been introduced because of the ground-work being white. Where such a plan commends itself, there may be a desire to duplicate some favourite varieties, which, of course, can easily be done by eliminating some of those mentioned. In the case of sowing a very long border, the whole or part of this design could be repeated, if so wished, and in the event of so doing I would suggest cream, pale blue, or lilac to follow on the yellow shades. Arrange, if possible, for the border to be get-at-able from back and front, while very wide borders should also have stepping places or a narrow walk so as to facilitate the work of sowing, thinning and staking.—C. TURNER, *Ken View Garden, Highgate.*

The Barr Cup for Daffodils.—The Barr Cup, which commemorates the great work of the late Peter Barr on behalf of the Daffodil, is awarded annually by the Royal Horticultural Society as

in habit with the more vigorous-growing *S. Boydii* alba. The interest in the case centres chiefly in the fact that the raiser of *S. Boydii* first distinctly stated that this queen of yellow Saxifrages resulted from two white-flowered sorts—I believe, speaking from memory, *burseriana* and *rocheliana*—and it was not till the plant flowered at Kew some years later that the now generally accepted parentage of *burseriana* x *aretioides* was suggested. Subsequently, when the late Mr. Dewar, then hardy plant foreman at Kew, wrote the text to accompany the coloured plate of *S. Boydii* in *THE GARDEN*, he made the statement—which, I believe, I have committed to memory aright—that *S. Boydii* alba "was obviously of the same parentage." Now, no two forms are more distinct than *S. Boydii* and *S. B. alba*, and why Mr. Dewar should have written "obviously" when the thing was not, and is not, obvious I do not know. The last named is not only distinct in colour and in the substance of its flowers from *S. Boydii*; it is distinct in stature, and remarkably so in its vigorous habit of growth and genial nature. In *S. Boydii* alba there is nothing to suggest either *burseriana* or *aretioides* influence, though much to suggest such a combination as *burseriana* and *rocheliana*—so much so, indeed, that I have repeatedly wondered whether the raiser had confused them in his mind. In any case, the

Chionodoxas Improving when Established.—Pressure of other matters has prevented me from stating that during the many years in which I have cultivated the Glories of the Snow, my experience has been that they have improved considerably after being planted. In many cases newly imported bulbs have done but poorly the first year or two, and have greatly improved afterwards. They love deep planting, as a rule, and in some cases it appears to take a few years before they reach their proper depth, which they can do by means of "droppers," as do some other bulbs.

Bulbs for Spring Planting.—Mr. Jenkins (age 191, April 18) has drawn attention to what I said in including among bulbs for spring planting the Belladonna Lilies and Alstroemerias. The article was not intended as one for universal treatment of the bulbs mentioned, but was written for those who wished to add to the bulbs they already had some others not in their possession, and which might be planted in spring. I carefully do many bulb dealers keep their bulbs now that they can be planted earlier than formerly, when they had frequently made a great deal of growth before spring arrived. The Belladonna Lilies can often be obtained in quite good condition for planting in the middle of March, and so can the Alstroemerias. The dealers who issue catalogues of bulbs for spring planting include these, and can, and do, supply them in good condition for planting. Personally, I prefer earlier planting, but very frequently with late-ripening bulbs the weather is too severe for planting if they arrive in good time, and I have often found it well into March before they could be entrusted to Mother Earth. As sound general practice, I always recommend planting most bulbs as soon as they can be obtained, but they are often wonderfully accommodated. I frequently plant Alstroemerias very late through choice.—S. ARNOTT.

Fungus Disease on Chionodoxa.—Last year I noticed that one plant of small colony of *Chionodoxa sardensis* was undersized and looking generally unhealthy. A closer inspection showed the anthers to be filled with a quantity of purplish dust-like spores, similar to those frequently seen in the anthers of *Gene cucubalus* and allied plants. I submitted the diseased spray to Mr. Arleton Rea, hon. secretary of the British Mycological Society, who identified it as *Ustilago Vaillantii* (Tul). Apparently this is the first record of the fungus appearing in Britain. I think it is very likely to have been overlooked in other gardens, and it would be very interesting to hear of its occurrence elsewhere and if it confines its attacks to the genus *Chionodoxa*. This year I find two more plants in my little patch are affected, in spite of immediate removal of the diseased flowers last year. The mycelium is probably perennial in the bulb, and I should be glad to know if there is any way of preventing its spreading other than by burning the infected plants. I have a good patch of *C. Luciliae* growing a few yards away, as well as *Scilla bifolia* and *S. sibirica*, but so far these are untouched by the fungus.—NORMAN G. HADDEN, *St. Audreys*.

Malvern. [The fungus *Ustilago Vaillantii* is not new to England, though it is not often noticed. It was first recorded in "Grevillea" in 1893, when it occurred in England and in Ireland, but had been noticed in England six or seven years before that. It attacks *Scilla bifolia*, *S. maritima* and possibly some other species of *Scilla*, some of the *Muscari* and the *Chionodoxas*, being perhaps most frequently seen in *C. sardensis*. We have had it in our own garden, and have seen it several times from others. You are quite right in thinking the mycelium to be perennial in the bulbs. The bulb base is filled with it, but we do not think it is liable to spread to other plants. Like most of the smuts with loose spores, in all probability the young developing seeds are attacked before they leave the fruit, and then all through

NEW HYBRID TEA ROSE PRINCE CHARMING, SHOWN BY MESSRS. HUGH DICKSON AT THE SPRING ROSE SHOW IN LONDON LAST WEEK.

their life the fungus will manifest itself in their flowers. It is, therefore, safer to remove the affected plants as soon as they are seen, so as to reduce the danger of young seedling plants being attacked.—ED.]

SAXIFRAGA BURSERIANA AND ITS VARIETIES.

CAN those of your correspondents who doubt the distinctness of the forms of Burser's Saxifrage be possessed of the best commercial varieties of this unique species? This is a question which naturally forces itself to the front, since, if the varieties of this plant are not as distinct as "chalk from cheese," they are certainly as distinct as many so-called species, and equally so for garden purposes. Some of your correspondents refer to the "type," not knowing, perhaps, that the type of to-day is a glorified form of that which did duty for it in former years. The plant that I knew as *S. burseriana* for nearly thirty years was of a very tufted, cushion-like habit, the small, creamy white flowers set on inch-high peduncles. To-day the type as exhibited is a vastly superior plant, with whiter and larger flowers, longer peduncles, and more glaucous. Beside it the old plant is not worth growing.

The first great break away was sent to the late Mr. Selfe Leonard as the type from "a new locality." This proved to be the true major variety, which I always class as the aristocrat of the lot. This is characterised by large, sparkling white flowers, the slightly crimped petals having crenated margins. It is almost, if not quite, unique in its meadow-sweet-like fragrance. The habit of the plant, too, is distinct, in that it spreads laterally and does not tuft. The rosettes, too, are large in proportion to the flowers. That recently shown as *crenata* is in the same way in some respects, but is not so good. *Gloria* has considerably larger flowers than major, but they are flimsy in texture by comparison and dead white, minus the glistening sparkling surface, which is one of major's greatest charms. Then, of course, *Gloria* has a decidedly and densely cushioned tuft. In size the latter is only equalled or surpassed by *magna*, which has yet to come to the front. It is also of cushion-like growth. *Speciosa* has the smallest rosettes of leaves, and is the latest to flower.

Reference has also been made to *tridentata*, but the name is a misnomer. Whoever saw a Burser's Saxifrage with a thrice-parted leaf or petal? Its correct name is *tridentina*, which it takes from the Tridentine Valley, in which it is found. It is a good and useful form, virtually a tufted major. Unfortunately, much confusion has been brought into being by the thoughtless use of such names as major, *grandiflora* and the like being applied to any slightly larger form. It must not be forgotten, however, that Burser's Saxifrage is an exceedingly variable plant—variable in size of flower, flower quality, stature, tufted or spreading habit, and time of flowering. Does anyone wish for more than these?

Then, more than one reference has been made to disbudding. But how can a plant characterised by one-flowered peduncles be disbudded at all?
E. H. J.

SOME BEAUTIFUL POPPY-WORTS.

THE MECONOPSES.

WHILE it is exceedingly improbable that this somewhat fastidious genus of Poppyworts will ever yield anything more surpassingly beautiful and imposing than the blue-flowered *M.*

Wallichii, there is not the least doubt that the introductions of recent years, while imparting variety and furthering interest in more than one department of hardy plant gardening, have done much to increase the popularity of the group as a whole. In this connection, doubtless, no species has played so important a part as *M. integrifolia*, discovered a few years ago by Mr. E. H. Wilson when plant-hunting for Messrs. Veitch in the high mountain borderland of China and Thibet. It was a great—indeed, unique—find, while its importance to gardens—albeit it is not grown by everyone with success—cannot well be over-

again in the hope that sooner or later we shall discover the secret of their special needs and lift the veil from their apparently insatiable desires. To the precise conditions prevailing in their mountain home not a few alpine, judged by their success in lowland gardens, would appear more or less indifferent, absence of high altitudes, snow and a protracted definite resting period affecting them but little.

So much, I fear, cannot be advanced with respect to all the species of *Meconopsis*, *M. integrifolia*, for example, in some instances apparently influenced by the long-continued mildness and growing conditions of recent autumns, having shown a desire to flower close upon the ground at that season. It has been so here in the humid Thames Valley practically at sea-level, in the breezier district of Sheffield bordering on the moors 700 feet above the sea, and doubtless in other places, and, of course, these precocious ones are never of use again. Happily, so far, it is not a large proportion of any batch which flower thus early, and were it otherwise, tantalising though it would be, it would have to be endured, seeing it is impossible

no attempt should be made to cultivate it under glass, a pernicious system destined to rob the plant of its finer colour attributes and mar the general effect.

As is common with all plants raised from seeds, variations both of leaf colour and form occur among these *Meconopses*, with, in some instances, slight colour deterioration. The worst offender that I have known in this respect is *M. racemosa*, some of the shades of colour being positively vile. What the progeny of such would be would not be easy to predict. To save seeds from the best of them in order to perpetuate the good remaining is the natural recommendation in such a case, though it would be not less interesting or instructive did someone raise a generation or two of these retrogrades in order to ascertain what latent influence there still remained. In the cross-breeding of certain types of florists' flowers it is well known that in the first generation seedlings of a retrograde character are the rule, the superior flowers following from these retrogrades a generation later. One wonders whether some influence akin lies hidden in the inner recesses of some of these Poppyworts. The point is certainly worth deciding.

E. H. JENKINS.

(To be continued.)

DAFFODIL NOTES.

THE ROYAL HORTICULTURAL SOCIETY'S 1914 SHOW.

FOR the third time of asking the Royal Horticultural Society has had a Daffodil show in the large hall in Vincent Square. There is no impediment that I can see in the way of this being the start of a long series of annual exhibitions. That which is now under review was full of encouragement. Never have I seen the hall so full of Daffodils. The trade response was grand. The competitive classes attracted more entries than on either of the two previous occasions. Altogether it was a Daffodil show the like of which has never been seen in London before. Yet some of us must have been conscious all the time of there being something wanting. We sadly missed the magnificent trumpet exhibit of Mr. E. H. Krelage and the superb exhibits of Mr. E. M. Crosfield. What a lot salmon-fishing will have to answer for! I do not mind it taking

the Foreign Secretary from the House of Commons, but it is a different matter when it keeps a Crosfield from our great annual show.

And then, poor Miss Currey was an absentee. Owing to ill health her choice and valuable collection had to be dispersed last autumn. Never again will there be a Lismore exhibit with its characteristic display of bright red eyes and refined white trumpets. To see "Tommy" Jones busying about brought back memories of the past, for it was he who in later years always arranged her blooms.

The distinguishing features of the show were first, the number of trade exhibits. Two—these

TULIPA STELLATA, A BEAUTIFUL LITTLE SPECIES WITH YELLOW AND RED FLOWERS. THIS RECEIVED AN AWARD OF MERIT WHEN SHOWN BY MESSRS. BARR AND SONS IN LONDON LAST WEEK.

estimated. Prior to its coming there was nothing like it, and since that time no species has been introduced to equal it.

In my opinion, we have within the limits of these twain, whether regarded from the standpoints of imposing grandeur or flower beauty, the pick of the whole genus. They rank high in the estimation of all gardeners who know their worth. Nor does one's love or appreciation diminish one iota because of the difficulties surrounding their cultivation, or because failure, either partial or complete, characterises our efforts concerning them. Rather are we in admiration drawn nearer to them, trying them again and

to prevent it. At the same time a number of plants so flowering militates against the good effect that might have been in other circumstances. To some extent this inclination to premature flowering may also be due to a check—a standstill condition it may be—during dry weather; and seeing that these plants are moisture-loving by nature, care should be exercised that they do not suffer from lack of it at any time during the developing season of the rosettes.

Doubtless we have much yet to learn of the likes and dislikes of this fine plant, for which at its best no praise is too great. Not the least of its merits is that of complete hardiness; hence

of Messrs. Barr and Sons and Messrs. J. Carter and Co.—received the very exceptional honour of gold medals. The rewards were the same, but the displays were totally different. Barrs had a more or less conventional group, with a centre full of seedlings and choice varieties in small quantities or as single blooms, while on either side were large vases of the cheaper and more plentiful ones. Carters gave us a sample of Daffodils in masses under trees. Some may scoff at such efforts and talk in Robinsonian lingo of the artificiality that must necessarily be theirs; but I see in these stiff masses an educational purpose which it is impossible to achieve in any other way in the limitations of an exhibition hall, namely, the general effect of the different kinds when planted in a mass. Suttons departed from anything I have ever seen them do, inasmuch as their small, artistically arranged group was composed entirely of their own seedlings.

Mr. Watts of St. Asaph filled a large space against the wall immediately on the right of the entrance door. He had many new seedlings of his own raising, together with large masses of some of the best trade varieties. I mention this group because I instinctively couple it with the many flowers, of which a very large proportion must have been seedlings, that he exhibited in the competitive classes. For some years we have seen this gentleman's "home-made" blooms in London, Birmingham and elsewhere; but the time seems to have now arrived when he is able to exhibit them "on a grand scale." It is hardly necessary for me to speak of the increased interest that this will give. In former notes I have spoken of the efforts of Mr. Bourne to get away from the "formal and bank-like arrangement of groups hitherto adopted." His exhibit marked the high water of his endeavours, and his display called forth many remarks of appreciation. Its general plan was as follows: A brown velvet curtain at the back, with green covering for the top of the staging and the tiered half circles, which gave it its most distinguishing features.

Next in order to the trade exhibits, which both because of their number and their quality mark off the London show from all others, I would like to deal with the competition in the second and third sections of the schedule. It was good. Only in one class out of twenty-four was there no entry, while in all but two there was some competition, culminating in no fewer than six collections being staged in Class 55 for thirty-six varieties. I have taken some pains to make a little inventory of all the varieties in the amateur and novice classes that gained first and second prizes, and in the large one just mentioned (Class 55) of the third prize collection also. In these twenty-four classes there were 173 varieties distributed among the above prize-winners. Of these, only sixty-five were staged more than once and thirty-nine more than twice. As statistics similar to what I have got out seem generally popular, I feel I cannot do better than publish the results of my census in detail. Shown ten

times: Weardale Perfection. Nine times: Lady Margaret Boscawen. Seven times: Noble and King Alfred. Six times: Lord Roberts, Homer, Argent and Horace. Five times: Evangeline, Mme. de Graaff, Orangeman and Homespun. Four times: Bernardino, Incognita, Golden Rose, Florence Pearson, Glory of Noordwijk, Seagull, Virgil and Lucifer. Three times: Ptarmigan, Cassandra, The Colonel, Harold Finn, White Queen, Bennett-Poë, Queen of Spain, White Lady, Lowdham Beauty, Diana, Whitewell, Pilgrim, Beacon, Sunrise, Solfatare, Plenipo, Chryseis, Gloria Mundi and van Waveren's Giant.

A MAGNIFICENT GROUP OF MECONOPSIS INTEGRIFOLIA IN THE GARDENS OF MR. W. A. MILNER, TOTLEY HALL, SHEFFIELD.

Twice: Sulphur Phoenix, Elvira, Barrii conspicuus, Mrs. H. J. Veitch, Torch, Monarch, Waterwitch, Candidata, Vivid, Royalty, Albatross, Dorothy Kingsmill, Giraffe, Olympia, Armored, Mrs. R. Sydenham, Bullfinch, Branston, Marguerite Durand, Phyllis, Sidney, Dante, Ideal, Lemon Queen, Castile and Barcarolle.

The last feature that I have room to touch upon (I am leaving details of the more important novelties till my next) is the record number of varieties that were placed before the Narcissus committee for awards. I did not count them, but I have been told there were more than fifty. Anyhow, they were so many that a special sub-committee was appointed to do some weeding out. Eight plants gained awards, viz., Lady Superior, a white-perianthed Barrii; Nightingale, a well-formed early Poet; Scarlet Gem, a brilliant red-eyed Poetaz with yellow perianth; Golden Sceptre, a Jonquilla hybrid, figured in the 1913 "Daffodil Year Book" as Marigold; Morven, a pale bicolor Ajax; Princess Juliana, a deep yellow Ajax with a boldly edged trumpet; Southern Gem, a pale Giant Leedsii; and Admiration, a tall, striking yellow and red Poetaz. Of these awards, that of Admiration was for the garden and that of Southern Gem for the garden and cutting, while the remainder were for show. The prizewinners in the various classes were dealt with in the report that was published last week. In a subsequent issue the novelties at the Birmingham show will receive attention. JOSEPH JACOB

AN ANNUAL FOR SANDY SOIL.

THE PORTULACA.

THERE are many amateurs who have to contend with a very light, sandy soil, which in hot seasons seems to dry up in almost no time, and so causes endless labour with the watering-can. Ground like this can, of course, be greatly improved by a liberal addition of heavy clay or loam and cow-manure: but if the garden is of any size, this works out very expensive, and consequently

in most places only a small portion can be done at a time.

Now, although most kinds of plants delight in a medium loam, there are a few which thrive well in that of a very light nature, and the Portulacas are one of these. They are dwarf-growing little subjects, eminently suited for rockeries or for edgings, and are best sown in the open border where they are intended to bloom; but, being half-hardy annuals, they must not be put in until all danger of frost is over and the weather appears settled. The latter half of May is about the best time, and a position fully exposed to the sun must be allotted them. Sow the seed thinly in rows about six inches apart, so that the surface soil can be easily stirred and weeds kept down. Should the summer prove exceptionally hot and dry, watering might become necessary; but it is very doubtful, as the hotter the sun the more brilliant will be the display of flowers. Any amateurs who have very light soils would do well to give this splendid little plant a trial, as the sandier the soil the better it will flourish, and during the whole season it demands practically no attention at the hands of the cultivator. Seed can be obtained of both double and single varieties, and can be had in the following separate colours—crimson, yellow, and white; but I think the mixed is preferable to the separate shades, as it gives such an endless variety, which all blend so well together.

Troon, Ayrshire.

G. B. W.

GARDEN VARIETIES OF ABUTILON.

THERE are few, if any, greenhouse climbers more continuous flowering than the Abutilons, as they will commence to bloom from the spring and continue till autumn is well advanced, while if a temperature of 50° to 60° be maintained, they will flower even later than that. What is more, they are available for other purposes besides roof and rafter plants, for neat bushy specimens from 18 inches to a yard or even more in height are exceedingly useful for greenhouse decoration. If struck from young growing shoots in the spring, they will form effective little plants in 6-inch pots towards the end of the summer, and are then particularly valuable for the sake of variety.

Another way of treating Abutilons is to grow them as standards, and in this manner they are, from the pendulous nature of their blossoms, seen to considerable advantage. In this way they are particularly valuable for grouping in the greenhouse or conservatory. The cultural requirements of the Abutilons are not at all exacting, as they will thrive in ordinary potting compost. It is, however, as well to bear in mind that they are fairly liberal feeders, and if at all starved at the roots, some of the leaves are sure to turn yellow and drop.

The great variety that we have now in the garden forms of Abutilon would seem to have originated in the pure white *Boule de Neige*, which, though sent out as long ago as 1872, is still one of the very best of that tint. It was sent out by M. Lemoine et Fils of Nancy, and though that firm, with their well-known courtesy, endeavoured, for my information, to trace its origin, they were unable to do so. The advent of a white-flowered form led to the possibility of pink or rose coloured kinds, and in due course the variety *rosæflorum* made its appearance. Although I am not aware of its origin, there is but little doubt it was the result of a cross between *Boule de Neige* and the orange red *A. Darwinii*, a native of Brazil. That the union of these two tints should result in the production of pink flowers is somewhat singular, but a parallel case is to be found in *Rhododendron Princess Royal*, which was obtained by crossing the white-flowered *R. jasminiflorum* and the orange red *R. javanicum*. Another instance is furnished by *Begonia weltoniensis*, a pink flower whose parents were *B. Dregei*, with white blossoms, and *B. Sutherlandii*, in which they are a kind of coppery yellow. Once Abutilons of these distinct colours were obtained, others followed suit, and numerous varieties were quickly put into commerce. Several Continental raisers took them in hand, and in this country the late Mr. George of Putney raised many beautiful kinds,

some of the purplish tints being very striking. The raising of Abutilons from seeds is very interesting, especially if the crossing is carried out in a systematic manner. Plants from seed sown early in the spring will flower the same year, but in the case of any doubt as to the quality of a particular individual, it will be policy to flower it a second season. Of well-recognised varieties it will be hard to beat *Boule de Neige* (white), *Golden Fleece* (yellow), *Sanglant* (deep red), *Anna Crozy* (purplish), *Royal Scarlet* (light scarlet) and *rosæflorum* (rose). Some of the newer varieties, with large, shallow, widely opened flowers, are less pendulous than the older kinds, and by no means as

AURICULA GORDON DOUGLAS. A BEAUTIFUL NEW VARIETY WITH RICH YELLOW AND BRONZE FLOWERS.

graceful. While the above remarks apply to the Abutilon as a flowering subject, there are some remarkable for their handsome leafage, and for this reason alone they are extensively grown. Chief among these are *Savitzii*, whose leaves are clearly variegated with white; *Souvenir du Bonn*, a more vigorous grower with less variegation; and *Thompsonii*, the foliage of which is mottled with gold. The variegated-leaved variety of *A. megapotamicum* or *vexillarium* is also very striking, while of the original species, *A. striatum*, whose rich yellow flowers are veined with crimson, affords a pleasing variety.

H. P.

HARDY PERENNIALS IN SMALL GARDENS.

IT is frequently somewhat glibly stated that herbaceous plants will yield a constant and plentiful supply of flowers from spring to autumn, and certainly this is true, provided one has an extensive garden devoted to a thoroughly representative collection, cultivated with skill and painstaking care; but it has to be admitted that often in a small garden we see herbaceous borders which are but intermittently gay, and sometimes for weeks on end are almost bare of bloom. In many an impulsive denunciation of formal bedding we have been told that *Pæonies*, *Iris*es, *Delphiniums* or *Phlox*es are beyond comparison with *Geraniums*, *Calceolarias* and *Lobelia*; but if the centre bed of a small garden is given over to either of these subjects, the result in the long run is apt to be disappointing. The *Pæonies* are gay for a fortnight or three weeks, and more or less untidy and dull for the rest of the year, and the same drawback applies to the other subjects quoted. Even in a mixed border of small dimensions there is a risk of frequent gaps and scarcity of flowers that in time palls on one, and, maybe, leads to a return to orthodox bedding.

By the exercise of forethought and judgment, however, it is possible to realise one's ambitions for a continuous display of colour and beauty, even in a restricted area, by the use of hardy perennials alone, and with this end in view no plan is so entirely satisfactory as that of carpeting the ground with some low-growing subject, thinly interspersing plants of taller, erect habit to flower at different periods. For instance, a bed may be carpeted with the rosy-flowered *Saponaria ocymoides* or *Dianthus deltoides*, and over the surface of the bed plants of *Delphiniums* may be thinly distributed. Between these some bulbs of *Galtonia candicans* or some hybrid *Gladioli* may be planted, and the result of such a combination of tall plants with a carpet of close-growing subjects will be that the bed is never bare, but always attractive.

Veronica rupestris, *Cerastium Biebersteinii* and *Oenothera missouriensis* are other suitable subjects for carpeting, and we may have *Camassias*, *Montbretias*, *Liliums* or *Liatris pycnostachya* for companions to any of these plants.

A charming little plant for bedding is *Chænostoma hispida*, forming compact little bushes less than a foot high, clothed with a mass of starry white flowers. The plant blooms incessantly, and if some such thing as *Lobelia fulgens* or *Chelone barbatus* is planted at intervals in the bed, the charm of both subjects is enhanced by the companionship.

Dwarf Antirrhinums or Pentstemon Newbury Gem will make a grand display in a bed upon the lawn; but if in early summer Spanish and English Irises occupy the bed, and in the autumn a few choice Phloxes grown on single stems are seen, interest is greatly enhanced, and neither the Antirrhinums nor Pentstemons need suffer. The chief point to observe in planting beds on such lines as these is, first, to plant thinly and then to watch progress, restricting when necessary such plants as tend to encroach too much upon the space that should be occupied by other things. One great advantage of this system of bedding is that replanting only needs to be done about once in three years, and it is also a plan that dispenses with the necessity of glass accommodation for the plants in winter.

HEATHER BELL.

SEASONABLE WORK AMONG ROSES.

THIS is the time when work among our outdoor Roses commences in earnest. Pruning is finished, and the very latest of any except pot planting done. Then there is the spring mulching to complete, and, if this is done early, we get full benefit throughout the growing season. So far as the selection of manures is concerned, we need to pay most attention to the natural character of the soil. Roses enjoy almost any manures, but it is better to put the stiffest upon light and porous soils, with a leaning in the other direction if naturally on the stiff and cloggy side. But there have been quite a number of practical notes upon manures lately, and I only wish to remind readers now of their greater benefit when used at this time of the year.

Very soon our maiden plants will need special attention, and much of their future depends upon how they are handled from now onwards. Where bushy plants are sought, the buds producing only one growth from the eye should be headed as soon as two or three leaves have fairly developed. Most of the Teas and Hybrid Teas push out more than one bud, and are afterwards more free in breaking from the base than the majority of our Hybrid Perpetuals. Due care should be taken not to head a few varieties that produce their best flower from the first shoot in their maiden stages. Let these develop a good flower, and cut this off boldly to within three or four of the bottom eyes when wanted. You will thus secure the finest flower, and generally get a good bottom made for the following year.

Staking.—Unless quite dwarf and robust growers, all should be staked as soon as the Rose eyes push into growth. Do not make the mistake of using unsuitable sticks. The growth of maidens varies so much that sticks or stakes ranging from 2 feet to 8 feet are needed, and it is folly to put the taller ones to the wrong purpose or have the shortest against climbers. A very little thought will avoid this. Do not draw the growth in to the stick with any force. The young shoots need a certain amount of coaxing in the first tie if inclined to grow widely, and they break out very easily.

Keep some good and well-worked soil drawn around the base of dwarfs, as this will assist a better union and keep the whole soft and less

likely to be strained by wind and rains. Suckers will be pushing from young standard Roses, and all shoots below the worked shoulders should be cut out as soon as they can be got at. There is much greater danger of wind breaking the shoots in the case of maiden standards, and all of these need sticks in some form. More persistent heading is advisable here. Several methods of securing are practised, but the one most in favour is a stake of sufficient length and strength to admit of the stem being soundly tied, and with a top long enough to carry the young Rose growth also. As no swaying of the Briar stem is desirable, it pays to take this little extra precaution and make a good job of the whole from the first.

Disbudding.—By the end of May many of our forward plants will need thinning out, *i.e.*, taking away any young shoots that have a tendency to grow inwards or are too numerous for proper or perfect development. This is all the more important with the exhibitor's blooms, who needs

and in not a few instances eggs and germs, with a few insects, often survive the winter in thick growth under the eaves. I would strongly advise the thorough cleansing of such places immediately after pruning, when a more powerful solution might be used than would be safe as growth commences. Cleanliness and careful ventilation are the main points with our indoor Roses, which should now be in full profit.

A. P.

A SHRUBBY CAPE ASTER.

ASTER FRUTICOSUS.

Of this extensive genus the section known as Michaelmas Daisies is so common in our gardens that any description of the plants is unnecessary. There is, however, another section containing a few species with a shrubby habit, most of which are natives of South Africa; therefore they require the protection of a greenhouse during the colder part of the year. *A. fruticosus* is certainly a very

A RARE SHRUBBY PLANT FROM THE CAPE: ASTER FRUTICOSUS. THIS IS CLOSELY RELATED TO THE MICHAELMAS DAISIES.

to curtail quite as much in the number of young breaks as in the number of flower-buds allowed, all the strength going into a less number in order to get the highest quality.

Insect Pests.—Immediately leaves develop upon any shoots, it is well to wash them, even if not attacked by insects or disease. So much depends upon being in time with this work, and the maxim of prevention being better than cure, that no loss is incurred although the pests are not visible. Washing early prevents them from gaining any hold, and cannot be done too soon. At the same time, much less labour and strength of washings are needed than if the enemy is delayed only a week or so after its first appearance. It is upon warm walls and in sheltered corners that we find our first supply of aphides, and these will soon increase and took the neighbourhood if allowed any rest. A more persistent and early use of the syringe is all the more needed in such position because they are less open to cleansing rain.

desirable pot plant, and although it is recorded to have been cultivated as long ago as 1759 in English gardens, it is apparently very rare at the present time.

The plant forms a small shrub from 2 feet to 3 feet high, the woody stems branching out in a zigzag manner. The short, dark green leaves are thickly borne upon the young branches, from which the flowers are freely produced upon slender peduncles during March and April, remaining in a fresh condition for a couple of months. Individually the flowers are about an inch in diameter, with the ray florets of a pleasing purple colour, and bright yellow centre florets. Useful specimens may be grown in 6-inch pots in a compost of loam, leaf-soil and sand, while propagation may be effected by cuttings of the young wood, which root readily in sandy soil, placing them under a bell-glass. Other names by which this plant is sometimes known are *A. fruticosus* and *Diplopappus pedunculatus*.

W. T.

PEACHES AND POT PLANTS GROWING IN THE SAME HOUSE.

MANY amateur gardeners possessing greenhouses like to grow a Peach tree or more, according to the size of the structure, in addition to the usual kinds of pot plants. Some cultivators meet with difficulties and fail to get full satisfaction from the Peaches and the pot plants; others succeed very well. Much has to depend on the situation, but more on the management, generally. At the present time the Peach trees will need the final thinning out of the young shoots and also the removal of some of the young fruits; but the final thinning out of the latter must be put off until the stones have hardened in them. Nature rights itself, as it were, to a great extent. For instance, if a Peach or Nectarine tree—and, in fact, any other kind of fruit tree—is overlaid with young fruits, when the stoning period comes many are cast off, sufficient numbers remaining on to come to maturity. They are, however, always a little below the average size, and the tree, in perfecting the crop, is checked and much weakened. No tree should be put to such a strain, and that is the reason why cultivators commence, while the fruits are small, to gradually remove all except those sufficient to form a good average crop. The trees bearing such crops are not weakened, and are strong enough to continue to perfect such crops year after year. It is only advisable to leave a crop on a little above the average—one fruit to a square foot of wall or wire surface—in the case of young trees possessing extra vigour. The result of the heavy burden is, of course, to check such luxuriant growth and to bring the tree to a more normal condition—one suitable for bearing good crops every year.

Of pot plants, such as Ferns and Streptocarpi may be grown very well if placed where there is least light under the trees. Fuchsias also do well; so do Gloxinias, *Francoa ramosa* (Bridal Wreath), tuberous Begonias and some of the fibrous section. These must be grown on a low stage, or on boards placed on bricks on the border. When pot plants are grown on the stage over the border in which the roots of the fruit trees are growing, there is sure to be a constant drip when the plants are watered from time to time. The result is a soured surface soil of the border. Counteract its bad effect by carefully scraping off the top crust only, and then scatter a small quantity of dry unslaked lime on it.

With regard to ventilation, the contents of the house considered to be of most importance must have first consideration. Usually air can be admitted from this date, which will prove beneficial to both Peaches and pot plants.

Watering the border soil is a very important matter, as the surface may be moist while the soil below is really dry.

GEORGE GARNER.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

***Pyrus Malus floribunda purpurea*.**—A very showy and good variety of a well-known plant. The colour of the flowers, however, is red, not purple, as might be imagined from the name. Exhibited by Mr. R. C. Notcutt, Woodbridge, Suffolk.

ANTIRRHINUM MELROSE, A NEW ROSE PINK VARIETY
SAID TO BE PERPETUAL FLOWERING.

***Arabis aubrietioides* Trevor Seedling.**—A particularly good deep-coloured variety of a valuable rock plant, which will be welcomed by all lovers of choice hardy flowers. The plant is vigorous in habit and free-flowering, and, rightly used, is capable of creating new features in rock or wall garden scenery. From Mrs. E. Lloyd Edwards, Bryn Oerog, near Llangollen.

***Clematis montana superba*.**—Some half-dozen specimen plants of this fine variety of the Mountain Clematis were shown in conjunction with the typical kind to display their worth. The flowers are snow white, larger and much purer in colour

than either the type or its variety *grandiflora*. To good hardy climbers it is an additional plant of merit and distinction. From Messrs. George Jackman and Sons, Woking.

***Antirrhinum Melrose*.**—This is an obviously robust-growing form of the majus type, a pink-flowering and—it is said—perpetual-flowering variety to boot. It has been exhibited on more than one occasion of late, and the question that naturally arises is: Would not other varieties specially treated do just the same? As shown it was very charming, and of a delightful pink shade. It is, we believe, grown largely in America.

From Messrs. W. Wells and Co., Merstham.

***Campanula cenisia alba*.**—Those who know the great charm of the typical rock-loving *Campanula cenisia* will welcome this pure white form of it, which is at once good and choice. That it may baffle the attempts of the amateur at the start, we are quite prepared to admit; but if those who seek to grow it to perfection will starve it, make it what it really is, a purely saxatile species, all will be well. It is really a delightful plant. From Messrs. R. Tucker and Sons, Oxford.

***Polyanthus Orange King*.**—The solitary plant shown of this evidenced a remarkable break in colour, combined with great vigour. The dominant colour shades are orange and red, with a groundwork of old gold colouring. It is many years since an award has been granted to a variety of this group, but no plant has more justly merited it than the above. From Mrs. Ellis, Lincoln.

***Hydrangea Lillie Mouilliere*.**—A deep pink-flowered variety of considerable attractiveness and merit. It is apparently an easy doer. From Messrs. Stuart Low and Co., Enfield.

***Tulipa stellata*.**—A delightful plant in every way. The dominant colour of the rather long, lance-shaped petals is golden, the exterior of the outer petals flamed scarlet and bordered with white. A charming rock garden plant. From Messrs. Barr and Sons, Covent Garden, W.C.

All the foregoing were shown before the floral committee of the Royal Horticultural Society on the 21st ult., when the awards were made.

***Primula Ville de Nancy*.**—A very showy novelty with rich rose carmine flowers, whose pronounced lacerated petals produce a distinctly fringed characteristic. The new-comer is apparently one of the *cortusoides* x *Veitchii* hybrids, and in the soft downy foliage bears strong resemblance to the last-named species. From Messrs. Piper, Bayswater and Barnes.

***Amygdalus persica rosea flore pleno pendula*.**—A fine standard of this, with stem 7 feet or so high, was shown to demonstrate the good pendulous habit of the variety. The flowers are rich rose colour and very attractive. Shown by Mr. L. R. Russell, Richmond.

These two novelties were granted awards of merit by the Royal Horticultural Society on April 15.

RAISING ORCHIDS FROM SEED.

ONE of the most progressive signs in horticulture is the fact that in almost every garden there is a desire to improve the different classes of plants, and to this end thousands of seedlings are raised annually. Orchids are no exception to this rule, and as seeds of most rare plants are usually offered

SEEDLING ORCHIDS POTTED SEPARATELY IN SMALL POTS. SOME ARE SHOWN PLUNGED IN A LARGE PAN OF COCOANUT FIBRE REFUSE.

for sale, I see no reason why the great Orchid firms should not do likewise. The price, of course, would depend upon the value of the plants used for crossing and the possibilities of securing a percentage of good varieties out of the resultant seedlings. Plants with seed-pods have already been offered for sale, and if amateurs could buy seed, there would, no doubt, be a great impetus given to the trade.

The illustration above shows a pan of *Cypripedium* seedlings a few months old, the largest being placed singly in 2-inch pots and the smallest plants two in a pot. I have chosen *Cypripediums* because they are easily raised, and any amateur who contemplates taking up this interesting branch of orchidology would do well if he or she started with *Cypripediums*, or any of the terrestrial kinds.

When to Sow.—Seed should be sown, directly it is ripe, around the base of older plants belonging to the same genus for preference, although this is not essential. Select a specimen that will not require repotting for at least twelve months, and see that the surface is free from moss or any growth that is likely to choke the seedlings or impede germination. The soil ought to be just below the rim of the pot; then there is not so much fear of the seed being washed away. Several plants should be picked out for this purpose, because it often happens in the most up-to-date establishments that seedlings only germinate on one pot or seed-bed.

How to Sow.—After giving the host plant a good watering, the seed may be sprinkled evenly over the soil with the blade of an ordinary knife. From now onwards the soil must never become dry, but extreme care should be exercised in giving water. If seed is sown in only a few pots, the receptacle may be stood in saucers of water

until it rises to the surface, and, failing this method, a fine-rosed watering-pot can be employed. With ordinary care and attention, germination will take place in six weeks or two months, as a general rule; but the grower must not be impatient in this respect, as I have known seedlings to appear twelve months and even longer after the time of sowing the seed.

Removing the Seedlings.—When they have made one or two tiny leaves, they may be removed with a pointed stick and placed singly in a 2-inch pot, as shown at the bottom of the illustration.

The pots are filled with sphagnum moss, cut up rather finely, and all the large heads are picked off when sorting out the rubbish and slugs. When all the seedlings have been planted, the pots are plunged in some old peat or other moisture-holding material, as shown in the first illustration, and lightly sprayed over directly the moss looks dry. As growth advances, larger receptacles must be provided, and a little fibrous peat incorporated with the sphagnum moss. It is essential that the plants should be kept continually growing until they reach the flowering stage. A moist, buoyant atmosphere must be maintained, especially during the spring and summer months, and a minimum temperature of 55° to 60° Fahr. Shade them from all strong sunlight, and never allow

them to suffer from dryness at the roots. An important factor in the raising and growing of Orchid seedlings is cleanliness, for, if once they get a bad attack of thrip, it takes them a long time to recover. Where this pest is present, the house must be vaporised at once, and another good plan is to spray the plants with a solution of some reliable insecticide at fortnightly intervals.

T. W. B.

AURICULAS FROM SEED.

THE enthusiastic grower of Auriculas will be anxious to raise some seedlings, and at this season, when these beautiful flowers are appearing, a short note on the subject may be useful, for the late Mr. Ben Simonite says a man is not worthy of the name of florist if he does nothing in the way of seedling-raising to improve the flowers he cultivates.

The selection of parents is very important, and only the best varieties should be crossed. It is also advisable to mate a green-edged variety with another belonging to the same group; selfs should be crossed with selfs, and so on; while among the alpines the yellow-centred forms should be crossed together, and this remark also applies to the white

and cream centred kinds. Having selected an Auricula which it is intended to use as the mother plant, the anthers must be removed with a pair of sharp-pointed scissors before the pollen is distributed. When performing this operation, hold the plant in such a position that none of the pollen cases falls down the tube. After two or three days the stigma of the prepared flowers may be dusted over with pollen from another bloom, using a fine camel-hair brush to convey the pollen. The seed should be sown directly it is ripe, viz., about July and August, in seed-pans or ordinary flower-pots. These are filled one-third of their depth with drainage, and the usual potting compost employed. Germination is sometimes rather slow, and after pricking off the first batch the seed-pans may still be retained, because other seedlings will eventually appear. When the young plants have made their first leaf after the two seed leaves, they can be pricked off at the rate of about a dozen in a 3-inch pot. As growth advances they should be placed three in a similar sized receptacle, and at the next potting one in a pot, while a 3½-inch or 4-inch will be large enough for their final move. It usually takes about eighteen months for a seedling to reach its full size. A suitable rooting medium consists of good fibrous loam two parts, leaf-mould one part, and decayed cow-manure one part, which ought to be well mixed three weeks or so before it is required. S.

ERICA AUSTRALIS.

AMONG the early flowering Tree Heaths this species is deserving of notice, as it follows in succession those fine and now fairly well-known species *E. arborea*, *E. codonodes* and *E. Veitchii*, although distinct by reason of the colour of its flowers, which are purplish red and produced in great profusion from March to July. In height it grows from 4 feet to 6 feet. A fine colony of this in full flower, associated with the other species noted, attracted my attention in a Heath border in Dr. Wallis' garden at East Grinstead, Sussex; while as an edging to these taller-growing species, masses of *E. carnea*, *E. cinerea* and many others gave promise of an interesting and attractive feature to be continued for some time hence. Where space allows, a Heath border can be made, one of the most interesting features in a garden, as the wealth of material capable of being utilised, as well as the extended flowering period, provides a display of colour through nearly all the months of the year.

Lindfield

E. S.

SEEDLING ORCHIDS AT VARIOUS STAGES OF GROWTH. NOTE THE INCREASED SIZE OF THE POTS ACCORDING TO THE SIZE OF THE PLANTS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Plum and Cherry Trees in Pots.—Trees which are carrying a good crop of fruit may now receive more liberal treatment. Give frequent applications of liquid manure, and always in sufficient quantity to reach the extremities of the roots. Syringe the trees twice daily and shut up the house early in the afternoon, making the most of sun-heat. Disbudding must be carefully performed, removing all superfluous and misplaced shoots as soon as possible, but it is a mistake to remove too many at one time.

Early Peach and Nectarine Trees in Pots.—The fruits on these trees will now be approaching the ripening stage and should be fully exposed to the sun. A temperature of 65° or 70° at night will suit them well. As the fruits are ripening, syringing should be discontinued, and the ventilators left slightly open at night.

Late Vines.—The Vines in late houses require disbudding, and the most forward growths should be stopped in order to distribute the sap evenly over the Vine. Do not allow the shoots to come in contact with the glass, or they may become damaged by scalding. If the borders are restricted, careful attention will be necessary, so that the Vines may not suffer from want of moisture at the roots. In the case of shy-setting varieties, this must be carefully observed, so that no watering of the border will be necessary during the flowering period.

Plants Under Glass.

Humea elegans.—Plants which have been wintered in 6-inch pots will now be ready for their final potting. Let the pots be clean and thoroughly drained. A compost of turfy loam and leaf-soil in equal parts, mixed with rough silver sand and wood-ashes, will suit them well, and this should be made moderately firm about the roots. Water the plants a day previous to potting, and if the soil is in good condition, no further watering should be necessary before the roots have reached the edge of the pots, when a good watering may be given. Grow the plants in an intermediate house until re-established, after which they may be used for the conservatory or greenhouse. *Humea* plants intended for the flower garden may be allowed to remain in 6-inch pots until the time arrives for placing them in the open.

Caladiums.—Young plants started in small pots should not be allowed to become root-bound, but should be potted into larger pots as soon as ready. The soil may consist of turfy loam, peat and leaf-soil in equal parts, with sufficient rough sand to keep it open. Water sparingly until the roots are through the new soil, after which a good soaking may be given. *Caladiums* grow best in a warm, moist atmosphere, and should be protected from strong sun.

Salvia splendens.—Young seedlings raised early in the year should be potted as soon as ready, in order to encourage clean, healthy growth. Rich loam and leaf-soil, with a good sprinkling of sand, will suit them well. Place the plants in a close cool pit for a few days after potting, but as the season advances they may be grown in the open. Stake each plant separately, and secure to a wire as a protection against rough wind.

Gloxinias.—Young plants should be carefully potted up before they become pot-bound. With increased sunshine, more atmospheric moisture will be necessary, but overhead syringing should be discontinued as the flowers begin to open. Successional plants ought to be potted up as they become ready, and never allowed to become cramped for want of root room.

The Flower Garden.

Standard Plants intended for the flower garden will now be ready for removal to cooler quarters, in order to harden and prepare them for planting in the open. *Fuchsias*, *Pelargoniums*, *Heliotropes*, *Swainsona*, *Calceolaria amplexicaulis* and *Veronica Andersonii variegata* are suitable for this purpose, and should be thoroughly hardened before they are planted out.

Plant Out seedling *Pentstemons*, *Antirrhinums* and summer-flowering *Chrysanthemums* with as little delay as possible.

Primroses may be divided now and planted in the shrubbery or on the banks of the lake. Surplus plants of *Primula kewensis* and *P. obconica* may be planted in a similar position, and if slightly shaded by surrounding trees so much the better.

The Kitchen Garden.

Peas.—A good sowing of Peas should be made now for use in July and August. Sow the seeds thinly in trenches 4 inches deep and cover with 2 inches of fine soil, leaving the remainder of the soil to be carefully worked in among the plants before the sticks are placed in position. If the soil is dry at the time of sowing, the seeds may be lightly trodden into the drills previous to covering with soil, as this will hasten germination by several days. *Gradus*, *Matchless Marrow* and *Royal Salute* are good varieties for this sowing.

Spinach.—This is an indispensable crop in summer, and requires great care to bring it to perfection, especially in hot, dry weather. As the season advances, the situation chosen should be protected from strong sun as far as possible. A border facing north or east should answer the purpose well. *New Zealand Spinach* makes an excellent substitute for ordinary *Spinach* in dry, hot weather, and should be sown in drills 3 feet apart. The warmer the weather the better this plant seems to grow.

Broccoli.—The seeds should be sown without delay to produce plants for next winter and spring supplies. *Autumn Broccoli* and *Hallow-e'en Giant Cauliflower* should be included in this sowing. This Cauliflower is indispensable for late autumn supplies. The heads are well covered with foliage, and remain in good condition for a long time. *Savoys*, *Coleworts*, *Copenhagen Early Cabbage*, *Christmas Drumhead* and *Dickson's Dwarf Green Gem* should be sown now, also *Broccoli*. April is the worst month to contend with so far as a full supply of choice green vegetables is concerned, and for this purpose we sow *Harbinger* and *Milecross Cabbage*, *Dickson's Omega Savoy* and several varieties of *Broccoli*.

Tomato Plants for outdoor cultivation should now be ready for potting into 6-inch pots. Keep the plants in a close pit for a time, and water sparingly until the roots have reached the edge of the pots, after which liberal waterings should be given, and the plants gradually prepared for planting out at the end of the month.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus.—This crop is now in bearing, and it is important that the cutting should be done with caution, otherwise much damage may be done to the crowns. In very cold districts it is a good plan to cover the bed with some litter, not only as a protection from frost, but by this means I have found one gets much more tender shoots.

Cauliflowers.—A sowing may be put in now to give a supply in October, which will be found to be of immense use at that time. A small quantity of guano put in the water will not only act as a fertiliser, but will in many cases ward off the maggot, which is so troublesome in dry seasons.

Peas.—Continue to make successive sowings of the main crop varieties, and those that are coming on should have sticks placed to them when they are 6 inches high, as it is most important that they be kept growing upright. Before sticking, earth up the rows on both sides, which will, to some extent, prevent the plants suffering in hot, dry weather.

The Flower Garden.

Liliums.—Where these are intended to form part of the bedding arrangement, they will now be so far advanced in growth that they may be safely transferred to the open. I always find they never make such fine specimens when allowed to become the least pot-bound. In proof of this, nowhere do we find such handsome spikes as when they are grown in favoured districts where they remain in the ground all the year.

East Lothian Stocks.—If these have been sufficiently hardened off, they should be planted out at once, as there is nothing gained by keeping

them standing in boxes. Before planting, give the soil a dressing of finely ground lime, and in planting allow at least 15 inches to 18 inches between the plants.

Planting Perpetual-Flowering Carnations.

For the past year or two these flowers have become increasingly popular as bedding plants, and, if carefully managed, will succeed well in most situations. Many use old plants that have flowered indoors, but young plants rooted in the autumn make by far the finest display. Perhaps the best method of treating these *Carnations* for this work is to layer some old plants in frames in the autumn as one does the *Malmaisons*. I find we get stronger plants in this way. Young plants which have been pinched should now be planted. These will give a display when the ordinary border varieties are over.

Lawns.—Where bulbs are grown on the lawns, the work of mowing has of necessity to be delayed. No time, however, should be lost in getting to work as soon as the foliage is sufficiently decayed. In such cases, of course, it will be necessary to go over the lawns with the scythe for the first cutting. This will remove all inequalities, after which it should be gone over with a broom to remove worm-casts and other refuse before the lawn-mower is brought into use.

Plants Under Glass.

Cinerarias.—If it is intended to have these in bloom about the end of the year, a small sowing may be made now. In doing so see that the mixture contains a fair amount of leaf-soil free from wireworm, and after sowing place the seed-pan in a cold frame, as *Cinerarias* resent at any stage of their growth the least semblance of coddling. That being so, it is important that the seed is sown thinly, and the seedlings pricked out as soon as they show the second leaf.

Chrysanthemums.—Continue to admit air freely to plants in frames, although it will still be necessary to close the lights at nights. Examine the plants frequently for rust and mildew, and if the slightest sign of rust appears, the leaf should at once be removed, while in the case of mildew a slight dusting with sulphur will in most cases check it. A start must now be made in cutting down plants intended for decorative purposes. After they have been cut back, the frame should be kept closed for a time, and the plants syringed at least twice a day to induce them to break.

The Hardy Fruit Garden.

Strawberries.—Time must not be lost in getting straw placed between the rows to keep the fruit clean. This will also act as a protection. The plants should on no account be allowed to become dry at the roots when they are in flower. On young plants not intended to fruit this season the runners must be cut off as they appear. This will assist in building up the crowns for next season.

Fruits Under Glass.

Vines.—Grapes colouring should have a free circulation of air and the moisture considerably reduced. If the border is sufficiently moist, it may be covered with some sweet meadow hay. This will prevent evaporation and present a clean and tidy appearance. Vines in succession houses will require attention, reducing the bunches and thinning. Such large-berried sorts as *Gros Colman* and *Madresfield Court* ought to have the berries well thinned out at the beginning.

Orchard-House.—As the fruits will now be swelling, the syringe should be used freely to keep the foliage free from fly and caterpillars, which can be detected by the tender foliage curling up. The latter are best destroyed by hand picking, while the fly can be held in check by the syringe or fumigation. Gradually reduce the fruits to the required number, and allow the temperature to be considerably increased.

Melons.—To have a supply of ripe fruit for August 12, the seed should be sown this week. This will be found to be the best crop of the season, inasmuch as it is on during the hottest months of the year. Where one has to depend on hot-beds and frames for their supplies, this would also be the best time to make a sowing. The plants should be ready for putting out about the first or second week in June.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopetoun Gardens, South Queensferry, N.B.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLETS UNHEALTHY (H. K. K.).—We could find no disease on the Violets, and think that possibly they have been kept too close. They require abundance of air and thorough drainage, otherwise they are liable to the attack of botrytis, which causes the leaves to damp off.

DAFFODIL BULBS ROTTING (G. B. C.).—The insects referred to are springtails, and we are doubtful whether they are the primary cause of the rot of the Daffodil bulbs, as they feed for the most part on decaying vegetable matter. It would be impossible to say at this season what the primary cause of the trouble is, but it is quite probable that it is the fungus *Fusarium bulbigenum*, which is doing so much damage this season to Narcissus bulbs.

PLANTS FOR ROOF GARDEN (E. S.-N.).—As you desire evergreen, and presumably carpeting plants, we think such Sedums as acre and album the most suitable. Associated with these a central group of the Cobweb Houseleek (*Sempervivum arachnoideum*) would be very attractive. You might, indeed, cover the whole roof with this plant alone, seeing that it is interesting at all seasons. By disposing it among small blocks of sandstone, a picturesque effect would be produced. If to this white-looking species you would like a contrasting comparison, we suggest the dark green, prettily formed *S. montanum*. In these two you would have free-growing, eminently suitable kinds. We do not think the Iris would be suitable for your purpose.

NARCISSUS DISEASED (Miss S. W. H.).—The Narcissus is attacked by yellow stripe disease, the cause of which is unknown. It is not likely to spread this season, but seems possibly not unconnected with soil conditions of an uncongenial character. Some varieties are more subject to it than others, and plants often "grow out" of it. White Lilies are most likely to be attacked by the Lily disease when they have been open to check by cold winds, or by frost while they are in a growing condition. It would be well to shelter them as far as you possibly can by twiggy sticks or something of that kind from cold winds and draughts, so that the chance of such a check is reduced to a minimum. Possibly an occasional spraying with a solution of potassium sulphide, at the rate of one ounce to three gallons of water, would be of assistance in warding off an attack.

ROCK GARDEN.

TUB IN ROCKERY (Miss L. N. S.).—If you remove the goldfish from the tub in your rockery, it is possible that the water will keep clear. If, however, you decide to do away with the water plant, the tub can be formed into a small peat bed by making holes in the bottom, then placing a foot of broken bricks and clinkers over the bottom. On this place good turves, grass-side downwards, and fill up with a mixture of sand and peat. In it *Rodgersia pinnata* might be planted, or some of the low-growing

Gaultherias or Vacciniums. By using loam instead of peat, *Iris sibirica*, *I. laevigata*, various Primulas and other plants may be grown. If, however, you decide to do away with the water, we think you would find it more satisfactory to remove the tub and use its position for ordinary plants.

TREES AND SHRUBS.

HORSE CHESTNUT FLOWERING EARLY (X. Y. Z.).—It is quite usual for certain specimens of the Horse Chestnut to be several weeks earlier than others in developing leaves and flowers. This phenomenon has given rise to the varietal name of *præcox* being added to the typical *Æsculus Hippocastanum*, to identify the early from the later forms. When a large number of Horse Chestnut trees are growing together, some are usually found which are considerably earlier or later than the majority.

TREES FOR GRAZING LAND (A. J. B.).—You cannot do better than plant *Pinus insignis* in the position you describe. It is perfectly hardy in Cornwall and stands exposure well. It also grows very rapidly, and at twenty-five years of age ought to be from 35 feet to 40 feet high at least. Do not be tempted to purchase large plants; little ones, 1 foot to 2 feet high, will transplant better and be larger at the end of five years than others which might have been 5 feet or 6 feet high at planting-time. You can procure plants from any of the Cornish nurserymen, such as Messrs. Ruse or Messrs. Gill of Falmouth, or Messrs. Treseder and Co. of Truro. They may be from 6d. to 1s. each, or perhaps a little more; we cannot say accurately, as we have not a price-list of the firms named.

THE GREENHOUSE.

PLANTS NOT DOING WELL (Reader).—The plants are damping off, and have doubtless been kept too moist and close. It is essential that such plants as these should have ample circulation about them at all times, and a great help to avoid troubles such as these is to sterilise the soil into which the plants are to be pricked out.

CINERARIA LEAVES WITHERING (Chetwynd).—The appearance of the foliage of the Cineraria and your account of the trouble suggest that it is suffering from being brought into a dry atmosphere after having been grown in a fairly moist one. We think you might possibly get over this, to some extent at least, by hardening off the plants; that is, accustom them gradually to a drier atmosphere before bringing them into the house.

ADVICE ON THE ERECTION OF A GREENHOUSE (T. H. T.).—At the best, the erection of a new greenhouse on the site of an old conservatory would be only a very partial remedy for the trouble complained of. As the spot is so shaded, plants of a quick-growing nature are sure to run up tall and weak. The only remedy is to grow such subjects as Palms and Ferns, which do not object to a good deal of shade. For the erection of a greenhouse apply to one of the advertisers in THE GARDEN. For obvious reasons we cannot recommend any particular firm. All are thoroughly reliable.

TREATMENT OF TESTUDINARIA (G. G.).—As the roots of your Testudinaria show signs of bursting the pot, your better way will undoubtedly be to put it into a larger one. The new pot must be effectually drained, and a very suitable compost may be made of three parts of fibrous loam to one part of peat, with a sprinkling of broken brick rubble and sand. The plant should be potted firmly. We should not advise the use of any stimulant in order to encourage growth. If the pot is well drained, the plant may be freely supplied with water during the growing season, but in winter must be kept much drier. Being a native of South Africa, this Testudinaria should be wintered in a structure with a minimum temperature of 45° to 50°.

KITCHEN GARDEN.

TOMATOES IN BOXES (Nemo).—For single plants a box a foot long and 10 inches wide will be large enough. Top-dressings of soil and manure may be added in due course. If two or more plants are grown in a box, the latter should afford accommodation for the plants in due proportion, the box for a single plant being taken as a guide.

SOWING PEAS (R. G. B.).—Much will depend, of course, on the variety as to the length of the row a pint, for instance, will sow. The shorter and less robust varieties should naturally be sown thicker; thus one pint should be evenly distributed over 70 feet, and for the taller and stronger varieties, such as *Quite Content*, for instance, allow one pint to 100 feet. Unquestionably, Peas, as a rule, are sown much too thickly, the result being that the plants become starved and the duration of the crop is short. Much better results follow by allowing the plants of the stronger-growing varieties from 6 inches to 8 inches in double lines.

FRUIT GARDEN.

BETTER IN VINERY (F. H.).—The beetles are Vine weevils, and often do great damage. The larvæ feed on the roots of various greenhouse plants. Spread a sheet on the ground after dark under the Vines, and then either shake them or shine a bright light upon them, when the insects will drop to the ground, feigning death. Collect them and tip them into a bucket of hot water or water with a layer of paraffin on the top.

STRAWBERRY PLANTS DISEASED (A. B.).—Your Strawberry plants are attacked by the Strawberry leaf spot fungus (*Sphaerella fragariae*). The best remedy for this disease is to cut off all the leaves in August and allow

them to dry on the bed; then set fire to them and burn them where they lie. This will do no harm to the Strawberry plants, and will tend to destroy the fungus. The only thing that can be done at this season is to spray at frequent intervals with potassium sulphide, one ounce to three gallons of water.

PEACH SHOOTS FOR INSPECTION (B. A. J.).—The pest on the Peach is the Peach scale, *Lecanium persicae*. It is to be regretted that measures were not taken in the winter to deal with the pest, for Peach tree foliage is exceedingly sensitive to all sorts of sprays and fumigants, so as to render it dangerous to use them so strong as to kill pests. Probably fumigating with hydrocyanic acid would be the best check, but it is dangerous to apply. This month the eggs of the pest will hatch, and as soon as this happens (and careful watch should be kept), the house should be fumigated with XL All or some similar fumigant.

MISCELLANEOUS.

GRUBS INFESTING SOIL (O. P. Q.).—The grubs sent for identification are the larvæ of the crane-fly, often destructive on lawns and flower borders. Repeated rolling in the evening will often destroy these pests on lawns. In the flower borders you should use Vaporite, and destroy the larvæ on all possible occasions.

VARIOUS QUESTIONS (A. G. M.).—*Antirrhinum Asarina* can be rooted in September under a bell-glass, as one would treat the common *Antirrhinum*. Planted in a warm spot in a fairly rich sandy soil, it will usually survive several years. *Primula Forrestii* is doubtfully hardy in this country, but is undoubtedly more resentful of damp than of cold. The soil in which it is planted must be thoroughly drained, and the plants protected from damp accumulating in their crowns.

WALL PLANTS FROM JULY TO SEPTEMBER (B. M. O.).—The period mentioned in your letter is the weakest for obtaining an effective display in the wall garden, though there are a few plants which are indispensable. The majority, however, are over by the end of June, though in your northern district the flowering may be later than usual. The following are among the best things: *Achillea tomentosa*, yellow; *Campanula muralis*, which usually gives a second flowering; *C. garganica*, in three varieties; *C. Profusion*, certainly one of the best; *Corydalis lutea*, charming in leaf or flower at any time; the *Edelweiss*, *Polygonum vacciniifolium*, *Achillea umbellata*, *A. Heuteri* and *Clavennæ*, and *Zauschneria californica*, the last most effective, with scarlet flowers. How much success might be achieved depends not a little upon the nature of the wall and the method of planting; but by colonising the best—arranging them, that is, in free masses—a good display is possible with but a few kinds. The Cobweb Houseleek is a good plant at any time, and, well placed, always attracts attention. There are others which might extend into July, but would not be effective for any length of time.

DESIGN FOR SUNK GARDEN (V. M. D.).—There is one serious defect in the design for the sunk garden as we understand it from your letter. The proportion is not at all good, the garden being much too narrow for its length. The least width permissible for a garden 118 feet long should be 40 feet, viz., width equal one-third length. If you have not room to widen out the area (when a much more attractive design for beds would be possible), we think you would do well to slightly alter the path design, as shown in Plan I. In the narrow borders at the base of the wall we would plant *Iris pumila*, *Aubrietias*, *Campanula pusilla*, *Dianthus*, *Viola gracilis* and other small-growing plants of similar nature, which would give the effect of a herbaceous border in miniature. The edges of borders along paved walks should be planted with small creeping plants, like *Gypsophila repens*, *Thymus Serpyllum*, *Arenarias*, &c., that would creep partly over the edges of the paths. The circular beds could be planted with *Lavender* or *Rosemary*. The effect of introducing the circles will be to alleviate the monotony of so many straight lines. If it is possible to widen out the centre portion of the garden, as shown in Plan II., a much better effect could be produced. Borders on the top of the walls (we presume they are retaining walls, and not built above the ground level), so that you can get trailing plants to hang down the walls, are necessary to complete the design.

VARIOUS QUESTIONS (A. G. T.).—The question of inducing Hydrangeas to produce blue flowers has of late years aroused a good deal of interest. The change in colour from the normal type is often attributed to the presence of iron in the soil, and it has been applied in various ways, but not always with satisfactory results. There are two preparations on the market for turning the flowers of Hydrangeas blue, namely, *Azure*, which is a speciality of Messrs. William Cutbush and Son of Highgate, and *Cyanol*, which is, we believe, a Continental preparation. Messrs. Cutbush have several times shown very fine blue flowers, which have been treated with *Azure*. The presence of lime in the soil is very detrimental to the production of the desired blue tint; hence the plants should never be given water that contains chalk. Rain-water is the very best. It would have been better if you had commenced applying the preparation earlier, but if your plants are not far advanced it will, no doubt, be in time. Painters' knotting is often used to check the bleeding of Vines, the cut surface being sealed beforehand with a red-hot iron. Dusting the fronds of your Ferns with soot or sulphur will do little towards checking the injury done by woodlice or small snails. Woodlice can be readily trapped by cutting some Potatoes in half and scooping out part of the interior. Then make a notch in one side of the Potato and place it concave side downwards on the stage. The notch will allow the woodlice to get underneath the Potato, which should be examined

in the morning, and the pests dropped into some boiling water. Small pots, with a little dry moss therein, laid on their sides where woodlice congregate also form good traps. They must, like the Potatoes, be examined in the morning. The small snails should be sought for, when dark, by the light of a candle.

NAMES OF PLANTS.—*James Ward*.—The Snowy Mespilus (*Amelanchier canadensis*).—*F. W. A.*—A variety of *Heuchera sanguinea*, but which it is impossible to say from specimen. There are many varieties and hybrids.—*Black Hambro*.—*Rubus spectabilis*.—*J. J.*—Seedlings of *Narcissus Poeticus*.—*Mrs. G. C. G. Poynton*.—The coniferous plants are *Cupressus lawsoniana* and *Cupressus sempervirens* (small). The Maple is *Acer monspessulanum*.—*A. C. P.*, *Ivybridge*.—*Erica hybrida*, an early flowering hardy Heath.—*Doubtful*.—1, *Acanthus mollis*; 2, *Romneya Coulteri*; 3, *Amygdalus nana*.—*W. H. J.*, *Kent*.—1, *Kalmia latifolia*; 2, *Allium neapolitanum*.

SOCIETIES.

THE MIDLAND DAFFODIL SOCIETY'S SHOW.

ONCE more this show, which was held on April 23 and 24, was full of interest, both to the Daffodil experts and to the general public. The show, as usual, took place in the Edgbaston Botanic Gardens, Birmingham, and here we would take the opportunity of thanking both Mr. Herbert Smith (secretary of the society) and Mr. T. Humphreys (Curator of the Gardens) for their un-failing courtesy, and to congratulate them on the success with which the exhibition was carried through. Owing to the recent spell of warm and sunny weather, the early blooms were past their best. Only a comparatively few of the early trumpets were on view. That magnificent yellow self trumpet King Alfred, which usually makes such fine splashes of colour at Birmingham, was only to be seen on one or two stands at the most. There was, however, a wonderful display of white blooms, and seldom have we seen Poets so plentiful at any Daffodil show.

COMPETITIVE CLASSES.

Speaking generally, competition was very keen, with the result that the whole of the exhibition space was filled with blooms of high quality.

In Class 1, for a collection of fifty varieties of Daffodils, there was a keen fight for supremacy. Messrs. Cartwright and Goodwin were successful, among the pick of their varieties being Loch Fyne, White Knight and White Wolf. Mr. C. Bourne, the Rev. J. Jacob and Mrs. Ridley followed in the order named, each of them showing collections representing the different sections of the Daffodil.

Class 2, for a decorative exhibit of cut Narcissi only, arranged against a wall on a space 9 feet by 4 feet, brought together many beautiful and effective groups. The first prize went to Mr. C. Bourne; second, the Rev. J. Jacob; third, Mr. J. A. Kenrick, Harborne. In all of the exhibits the association of Daffodils and foliage plants was very pleasing.

Messrs. E. H. Krelage and Sons were very successful in the classes for trumpet Daffodils, and secured premier awards for six white, six yellow, and the single bloom white trumpet. Their beautiful white trumpet variety Mrs. Ernst H. Krelage was one of the features of the show.

Mr. C. Bourne was most successful with the incomparabilis section. Among other successes, he gained first prizes for six incomparabilis, six Barrii in two classes, and six varieties of any section that have not been in commerce more than four years.

Messrs. F. Herbert Chapman, J. Pope, R. Bruce Waite, A. M. Wilson, E. M. Crosfield, W. F. M. Copeland, S. F. Staffurth, Mrs. Ridley and the Rev. T. Buncombe were all winners of first prizes, and there were others in the field, all of whom contributed to the success of this great exhibition.

The Rev. J. Jacob was another successful exhibitor, gaining first for one of the six incomparabilis classes, and again for twelve Leedsii, while he was a runner-up in several classes. His vase of a seedling named Hela among varieties not in commerce was greatly admired.

As already mentioned, Poets were freely shown. Class 13, for nine varieties of true Poeticus, brought many competitors. The first prize and the Cartwright Challenge Cup deservedly went to Mr. E. M. Crosfield. His blooms of Ring Dove, Lovelace, Iliad and Socrates were each seen in the height of perfection. Mr. Crosfield was also first for twelve varieties that have not been in commerce

more than four years. Here he was showing Orb and Ring Dove in tip-top form.

The Herbert Chapman Poeticus Trophy for six varieties of true Poets that have not been in commerce more than four years was won by Mr. A. M. Wilson. Mrs. E. M. Crosfield won the Walter Ware Challenge Cup for eighteen varieties of obvious triandrus hybrids, and the White Daffodil Trophy for six white trumpets was won by Messrs. E. H. Krelage and Sons.

It is not likely that double Daffodils will ever become really popular. One of the best varieties of this class is undoubtedly Mary Copeland, a cream-coloured variety with a bright apricot and suffused centre. It was shown by Mr. W. F. M. Copeland, and received a first prize.

Mr. F. Herbert Chapman was first for three Daffodils not in commerce. In this class nine flowers were arranged in each vase. The effect of showing varieties in this way is very pleasing and might well be more often adopted.

For a collection of twenty-four varieties, open to amateurs only, Mr. S. F. Staffurth was first with a nice lot of fresh-looking flowers, in which Gloria Mundi, Weardale Perfection and Longfellow were perhaps the pick of a very good collection.

The Rev. T. Buncombe was first for six true Poets: his blooms of Orange Ring, Cassandra and Juliet were worthy of special mention.

Mr. R. Bruce Waite proved a very successful amateur

TRADE GROUPS.

Gold Medals.—Messrs. Barr and Sons, Covent Garden, filled one end of the exhibition hall with a magnificent and varied group that deservedly gained the society's gold medal. Poets formed a strong feature of the group, while King Alfred, Lord Roberts and Monarch were among the varieties which created bold splashes of golden yellow.

Messrs. Bakers, Wolverhampton, had a remarkably good rock garden suitably planted with Saxifrages, Primulas, Phlox Laphamii, Ranunculus amplexicaule, Irises and Genistas. The alpine were neatly planted in pockets between large boulders of sandstone.

Silver-gilt Medals.—The Rev. G. H. Engleheart, Dinton, Salisbury, showed an intensely interesting collection of seedlings of varied forms. The collection excited the keenest interest among Daffodil experts.

Mr. A. M. Wilson, Shovel, Bridgwater, also showed seedlings under number, of very high quality. The varieties named Madrigal and Sonata were exquisite.

There were seedlings of great promise in Messrs. J. R. Pearson and Sons' group from Lowdham. Of the named varieties, Great Warley, Glory of Leiden and Lady Margaret Boscawen were remarkably good.

Messrs. Sutton and Sons, Reading, had a magnificently arranged group, in which every vase of Daffodils was set out to advantage. Albatross, Peveril, Mme. de Graaff and Weardale Perfection were all shown in perfect form.

Mr. C. Engelmann, Saffron Walden, put up an exquisite collection of Perpetual-flowering Carnations, Carola, Sunstar and Pioneer were particularly admired.

Silver Medals.—Messrs. Cartwright and Goodwin, Kidderminster, showed a very wide range of varieties, Glory of Noordwijk, Whitewell and Glory of Lisse, as well as Tulips in variety, were worthy of special note.

Mr. C. Bourne, Bletchley, who was very successful in competition, also had a glorious array of Tulips and a capital display of Daffodils in all their sections. The varieties Queen of Hearts, Seville and capital blooms of The Doctor were much admired.

Robert Sydenham, Limited, Birmingham, staged a representative collection, in which Poets were very prominent. A number of Tulips, such as the golden yellow Bouton d'Or, the mauve-coloured Rev. Ewbank and the crimson Pride of Haarlem proved very attractive.

Mr. H. N. Ellison, West Bromwich, showed Ferns and Cacti in great variety. Adiantums were well represented among the Ferns.

From the Donard Nursery Company, Newcastle, County Down, came a superb collection, in which the massive blooms of King Alfred stood out prominently. Gloria Mundi, too, was well shown, likewise Ethel Porter, Buttercup, Homespun and Seline Malone. This is the first time that we have seen an exhibit from this Irish firm, and they are to be complimented on the quality of the blooms that were shown.

Messrs. Reamsbottom and Co., Geashill, King's County, Ireland, showed St. Brigid Anemones in brilliant shades of blue, pink and scarlet.

Messrs. Walter T. Ware, Limited, Inglescombe Nurseries, near Bath, showed Daffodils of fine quality. The vases of The Doctor, Leo and Cleopatra were specially good, while some of the finest novelties were seedlings under number.

There were other non-competitive groups, including that shown by Mrs. Lloyd Edwards, Bryn Oerog, near Llangollen, comprising a number of new hybrid Saxifrages and the purple Aubrietia Lloyd Edwards.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

THE lecturer at the closing meeting of this association, held in the Wesley Halls, Dumfries, on April 25, was Mr. Oliver of Drumlanrig Castle Gardens. Mr. S. Arnott presided over a good meeting, and introduced Mr. Oliver, whose subject was "A Walk and Talk About Kew Gardens," illustrated by a large number of excellent slides, displayed on the screen by a lantern ably manipulated by Mr. W. A. Mackinnel. Mr. Oliver gave an excellent description of the gardens and their history and leading features, the capital views bringing out the points he wished to emphasise. Mr. Oliver, who was four years at Kew, afforded a large amount of information, new even to some of those who knew the Royal Gardens at Kew fairly well, and quite an enjoyable and profitable evening was spent. On the motion of the chairman, Mr. Oliver was cordially thanked for his admirable account of Kew.

NARCISSUS MRS. ERNST H. KRELAGE, WHICH GAINED AN AWARD OF MERIT AT THE MIDLAND DAFFODIL SHOW.

exhibitor, gaining the Barr Vase in addition to a silver medal.

Mr. C. Bourne gained the silver medal in the championship classes, 3 to 27, and Mr. E. M. Crosfield gained a similar award for his success in other classes.

AWARDS OF MERIT.

Mrs. Ernst H. Krelage.—A magnificent and refined white trumpet. Shown by Messrs. Krelage and Sons.

Idris.—A beautiful flower of the incomparabilis section. Perianth white, pale lemon cup prettily crinkled. Shown by Mr. W. A. Watts.

Evangelina.—Perianth large and white with overlapping segments and a much expanded clear yellow cup. It belongs to the Leedsii group. Shown by Messrs. H. D. Phillips, Limited.

THE GARDEN.

No. 2216.—Vol. LXXVIII.

MAY 9, 1914.

NOTES OF THE WEEK.

The Chelsea Show.—Following our usual custom, our issue for the 23rd inst. will be a Special Double Number. This will be twice the size of an ordinary number and will contain a full review of the exhibits at the Royal Horticultural Society's Spring Show to be held at Chelsea on the 19th, 20th and 21st inst. Next week we shall publish a specially enlarged number, with full particulars of an interesting competition for planning and planting little gardens. Those desiring additional copies of these issues should order well in advance, as there is certain to be a large demand for them.

An Early Row of Peas.—When visiting the gardens at Lockinge, Wantage, Berks, on Saturday last we were particularly interested in a fine row of culinary Peas that were growing out doors beside the wall of one of the fruit-houses. The variety was Pilot, and the plants had nearly finished flowering, many pods 2 inches long being present. Mr. E. Harriss, the gardener, informed us that the plants were raised from seeds sown in boxes on January 13, and planted out in their present quarters about the middle of March. We think this creates a record for earliness in the district.

Rose Fortune's Yellow at Terregles.—A grand sight has been presented for some time by a large plant of Rose Fortune's Yellow on the roof of the large conservatory at Terregles, Dumfries, the residence of Mr. C. E. Galbraith. The structure is gay with other flowers, but this Rose almost monopolises one's attention, so fine is it with its flowers of large size, which are exceedingly fragrant. It is planted in the border, and is a picture of health and beauty. The flowers are literally in hundreds, and, especially when seen from the exterior, they have been immensely admired by visitors.

Two Beautiful Greenhouse Heaths.—At the last two or three meetings of the Royal Horticultural Society such grand flowering examples of *Erica cavendishiana* and *E. wilmoreana* King Edward VII. were shown so as to make one long for a return to favour of these charming flowers. The clear yellow blossoms of *E. cavendishiana* cause it to stand out conspicuously among greenhouse Heaths, and this newer form of *E. wilmoreana*, with its masses of reddish pink flowers, is a great improvement on the older kind. Although such a desirable Heath, the

early history of *E. wilmoreana* seems to be unknown, as also does that of the universally grown winter-flowering *E. hyemalis*.

A Beautiful Dwarf Iris.—The accompanying illustration represents a fine cluster of the charming little *Iris pumila* in Mr. W. A. Bilney's rock garden at Weybridge. Mr. Bilney writes as follows: "I find this a particularly easy plant to grow, planted in sandy soil with a little mortar rubble and in full sun. I never trouble to water it during the droughts we have on the fiery soil here. Divided soon after flowering, the plants increase at least fourfold in a season. It is specially well adapted for the alpine garden, as it is dwarf and very floriferous. I grow three

district it was flourishing in marshland amid acres of the common Marsh Marigold, another wilding that is not half so much appreciated as it would be did its possession entail a strenuous journey to Thibet or some other distant country.

Thinning Out Apricots.—In early districts the fruits will now be set, and one generally finds that Apricots set in clusters. They should be promptly thinned out, and in doing so take care to leave the most promising and best-shaped fruits. The trees must be attended to several times, as it will be found that they do not all set their fruits at the same time.

Japanese Maples in the Greenhouse.—Though the various Japanese Maples are not affected by

the winter frost, their young unfolding leaves are of so delicate a nature that the harsh weather so often experienced in the spring prevents them from giving of their best. A few, notably *Acer palmatum sanguineum*, will do well in most districts, while in sheltered spots many of them will thrive. Where the conditions are not so favourable for their outdoor culture, they form a very pleasing feature in the greenhouse, as with the protection thus afforded them the leaves, even of the more delicate kinds, develop without check, and retain their beauty for a considerable time. When a change is desired, they can be plunged out of doors.

A Beautiful Flowering Crab Apple.—The *Pyrus* family provides many beautiful flowering shrubs, and *P. floribunda* is one of the most graceful of them all. The blooms, which are borne in great

A BEAUTIFUL GROUP OF IRIS PUMILA IN A SURREY ROCK GARDEN.

varieties—dark blue, light blue, and yellow. The prettiest is the light blue, but the other two perhaps flower more freely."

Acres of Golden Gorse.—When visiting Bournemouth last week we were particularly pleased to find, in the Highcliffe district, many acres of Gorse flowering more freely than we have seen it before. In some instances the bushes were 10 feet, or even more in height, while others were not more than 10 inches. Yet every little shoot was a bouquet of brilliant golden flowers, which, when kissed by the early morning sun, created a picture such as it would be difficult to secure with any other wild flower. The Gorse is growing in all kinds of soil, from peat to sand, and in the Christchurch

profusion, are drooping, and suspended on rather long stalks. In the bud stage they are of a coral red, and as the blooms open they become lighter in colour. It is a very useful shrub for forcing, but when treated in that way the flowers are much paler, and when fully expanded are pure white. Either as a lawn shrub, bushy tree, or as standards to form an avenue—a splendid example of which may be seen at Paddockhurst, Sussex—it is most decorative. Neither budding nor grafting is necessary in the case of this Japanese flowering Crab Apple, as cuttings strike readily if formed of clean, well-ripened shoots and inserted in the open ground under conditions favourable to rooting.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

An Early Rose Bloom.—I do not know what date constitutes a record for a really good early Rose, but it may interest some readers of *THE GARDEN* to know we had a good flower of Climbing Mrs. W. J. Grant open on April 27. The plant is trained on a wall having a south-south-east aspect. C. T., *Highgate*.

Newly Planted Chionodoxas.—With regard to the various remarks that have appeared in your columns for some weeks past relating to established *versus* newly planted bulbs of Chionodoxas, in my opinion the reason why newly planted bulbs do not produce flowers equal to those of established ones is because the bulbs do not receive a fair trial. Too often they are left until the autumn before they are planted, lying in some dry store or bulb merchant's shop for three or four months at the time when they should be in the ground making roots. If the bulbs are planted at a good depth about June or July, they will produce flowers equal to those that have been planted a number of years.—F. G. PRESTON, *Botanic Garden, Cambridge*.

Salvia farinacea.—This is one of the perennial plants that it is convenient to treat as an annual. Being a native of Mexico it would probably not succeed in our colder Midlands, but in the better parts of our climate it is a charming and uncommon-looking flower of the later summer. There is a white variety, but the typical colour is a fine bright purple. When the spike is half developed it is curiously like an exaggerated form of Lavender. It enjoys a hot summer such as we have not often had of late. It may be raised from cuttings, but is most usually grown from seed, sown early in heat, pricked off and put out with other summer plants in May or June.—G. JEKYLL.

Sweet Pea Trainer or Support.—I found last year the best support for Sweet Peas, running up to 8 feet or 10 feet, is to run chair cane, the unpolished or second-class kind, between posts on each end of the rank at intervals of 6 inches in height to the top, which may be a bar of wood not too heavy, and to tie upright strands to these horizontal ones at the same intervals from the top to the bottom. This cane is cheap—about sixpence a quarter of a pound—is warmer than wire, and does not sag like string. It lasts for years. If soaked in water for ten minutes it is as easily tied as string, and stiffens when dry. I have never seen it mentioned in any gardening book, and thought you might mention it in *THE GARDEN*, to which I am a subscriber. The size of the cane I have used is No. 3 and No. 4. The strands run about 15 feet or 16 feet long.—E. RIGHTON, *Bristol*.

Bulbs for Spring Planting.—One is pleased to note (see page 215, May 2) that, after all, Mr. Arnott does not, in his heart, agree with late planting of these things generally, and that, as a matter of fact, what was written on page 191,

if I interpret the matter aright, was rather intended for the laggards than for the more zealous cultivator who, doing his best by a plant, requires from it its best in return. What we may do from time to time as a matter of convenience or expediency should not, however, cause us to recommend without qualification what, as Mr. Arnott admirably puts it, is opposed to "sound general practice." In these days Lilies are retarded by the million for obvious reasons, and much as one admires their flowers at all seasons of the year, one cannot close one's eyes to the belittling effects—chiefly of flowers and stature—produced. The principle is that of a small loaf being better than no bread; and, moreover, the future of the plants so treated does not concern us in the least. Year by year fresh supplies are forthcoming, and those that have

SALVIA FARINACEA, A LITTLE-KNOWN PLANT SUITABLE FOR SOUTHERN GARDENS.

been—it is human nature paralleled in the vegetable world—were only valued for what could be got out of them. It is not so, however, with all bulbous plants, and those in particular that the amateur would like to plant and see grow in beauty and stature each year. For such as these, the only royal road to success is that of planting in season and in reason. Just how far even the experienced cultivator may go—how far he may overstep the season's border-line of planting with impunity—is still, however, a moot point. Generally speaking, scaly and tunicated bulbs cannot be retarded—or even their planting deferred, which is the point at issue—with impunity; they suffer in the present, their future is hopeless or success jeopardised. On the other hand, certain corms

or tubers may long be preserved—mark the word!—by intelligent cultivators in the dry or dormant stage, with—I say it advisedly—comparative impunity. Hence I am afraid I cannot agree that "Belladonna Lilies can be obtained in quite good condition for planting in the middle of March." I know they are offered for sale at that time, and so, too, are Madonna Lilies, and we know why. A dry bulb of the former in mid-March has been out of the ground six months too long, its apparent soundness but a delusion and a snare, as its subsequent behaviour would abundantly prove.—E. H. JENKINS.

Eighteen Daffodils with Lasting Qualities.—In reply to "M. E. E.," page 202, issue April 25, I also grow flowers in pots for one window, and have found the following last well, though I use gas to light the room: Earliest yellow trumpets—Tenby (*Obvallaris*) and Excelsior; this latter is handsomer than Golden Spur. Bicolor trumpets—Mme. Plomp and Grandis; Mme. Plomp is perhaps the best of all; I love its happy, healthy-looking trumpets; they always seem to me to be sounding forth a triumphant "Te Deum Laudamus." Grandis is a good pot plant, with beautiful blue-green foliage. William Goldring is a graceful, swan-necked Daffodil, and W. P. Milner very like it in miniature. The bulbs of both are small, so that one can plant several in a pot, and produce a good effect; both have slender, drooping ivory trumpets. Two good yellow starry Narcissi are Frank Miles, "the frightened Daffodil," looking like a horse, with its ears laid back, just going to bolt; and Autocrat, who is not frightened at all, but well named. So is soaring Seagull, with its wide white wings (an excellent laster). Eucharis-flowered Ariadne and Katherine Spurrell are two of the loveliest ivory white flowers, and best lasting of all. Minnie Hume, though not considered a pot plant, I find most satisfactory; it flowers freely, is delicately fragrant, and superior to many much more costly kinds. Gaily golden and long lasting are little Jonquilla and Odorus Campernella. Among bunch-flowered Narcissi I find Gloriosus the most sweetly scented. It reminds me of Gorse. I grow it singly in tiny pots, bringing one at a time to the flower table, otherwise its perfume is almost overpowering if many spikes are open at once. It is not so showy as Ideal, which lasts excellently. Of double

Daffodils I recommend Argent and Butterfly, both delightful pot plants, growing gracefully and lasting longer than Butter and Eggs or the beautiful Codlins and Cream, which are, alas, a fleeting joy! I find flower shows, though very delightful, do not tell us the things we want to know about the flowers. One has to grow them and blow them, and many are the disappointments! My plan is each year to get about twenty single bulbs of kinds unknown to me and try them. This gives me much interest and amusement at small expense. So far I find, to my satisfaction, that expensive kinds are not always the best—a most comforting discovery to such a poor person as—ANNE AMATEUR.

Lime in the Garden.—Lime, when used with discretion, has proved very beneficial on land of various consistencies. This, I think, is a generally recognised fact. Although I have never used lime at the rate mentioned by "J. D.," page 143, viz., 1½ st. in a drill 9 yards long, I have used it at about half this quantity, with very satisfactory results, for Potatoes. I can quite understand the good results following the use of lime on sour peaty soil at the rate mentioned above, but should hesitate to recommend it for all soils and situations. It would prove instructive if "J. D." would give particulars regarding the nature of his soil. Respecting "J. D.'s" query as to lime as a dressing for lawns, a sour, mossy lawn may be much improved by an application of 5 cwt. of ground lime per acre. A month later Peruvian Guano at the rate of 3 cwt. per acre would assist the grass to form a thick growth.—COLIN RUSE.

Pinks from Seed.—A few years ago I filled a large border with plants of *Dianthus Heddewigii*. The plants were so satisfactory that I have always favoured them since. They were raised from seeds sown in gentle heat in the spring of the same year in which they flowered. About ninety per cent. of the blooms were double, the variety of colours wide, embracing some of the richest dark crimsons, and many were pure white. Seeds should be sown in boxes now, and the latter placed in a warm frame or on a greenhouse shelf. When the seedlings are large enough to transplant, they must be transferred to a sandy bed, or in such compost in boxes in a cold frame. Allow a space of 2 inches between the seedlings. From the frame the young plants must be shifted to their flowering quarters and be put out a foot apart each way. In the meantime get the soil in the bed deeply dug and well manured, and then the plants will not only grow freely, but continue to flower until the middle of November.—B.

Perpetual-Flowering Carnations for Bedding. Apparently Mr. E. Harriss, whose note on this subject appears in a recent issue, has been chary of testing many varieties of this type in the open. In a recently published election the fact was disclosed that no fewer than eighty-nine varieties have been proved to do well out of doors. *Britannia* is unquestionably the finest of all for the purpose, but one may safely plant all except the very large varieties. Some sorts, of course, are apt to take rust when grown in the open, and for this reason *Carola*, for one, should not be used outdoors. I have had grand flowers of the *Enchantress* group, *Baroness de Brien*, *May Day*, *Canary Bird*, *Wivelsfield Wonder* and *White Wonder*; but the large, full flowers are apt to suffer if we get a wet season like the last one. Border varieties, however, often fail to open in bad weather unless protected, and if one has to ward off wet from border varieties, one can also do the same with Perpetuals, and be sure of getting more flowers. I am inclined to think that many will adopt the policy of growing Perpetuals under pit-lights during the summer months. Supported on light framework, with the sides fully open, one could use the idle pit-lights to advantage. Protected from rains in this way, there is no reason why amateurs should not get flowers fit for showing during the summer; indeed, one amateur to my knowledge won a first prize last summer with a dozen blooms, several of which were cut from the open. *Royal Purple*, he informed me, is very fine for the open ground. A gardener near me has for several seasons planted out his

old stock plants, and he cuts flowers by the armful.—T. A. W.

***Narcissus triandrus albus*.**—When well established this is one of the most exquisite little bulbous plants obtainable. It appears to greatly resent disturbance, especially if this is accompanied by a drying off of the bulbs in the orthodox style. Three years ago I planted a dozen bulbs in a pocket of my rockery in very gritty loam, and they have now established themselves in a most satisfactory manner. The first season they produced the usual rather weakly stems with one or two flowers on each; last year two bulbs threw up stout stems bearing five fine flowers each, and one produced a six-flowered truss. As I allowed them all to seed—some fertilised by their own pollen, others by Mme. de Graaff—I feared this would weaken the bulbs for this season. On the contrary, they are finer than before, and I have just counted trusses of four flowers on two plants, of five flowers on five plants, six on one and eight on another. The individual flowers are very large, but have not quite the substance of *N. t. calathinus*. My bulbs have received no special care. The surface of the soil is covered with a thin layer of gravel, but I have not risked planting any dwarf plant above them. They face south-east, so get well ripened in the summer. I believe this is generally considered rather a weakly species and difficult to establish, so I hope this note will induce others to give it a trial. I should much like to know the greatest number of flowers that *N. t. albus* has been known to bear on a single stem.—NORMAN G. HADDEN, *Malvern*.

About Apple Blossoms.—Scarcely anyone, I think, would contest the assertion that one of the most beautiful pictures of natural beauty in early spring is the Apple tree laden with its chaste and pleasantly fragrant bicolored flowers. But not every admirer of the picture has noticed that there are three or four distinct shades of the two predominating colours, pink and white; hence this brief note of impressions respecting a few well-known varieties. Potts' Seedling, salmon pink; Lord Suffield, deep pink, one of the most striking; Worcester Pearmain, pale salmon, quite distinct, no other variety being quite like it so far as I have noticed; King of the Pippins, pale pink; Beauty of Kent, an average pink and white; Warner's King, rosy pink; and Cellini Pippin, inclined to salmon. These sorts afford the most striking contrasts out of the varieties I have been able to watch, and the colour tints noted apply to the early life of the flowers only, for after a certain stage they have a tendency, like all flowers, to lose their pristine beauty. Here and there one comes across a pure white petal among the clusters, as if it were an oversight on Nature's part, for assuredly it is the exception and not the rule. In Warner's King I have seen more white petals than in any other sort. But the one fact out of this study which seems of unusual interest is this: Apple Lord Suffield when ripe is a strawy yellow shade, but it produces one of the brightest of flowers; while Worcester Pearmain is a brilliant red fruit that has been preceded by a pale salmon flower. Of course, flowers vary in shade somewhat, grown in different soils, just as do the fruit.—C. TURNER.

ORNAMENTAL FLOWERED CHERRIES.

ALMOST throughout the *Prunus* family the various species are famous for their floral beauty, and as each one opens its blossoms it adds a distinct charm to the garden. Fortunately, many of the best kinds blossom in succession, therefore a continuation of beautiful effects is obtained from early March until late May. In March the Almonds attract attention; about the end of the same month the Myrobalan or Cherry Plum is a cloud of white blossom; April sees the double-flowered Peaches covered with red, pink or white flowers; during the latter half of the same month the Cherries commence to bloom, and before their beauty is gone the blossoms of the Bird Cherries expand.

The Cherries form a distinct group of the genus *Prunus*, and are sometimes known by the generic name of *Cerasus*, a name which is used by botanists to distinguish the well-marked Cherry group of the Plum family.

Prunus Avium is its best-known example, for it occurs wild in woods in some parts of the British Isles, where it is known by the common names of Gean and Mazzard. It is the parent of many of the cultivated Cherries, and in a wild state averages 40 feet to 50 feet in height, with a trunk 1 foot to 1½ feet in diameter. Much larger trees are known, however, for on the Cobham Hall Estate in Kent there are specimens over ninety feet high. On woodland trees peculiar, stiff, besom-like growths sometimes occur, the stems below them being enlarged by curious gouty swellings. Such growths are familiarly known as Mare's Tails, and are said to be caused by irritation brought about by the presence of a fungus (*Exoascus cerasi*). As a decorative garden plant the form with double flowers, known under the varietal name of *flore pleno*, is the best, and when every branch is laden with pure white, pendent blossoms it creates a most charming picture. Fortunately, it is amenable to general cultivation, and there are few places where it may not be expected to thrive. In course of time it forms a large tree, although it blossoms freely from the time when it is but a few feet high. There are other distinct varieties, of which *pendula*, with weeping branches and single white flowers, is very distinct. *Decumana*, which has very large leaves, is also a distinct and showy form, but the remaining varieties are no improvement on the wild tree.

P. acida is a small European tree with a dense head of branches. The white flowers appear with great freedom during early May. There are many varieties, several of which are well adapted for quite small gardens, for they never form large trees and are of compact growth, blossoming freely from the time when they are but 1 foot or 2 feet high. *Dumosa*, *humilis*, *Marasca* and *umbraculifera* are representatives of these varieties. The variety *semperflorens* is very different from the other forms. Of taller and looser habit, its branchlets are of a semi-pendent character, while the white flowers are borne in loose racemes in May and again in the summer. It is called the All Saints' Cherry, and it is an interesting and showy subject.

P. Cerasus is the dwarf Cherry or Morello Cherry, a European species which is also found wild in the British Isles. It is a free-flowering tree of smaller growth than the common Cherry. It

also has a double-flowered variety which is known as *Rhexii flore pleno*. Although a very showy tree, it lacks the grace of *P. Avium flore pleno*.

P. japonica is better known by its double-flowered varieties *flore albo pleno* and *flore roseo pleno* than by the type. The typical plant is of comparatively recent introduction, for seeds were sent from China to Messrs. Veitch early in the present century. The double-flowered kinds have, however, been known for many years, and the one with white flowers has been used for a long period both for beds and for forcing. Those with double flowers are still the most useful garden plants, although both the white and red forms

between the two species and their respective varieties, which have been cultivated and improved for a long period by Japanese and Chinese gardeners. Both are apt to form low trunks clothed with long, gaunt branches, which, instead of being furnished with long, slender branchlets, are thickly beset with short, stiff, spur-like growths, which are so prolific of flower-buds that each branch forms an inflorescence in itself, being clothed with flowers from end to end during April or May. Many of the varieties have double flowers, which are up to 2 inches across, and may be white, pink, rose or yellowish in colour. The chief difference between the two species is said

ROSE-GROWING IN POTS IN CONGESTED DISTRICTS.

THE writer has generally found that where difficulties abound in the cultivation of the Rose the more ardent the enthusiast becomes, and the well-known incident related by Dean Hole in his very racy Rose book of the mechanic who robbed his bed in order to keep the frost from the Roses may well be accepted as an example of this enthusiasm among the artisan class in our mining districts.

The object of this article is to give a few hints to readers who are compelled to reside in smoky or manufacturing districts and who desire to grow a few good Roses. To attempt this in the natural soil seems hopeless. How, then, can one proceed? I suggest growing the plants in pots in a cold frame covered by glass lights, or in an unheated greenhouse. Now there are individuals who expect the impossible. They are not content with having the well-known established favourites, but they cast their eyes longingly to the newer sorts, and if they fail they blame the nurseryman. Such individuals, moreover, are not content with obtaining good blooms, but they want to produce flowers equal to silver medal blooms as seen at the National Rose Society's shows. I would advise such enthusiasts to go in for the well-known established sorts and grow them well, and I can promise them unlimited enjoyment in so doing.

It should be clearly understood that a Rose plant cannot endure being prematurely forced into growth until its roots have become well established in the pot. It is in this that many failures occur. Amateurs purchase Roses from the open ground and pot them up in October,

and they expect such plants to be fit to put into the forcing-house in December and to be in bloom in March. This would be quite contrary to the usual procedure or to the nature of the Rose plant. If any reader desires to grow pot Roses in heated structures, I would advise him to purchase plants that are already established in their pots, or else to pot some open ground plants himself and grow such plants in the open and in a cold frame in winter, or to keep them entirely in the open garden for one summer and autumn following their potting up. This advice was given to a gentleman in Lancashire a season or two ago, and he writes to say he is delighted with the result.

Supposing this system be adopted, the plants should be pruned back to a foot at the time of potting, and their roots trimmed back if very long. Use a good compost consisting of turfy loam two parts, well-decayed manure one part, and a 6-inch potful of bone-flour to two bushels of compost, all well mixed together. Eight-inch pots are the best size to use. When potted, give the plants a good watering and then stand them in the open, the pots plunged in ashes up to their rim. Leave the plants here all the winter, covering them with mats, arranged over a wooden frame,

FLOWERING SPRAY OF PRUNUS CERASUS RHEXII FLORE PLENO, A BEAUTIFUL DOUBLE-FLOWED CHERRY.

with single flowers produce red fruits during the summer. Growing from 3 feet to 4 feet high, the double-flowered kinds are improved by a vigorous pruning every second or third year, for by that means strong young shoots are encouraged which produce the maximum number of flowers. Layered branches form the most rapid means of increase. This species is found in China and Japan.

P. pendula, the Rose-bud Cherry of Japan, is a very beautiful tree when at its best, for during early April its long, slender, pendent branches are wreathed with pretty rose-tinted flowers, which in the bud stage are a very bright shade of rose. It is one of the few pendent-habited trees which reproduce themselves from seeds. It is, however, often grafted or budded upon stems 6 feet or 8 feet high. Unfortunately, it commences to grow very early in the spring, and flowers and young shoots are sometimes injured by inclement weather. It has been given a variety of names, two which are sometimes used in gardens being *Cerasus japonica rosea* and *C. pendula rosea*.

P. Pseudo-cerasus.—This is a Chinese and Japanese species of very decorative appearance. It is closely related to *P. serrulata* from the same countries, and a good deal of confusion exists

to be in the fact of *P. Pseudo-cerasus* having hairy leaves and *P. serrulata* glabrous leaves. The variety known as *Watereri* is included with the former species, and *flore luteo pleno*, *flore albo pleno*, James H. Veitch and others with *P. serrulata*.

P. Sargentii is closely allied to *P. serrulata*, but it has fewer flowered clusters of bloom and more coarsely serrated leaves. Originally raised in the Arnold Arboretum from seeds received from Dr. Bigelow, a further supply of seeds was received two years later in the same garden from Professor Sargent, who collected them in Japan, where it grows 80 feet high, but it only appears as if it will form a small tree here. The elliptic or oblong leaves are up to 3½ inches long, and the rose-coloured flowers are about 1½ inches across and produced from two to four together in small clusters.

P. subhirtella.—This is a very beautiful early flowering Cherry, which is usually at its best during the first half of April. It forms a round-headed tree at least 18 feet or 20 feet high, and bears delicate rose coloured flowers, each about three-quarters of an inch across, in profusion. Except that it is of upright habit, it very closely resembles *P. pendula*, the leaves and flowers being practically the same. It can be raised from cuttings, and grows fairly rapidly into a shapely tree. D.

if the winter is very severe, or the plants may be removed to a cold pit having just a glass light covering. The plants are pruned at the end of March if kept outdoors, or if in a frame, then in February. It is advisable to prune well back to within 5 inches or 6 inches of the base of the plants. If no cold pits are used, keep the plants where they are outdoors until May, when they should be placed more thinly in the beds, so that all new growths may receive abundant air and light.

It will be seen that we have overcome one difficulty in growing Roses in uncongenial districts, and that is as regards the soil. We have now to try to make them grow in the vitiated air, and to do this they must have daily cleansing of the foliage. Where only a dozen or two are grown, it would be a small matter to sponge the foliage every evening with some Jeyes' Horticultural Wash, well diluted. The plants will need to be looked over every morning to see that they are not suffering for want of water. It is a common error to water every plant that looks dry on the surface. This is a mistake. The safest plan is to tap the side of the pots with the knuckles or a wooden hammer, and if it gives forth a bell-like sound, then apply water in good quantity. As the plants develop and show buds, weak liquid manure should be given, and also again after the flowers have finished their summer crop. If the shoots are tied out symmetrically to small sticks, the plants may be formed into a more perfect shape. If well looked after, there should be a good display in the summer, and again in September; then the plants will be ready for putting into the forcing-house for the next winter. But there may be some readers who cannot boast of much garden, but can only manage a small frame. To such I would say obtain plants in October and pot up as previously directed; then place the Roses in the frame, leaving the glass light off until February unless severe weather sets in. The plants should be plunged in ashes up to the rim of the pot. Very little water will be required during the winter beyond the first good watering after potting, and, of course, the plants would obtain such rain as falls, unless the latter is too much, in which case the light may be put over the plants and well tilted at the back or side to admit air night and day. If possible, allow the frame to slope to the south, and see that it is in the sunniest spot available.

Prune the plants in February to within 4 inches to 6 inches of the top of the pot, and after this great care will be needed in order that the plants do not become frozen. If the weather is at all sharp, keep the light closed down and protect with mats or sacks stuffed with hay. A frame 6 feet wide by 4 feet long and 3 feet deep at the back will hold about twelve plants in 7-inch or 8-inch pots. Such a frame can be made of stout wood, or, if preferred, bricks may be used. I have even seen turf used to make the walls, with a narrow board lying on the top of the turf walls to support the glass light. Any handy-man could make such a frame, and certainly he could glaze the light himself. In a frame of this

kind the plants will break into growth very slowly, but this is all the better for them. When the longer days of April arrive, growth will be more rapid, and, of course, more water will be needed. Do not be tempted to apply all sorts of artificial manures. The plants require none of these. One teaspoonful of guano to a gallon of water may be given when the tiny flower-buds are seen, and it may be repeated once a week until colour shows in the buds. By this time the plants may need a little more room, for it is essential that the growths be tied out to small sticks in order that every leaf may receive full light, and also to preserve a well-balanced growth. Another small frame would be useful, or, failing this, a makeshift one with wooden sides and canvas top would answer the purpose. Here the forwardest plants could be placed. An important detail to remember is the washing of the glass frequently, and, in order to hasten growth, syringe the plants about three o'clock in the afternoon of a fine day and shut down the light.

After blooming, the growths that have flowered should be cut back to a good plump eye and kept well syringed; of course, they must not be allowed to suffer for the want of water. A little weak liquid manure will be helpful for the second growth, and the syringe should be freely used every sunny morning and afternoon. Give plenty of air now, but, in order to accelerate growth, the glass light may

cow-manure if available, using one-third of this latter to two-thirds loam. A few good varieties to start with would be Caroline Testout, Mrs. John Laing, Frau Karl Druschki, Ulrich Brunner, Captain Christy, Captain Hayward, Lady Ashtown, Betty, Laurent Carle, Mme. Abel Chatenay, Mme. Ravary, Pharisäer, Prince de Bulgarie, Mme. Leon Pain, Lieutenant Chaure, Countess of Shaftesbury, Lady Pirrie, Sunburst, Richmond, Liberty, Ophelia, Mme. Jules Grolez and Mrs. Aaron Ward.

DANECROFT.

FOTHERGILLA MAJOR.

THOUGH this attractive North American shrub is figured in the *Botanical Magazine*, t. 1342, published in 1811, it must have disappeared from gardens soon after that date. For its reintroduction we are indebted to Professor Sargent, who sent it to Kew in 1902, plants having been found on the Alleghany Mountains. The Fothergillas belong to the Hamamelidaceæ, and are allied to the Parrotias and Hamamelis. There is another species cultivated in gardens, *F. Gardenii*, which name is synonymous with *F. alnifolia*. Both species flower during April and May; but in point of beauty the last named cannot be compared with the subject of the illustration. When first introduced it was named *F. alnifolia* var. *major*, and

FLOWERING SPRAY OF FOTHERGILLA MAJOR, A RARE HARDY SHRUB NOW BLOOMING AT KEW.

still be kept on, tilted, of course, during the day-time. It is a good plan to take each plant out once a week, lay it on its side and give it a good spraying, so that no insect foes lurk beneath the foliage. Green fly will show itself, and I know of no simpler remedy than Auto Shreds. They are simply set light to, and cause no trouble whatever. If the reader possesses a greenhouse and desires to plant Roses therein, he could not do better than plant out such pot Roses as I have described, or, if preferred, he can purchase established plants. The soil that will be used for the Roses in the planted-out greenhouse should be good loam—and it will pay anyone to import a cartload or two of good material—with some

was known as the Broad-leaved Fothergilla. The Fothergillas have no petals, the showy inflorescences being due to the bunches of creamy-white filaments. These appear in advance of the leaves, which are roundish oval, up to inches long. In autumn, as the leaves die off they assume a rich, clear yellow, lasting, as a rule, in beauty for several weeks. A plant growing at Kew is already about 4 feet in height. In the Arnold Arboretum there is a beautiful specimen 8 feet high. Six to a dozen plants make a very attractive bed or group along the front of a border of choice shrubs. Fothergillas thrive in a compost of sandy loam, peat and leaf-mould. Layering and cuttings form ready means of increase

SOME BEAUTIFUL POPPY-WORTS.

THE MECONOPSES.

(Continued from page 216.)

Cultivation.—A point of high importance here is that for all practical purposes the plants are moisture-loving, preferring peat, leaf-mould and loam in about equal parts, while not objecting to rich, light loams alone. Equally important, for some species at least, and those of nobler growth more particularly, is the question of soil richness; hence too great a proportion of peat should not be employed, or, if for any reason employed, it must be liberally enriched. In this connection no words of mine could possibly possess half the weight or importance of those which, in response to questionings as to the exact conditions under which he found the unique *M. integrifolia*, came from the lips of Mr. E. H. Wilson. In the first place, he said the whole of the cultivated examples he had seen since his return had been extremely disappointing, giving the impression of starvelings rather than that of well-grown specimens. In its high mountain home, he further remarked, the ground is traversed by vast numbers of yak, a species of ox, which are responsible for the heavy manuring of the ground. To these conditions Mr. Wilson attached the great vigour of the plants, the richer colouring of the flowers, and the greater freedom of production; hence it would be well for gardeners generally to cultivate the plant on these lines. Mr. Wilson was also emphatic as to the hardiness of this fine species, and imagined that the feeble results he had seen were, partly, the evidences of fear on the part of the cultivator rather than those of indifferent treatment or neglect.

We know to-day that not a few of the more robust-growing species not only delight in rich soils, but that the cooling effects of cow-manure have a decided influence for good in the maintenance of a steady, continuous growth. How great a part altitude and the rarefied conditions of high mountain air play in the cultivation of these plants must ever remain a mystery. Even if solved, the information, because of the impossibility of imitation, would be quite useless to the gardener. The task before the latter is that of adapting these children of the mountains to the conditions prevailing in lowland countries, and in so doing he will find the school of experience—observation and experiment—of the greatest possible service.

Though the fact that the major portion of the species comprising the genus are virtually only of biennial duration is well known, it is worth repeating, if not, indeed, emphasising. Biennial plants of all classes, if they are to produce at flowering-time the best they are capable of giving,

must be so raised from seeds and subsequently planted in their permanent quarters as to render possible the fullest development of the plant in the first year. Failing this a meagre development results, and all else—size, colour, free and profuse flowering—follows in due proportion. Of no group is this more true than of these biennial Poppyworts. In other words, a spring sowing of the seeds cannot produce the results of an autumn sowing, any more than July planting can equal that of April or May.

Seeds and Seedlings.—Seeds are not always produced abundantly or of the highest quality. This is so even in those instances where artificial pollination has been resorted to. Apparently

tion of the earlier opening flowers is resorted to, a moderate supply of seeds will be forthcoming. These may be sown at any time within a month or so of harvesting, and, if of good quality, will vegetate in about three weeks thereafter. Well-drained pans of light, sandy loam or sandy peat will do quite well for the seed-sowing, and the seeds, covered with soil of the thickness of half-a-crown, will be quite safe in the temperature named. A cultural item of importance is that the soil of the seed-pan be well soaked with water in advance, so as to reduce to a minimum any further need for water till the seedlings appear. This latter may be expedited by covering the seed-pans with sheets of glass, and again with moss, to conserve moisture and the uniform conditions of soil warmth. Subsequent treatment resolves itself into pricking off and potting singly as occasion demands, and in maintaining a sturdy, uninterrupted growth by further shifts till the arrival of April, when the plants should be ready for their permanent places in the garden. E. H. JENKINS.

(To be continued.)

IRIS FLAVESCENS, A BEAUTIFUL MAY-FLOWERING HYBRID WITH YELLOW BLOSSOMS.

A CHARMING MAY-FLOWERING IRIS.

IRIS FLAVESCENS.

THIS attractive May-flowering Iris is worthy of extended cultivation. For some unknown reason it is very much neglected, and is, like the German Iris, more often than not relegated to an out-of-the-way corner in the garden, where it is allowed to dwindle and die. *Iris flavescens* is a good border plant; the flowers are yellow, and the plant attains a height of 2 feet to 3 feet. For a long time it has been looked upon as a synonym of *I. imbricata*, but Mr. W. R. Dykes, in his thoroughly reliable book, "The Genus Iris," says "the frequently repeated statement that *I. flavescens* is a native of the Caucasus is due to its erroneous identification with *I. imbricata* (Lindl.). It is doubtless a garden hybrid and has no real claim to specific rank." Whatever may be its origin, *I. flavescens* is a beautiful Iris of the easiest possible culture. Two conditions are essential to its welfare, *i.e.*, sun and a well-drained soil. It will thrive in both heavy and light soils; but if the soil is very sandy, a top-dressing of short, well-rotted manure and leaf-soil will prove beneficial. When transplanting is necessary, it should be done soon after flowering.

NEPETA MUSSINH.

It is a good plan to plant this lovely perennial in a border of Roses. It serves to cover up bare stems, and will be found to associate well with almost any colour. Last season we saw this combination on a large scale, and we shall not readily forget the effect. It should be planted without delay.

large quantities of good seeds are produced, the thin crop of resulting seedlings demonstrating either the infertility of the majority or some cultural error in raising them. In this connection I am of opinion that cold-frame treatment may, to some extent, be responsible, the seeds perishing in the soil, and that a quicker germinating, the outcome of sowing in slight warmth, say, a temperature of 45°, would be more productive of good results. In the case of *M. integrifolia* and *M. Wallichii* this is undoubtedly true, and there may be others. The only way to ensure a good crop of seeds is by artificial pollination, and, even so, much depends upon the season and not a little upon the fecundity of the pollen. Usually, however, where pollina-

PLATE 1493.

FOUR GOOD ANTIRRHINUMS.

MOST of our readers will remember that last year the Royal Horticultural Society held a trial of Antirrhinums in the famous gardens at Wisley. There a great many varieties were grown side by side for comparison, and when judged a number were granted awards of merit. Four of the varieties thus honoured are shown in the accompanying coloured plate, which, owing to the wide range of colours, does not quite adequately portray the vivid hues of the flowers. Coccinea was sent to the trials by two firms, viz., Messrs. Dobbie and Co. and Messrs. Dickson and Robinson. It is a beautiful variety, and creates quite a brilliant effect in the garden. Rosy Morn was also sent by Messrs. Dickson and Robinson and by Messrs. Watkins and Simpson. It is a beautiful shade of pink, and the plant has a nice sturdy habit. Golden Queen was sent by three firms, viz., Messrs. R. H. Bath, Limited, Messrs. Dickson and Robinson, and Mr. W. H. Simpson. It has large flowers that are well placed on stout, erect stems. Maize Queen, the fourth variety, is officially described as maize yellow. This also was sent to the trials from three sources, viz., Messrs. Dobbie and Co., Messrs. J. H. Veitch and Sons, Limited, and Mr. W. H. Simpson.

The cultivation of Antirrhinums was fully dealt with by Mr. R. P. Brotherston in the issue for March 14 last, so that it is not necessary to describe it in detail here. They are not difficult plants to grow, and, although it is too late to sow seeds now to provide plants to flower this year, sturdy seedlings can be purchased from many nurserymen and plant growers. These are usually ready for moving about the third week in May. Seed may be sown outdoors during June to provide plants for flowering early next year, and where it is desired to naturalise Antirrhinums in old walls or rockwork, that is undoubtedly the best course to pursue. For beds and borders, however, early spring sowing in frame or greenhouse usually gives the best results. With the many beautiful colours that we are now getting in modern varieties, it will not be surprising if, in a few years' time, they become almost as popular as the Sweet Pea.

SOWING WALLFLOWERS.

SEEDS of these indispensable flowers should be sown at once in order to obtain good strong plants for the flower garden in October. Sow the seeds in shallow drills a foot apart, and transplant the seedlings as soon as large enough to handle. Other seeds for spring bedding should also be sown now, and these may include Myosotis, Pansy, Polyanthus, Silene, Aubrietia, and double Daisy New Giant Rose and White.

RHODODENDRON ROSY BELL.

ALTHOUGH Rhododendron Rosy Bell is by no means new, yet it is only within the last year or two that its merits have been appreciated. As an early variety for Southern gardens it is coming rapidly to the fore. The parents of this attractive hybrid are two Sikkim species, *R. ciliatum* and *R. glaucum*. For outdoor decoration it is a most useful plant, but, as may be imagined from its parentage, not very hardy. Except in the favoured South and West, a position sheltered from the morning sun should be selected when planting, so that if there is a little frost it will gradually thaw before the sun's rays reach the plants. The flowering season is the second half of April. The plant is evergreen; the blooms are bell-shaped, about an inch long and the same in width.

A GROUP OF THE BEAUTIFUL RHODODENDRON ROSY BELL.

They are borne in small, rather loose trusses, terminating practically every twiggy growth. These usually consist of about five flowers, while sometimes there are two or three trusses together terminating a growth, which to all intents and purposes might be one large truss of flowers. The colour is a delicate pink with a suspicion of mauve.

As can be readily seen in the accompanying illustration, Rosy Bell is a dwarf bushy plant and very free flowering. With age the plants gradually increase in size, the tall plant in flower at the back of the group being also Rosy Bell. It is quite a good plant for the rock garden as well as for the border, while those who have only a bleak garden will find Rosy Bell a useful Rhododendron for pot cultivation. Cuttings root readily in sandy peat under a bell-glass, and in a propagating-frame with slight bottom-heat.

DAFFODIL NOTES.

NEW DAFFODILS AT THE ROYAL HORTICULTURAL SOCIETY'S 1914 SHOW.

IN dealing with novelties I need only say by way of introduction that there were only a very few which I might describe as altogether "out of the way." The double Llinos marked a new type of double of a symmetrical and pleasing shape, and was the most talked about flower in the hall. A magnificent Lucifer, shown by Mr. A. M. Wilson under a number, is as large as any, if it is not the largest flower, with a long all-red cup and white perianth. Before dealing with the different items in detail, I think I ought to explain the meaning of my measurements. It will have been noticed that I usually use such a formula as $3\frac{1}{2}$ inches \times $1\frac{1}{8}$ inches

or 4 inches \times (1 inch \times $1\frac{1}{8}$ inches) \times ($1\frac{1}{8}$ inches \times $2\frac{1}{8}$ inches). In both cases the first number is the diameter of the perianth. Where only a single measurement follows, that one is the diameter of the eye or cup. The inference to be drawn is that the flower is a Poet or a very shallow cupped variety of some Barrii or Leedsii. Where two measurements follow, the first is that of the exterior segments of the perianth (the first that of their greatest width and the second that of their length from the base of the corona or trumpet to the tip) and the last one that of the trumpet or cup (the first being the length and the second the diameter of the top, including the recurve of the brim). I hope this short explanation is clear, for, as the late Mr. Sydenham used to say, these details enable us to construct the flower in our mind's eye.

Llinos, a new type of double raised and shown by Mr. Watts of St. Asaph. This was the first bloom on the plant, so there is just a little doubt

if it will come the same again, although the raiser has every hope that it will. The flower has a diameter of 4 inches, with two regularly placed rows of perianth segments on the outside, with parts of the split-up corona symmetrically arranged between them. The centre of the whole is a jumble up of longer and shorter bits of either petals or corona, two or three of the pale shaded ones being especially prominent. Perianth primrose; the petals of the inner row have a yellow stripe down their centre. Corona pale orange.

Lord Lister (Welchman), an exquisite white Ajax, which I remember was exhibited at Birmingham last year. As the measurements indicate, it is a flower with a trumpet on the short side, the recurve of which is a little like that of Mme. de Graaff. The perianth segments are smooth and overlapping, with just the slightest inclination to come forward. It was certainly one of the best flowers at the show. Size: $4\frac{1}{8}$ inches \times ($1\frac{1}{2}$ inches \times $1\frac{5}{8}$ inches) \times ($1\frac{1}{2}$ inches \times $1\frac{7}{8}$ inches).

Martel (Cranfield), a giant incomparabilis of perfect symmetry and form, the whole flower of a rich yellow, with the cup or small trumpet of a deeper shade. The perianth is perfectly flat, and is set at right angles to the corona. The segments are wide and overlapping. It is a true florist's flower, and stands to the usual giant incomparables much as Florist's Favourite, which I described in the issue of April 25. and of which an illustration is given on this page, does to an ordinary trumpet, such as Golden Spur or Emperor. Measurements: 4 inches \times ($1\frac{3}{8}$ inches \times $1\frac{5}{8}$ inches) \times ($1\frac{3}{8}$ inches \times $1\frac{5}{8}$ inches).

Princess Juliana (Barr), a rich, very deep yellow Ajax, a real self. Its distinguishing feature is the massive, widely scalloped recurve of its somewhat short trumpet. It is a flower that one is bound to notice in any collection—perhaps this is why it is called after the little girl Princess of Holland—otherwise I would have thought its sturdiness would rather have suggested a William the Silent or a Barneveldt. It received an award for show from the Narcissus committee. Measurements: $4\frac{1}{4}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{3}{4}$ inches) \times ($1\frac{1}{2}$ inches \times $2\frac{1}{8}$ inches). N.B.—When the diameter of the trumpet (here $2\frac{1}{8}$ inches) is very much in excess of that of its length (here $1\frac{1}{2}$ inches), it usually denotes a wide recurve of the brim.

Morven is a pale bicolor Ajax which was raised at Forres Castle by Brodie of Brodie. It was brought before the committee by Messrs. Cartwright and Goodwin, and received an award for show purposes. It is a very cool, clean-looking flower, and has a decided resemblance to J. B. M. Camm in its general appearance, but with a longer trumpet. Size: $3\frac{3}{4}$ inches \times ($1\frac{1}{4}$ inches \times $1\frac{1}{2}$ inches) \times ($1\frac{5}{8}$ inches \times $1\frac{1}{2}$ inches).

Sigismund (Barr) resembles a beautiful Giant Leedsii, with very broad, overlapping segments of great substance, the whole flower being of a delicate greenish white. Size: $3\frac{1}{2}$ inches \times ($1\frac{1}{2}$ inches \times $1\frac{3}{8}$ inches) \times ($1\frac{1}{8}$ inches \times $1\frac{1}{8}$ inches).

White City (W. T. Ware) is a striking Leedsii of the White Lady type, raised by Mrs. Backhouse. The perianth, which is of a beautiful white shade, is inclined to come forward and the extreme edges of the petals to incurve. Massed as Mr. Ware had it in great market bunches, "it was

fine." Size: $3\frac{1}{2}$ inches \times seven-eighths of an inch. It is a very thick flower.

Ivory King (Bourne) must have been, I fancy, a new purchase, for its name does not occur in the 1914 list. Anyhow, Mr. Bourne annexed a great beauty when he bought Ivory King. It is away from the usual shades of large Ajaxes, inasmuch as it is a rich ivory white self. The perianth is slightly hooded, and the trumpet wide and boldly expanded at the brim, the whole bloom being of much substance. Measurements: $4\frac{1}{2}$ inches \times ($1\frac{5}{8}$ inches \times $1\frac{3}{4}$ inches) \times ($1\frac{3}{4}$ inches \times $1\frac{7}{8}$ inches).

Coral Queen (Barr) is a white-petalled Barrii. The segments are rather "rough" and uneven, but not so much as to prevent it being a beautiful flower for vase decoration. The broad band of

THE NEW DAFFODIL FLORIST'S FAVOURITE. THE RICH, DEEP YELLOW FLOWERS ARE OF PERFECT FORM.

rosy buff which circles the flat eye is most uncommon, and will well repay any little extra trouble that an early gathering and afterwards keeping of the blooms would occasion. It is no use disguising or minimising the fact that these delicate and fugitive colours need special care if we are to enjoy them, and that treated as an ordinary garden plant, like an Emperor, they are never seen. Size: 3 inches \times seven-eighths of an inch.

Golden Apricot (Barr) is another example of a flower with unique colouring in its cup, which, as the name implies, is a golden apricot with an edge of buff; at least, that is the best Mr. Rudolph Barr and myself could do as we stood before it and discussed its shade. The cup is large in proportion to the whole. The perianth is rough and of much substance. Size: $3\frac{1}{2}$ inches \times (1 inch

\times $1\frac{3}{8}$ inches). The numbers in parentheses belong to the cup.

Mogador (Engleheart) is an exquisite example of a star-shaped Giant Leedsii of great refinement. It features in many respects White Pennant (R. H. Bath), but the cup is much more like a diminutive trumpet. As White Pennant was in the hall, I was able to compare the two varieties together, and as a result I fell a victim, and the next time it blooms some of the bulbs will find themselves in New Zealand and some at White-well. I call it Mogador, the lovely white city on the seashore of the Atlantic as seen from the surrounding sand hills, the southernmost port of Morocco open to foreigners. Size: Diameter of the whole flower, 4 inches. I do not seem to have any record of the cup, but it must have been about $1\frac{1}{2}$ inches \times $1\frac{1}{2}$ inches.

14 R 5 (Engleheart) is a narrow-cupped Leedsii of striking appearance because of the pink edge to its cup. It has a perianth like that of Thora, and a long, rather narrow cup, broadly suffused pink. It is seen to most advantage when the flower is held sideways against the light.

741 (Wilson) is the magnified Lucifer which is previously referred to. Size $4\frac{1}{8}$ inches \times ($1\frac{1}{2}$ inches \times $1\frac{1}{8}$ inches) \times (three-quarters of an inch \times seven-eighths of an inch). In estimating this measurement I ought to say that I think the diameter ($4\frac{1}{8}$ inches) would have probably been a quarter of an inch more if the segments had been stretched to their full length.

Martha (Wilson), a refined small flower of a lovely shade of primrose, both perianth and corona being an exact match of one another in colour, a well-defined edge of red round the cup giving the necessary relief. Size of bloom: $2\frac{3}{8}$ inches \times seven-eighths of an inch.

Yellow Poppy (Cartwright and Goodwin) is a very large incomparabilis, with a wide open, cup-shaped corona in the place of the more usual long-shaped one. The perianth was flat and overlapping, with rounded segments, and pale primrose in colour. The yellow cup was edged with a narrow band of orange. Dimensions: $3\frac{3}{4}$ inches \times ($1\frac{1}{2}$ inches \times $1\frac{1}{2}$ inches) \times (three-eighths of an inch \times one-eighth of an inch).

Various.—I have many more nice flowers described in my notes, such as the most exquisite triandrus hybrid with which Mr. P. D. Williams won the single bloom class; Mont Clair, a grand, very deep yellow Ajax on Messrs. Barr's stand;

the well-grown Harold Finn and the single bloom of White Pennant on Messrs. Bath's; Girdle, one of Mr. Watts' fine Giant Leedsii; Agatha, a pretty pointed white Ajax on Mr. Bourne's; the chaste white trumpet Vestal Virgin on Messrs. J. R. Pearson and Sons', surely one of the most lovely of its type; and a uniquely coloured one also among Messrs. Pearson's, with a primrose perianth and a lemon trumpet, named Sulphur Gem— $3\frac{3}{4}$ inches \times ($1\frac{3}{8}$ inches \times $1\frac{1}{2}$ inches) \times ($1\frac{1}{4}$ inches \times $1\frac{1}{4}$ inches)—sold to Holland, that country so greedy for our beauties and so successful in getting them; Mrs. W. O. Wolseley, a very early and refined Giant Leedsii on Messrs. Carter's; and others too numerous to mention, which is just as it should be, seeing that I am writing about the big London show of 1914.

JOSEPH JACOB.

GARDENING FOR BEGINNERS.

HOW TO GROW VEGETABLE MARROWS.

THE Vegetable Marrow is a prolific plant when well treated. It is a fact, however, that the best is rarely obtained from the plants. After the first week in June they grow freely in suitable soil, but perhaps it is owing to the ease with which they can be grown in warm weather that many cultivators pay less attention

to the welfare of the plants than their merits as luscious vegetables warrant. On the other hand, there are cultivators who are over-anxious in the matter, and raise seedlings too early, coddle the young plants, and put them out a few weeks too soon; then they get a serious check, if they are not quite killed. From start to finish Vegetable Marrows require warmth and to be guarded against chills.

Sowing Seeds.—If seeds are sown before the middle of May, the resultant plants will be ready to put out on June 10, a

date quite early enough, as young, robust plants are much more valuable than those stunted through being kept in the pots too long. Sow one seed in a 3-inch pot filled with loam, leaf-soil and sand in equal proportions. No. 1, Fig. A, shows how the seeds must be sown. It is a wise plan to sow them in fairly moist soil; then, if the pots are placed in a warm position, the seeds will germinate without being watered. But it is essential that the soil be kept moist, else germination will be delayed; furthermore, after it has started, the

embryo plant will perish if the soil suddenly becomes very dry at this season. A warm frame is the most suitable structure for the young plants until a fortnight prior to their being put in their summer quarters, and during that fortnight they must be retained in a cold frame, where they can be fully exposed in the daytime and partly so at night. No. 2 shows a plant in a 6-inch pot at a suitable stage for planting out.

Making the Beds.—In the meantime the cultivator must form the beds in readiness for the plants. It is a mistake to select a much-shaded position or one exposed to east winds. An open, sunny quarter is best. It is unwise to build up a high, dry bed of straw and put on it only a few small heaps of common garden soil. A solid heap of soil, weeds and other garden rubbish would be better. The best bed, however, is one similar to Fig. B. It is composed of rotted manure and good loam, with a free admixture of half-rotted leaf-soil, and is about a foot above the general level of the surrounding ground.

Planting and Training.—No. 1, Fig. B, shows the plant; Nos. 2, 2, side shoots; Nos. 3, 3, the side shoots stopped when several fruits have formed on each. The leading shoot need not be stopped at all, but be trained and pegged down on the bed, so as to fill up nicely all surface space without undue crowding. Allow a space of 5 feet from plant to plant.

Fertilising or "Setting" the Fruits.—Like Melons and Cucumbers, Vegetable Marrows bear male (staminate) and female (pistillate) flowers. In Fig. C, No. 1 denotes a male flower; No. 2, a male flower with half of the yellow flower petals removed. No. 3 shows the bared stigma. No. 4 represents the embryo fruit or Marrow, and No. 5 the stigma of the male bloom inserted in the centre. All cultivators of Vegetable Marrows do not go to the trouble of thus setting the fruits, but leave it to bees and other insects. Sometimes full crops are obtained thus; but it is well worth while, especially in dull, cold seasons, to artificially set the fruits. Water when it is needed, and feed liberally after there are a number of Marrows swelling nicely.

G. G.

THE HERBACEOUS BORDER IN MAY.

THE herbaceous border is once more alive with new growth in all directions, and with these significant and welcome signs before us arises the thought as to how best we can assist Nature to perform her perfect work. There are just at this time many duties requiring attention, among which is

Mulching.—The recent spell of abnormally warm weather will have perforce turned gardeners' minds to the expediency of mulching, even thus early in the season, and this is certainly advisable, as subsequent results will no doubt prove. For this purpose the manure need not be of the decidedly "old" type, recommended for use when digging in. It should not, however, be laid on in large "cakes," but be first well broken up with the fork, remembering that the object of a mulch is to prevent undue evaporation of moisture round the roots, while at the same time not obstructing air access. In the event of mulching material not being available (manure is not essential; grass

or hedge cuttings answer the purpose), the next best thing is to keep the top soil in a friable condition by frequent use of the Dutch hoe. As a matter of fact, keeping a permanently good surface tilth will always be found extremely beneficial to the plants, and especially during dry weather. In illustration of this point, a friend of the writer's places so much confidence in his Dutch hoe—with justifiable results—that he never uses a watering-can at all! And this garden is always "fair to look upon." We will now consider the question of

Thinning.—The present is an opportune time for reducing the number of shoots on such perennials as Phloxes, Delphiniums, Achilleas, and similar subjects. The weak, and therefore undesirable,

A.—SHOWING SEED SOWN IN POT AND SEEDLING WELL ESTABLISHED.

B.—MARROW PLANTS IN BED, WITH SIDE SHOTS STOPPED AFTER FRUIT IS SET.

C.—DIAGRAM TO ILLUSTRATE HOW TO FERTILISE THE FLOWERS.

shoots need to be removed, and frequently also a few stems from the centre of the plant, in order to allow the remainder room to develop. Next comes the necessary consideration of

Staking.—It is of importance that this duty be commenced early. Bamboo canes are excellent for the purpose. The aim in view should be to keep the plant growing in as natural a position as possible; hence large-sized plants may require several stakes. In tying, say, a plant of Erigeron, it will be found to be worth while not only to surround the whole with the tying material, but also to cross and re-cross it through the plant—this will tend to prevent crooked flower-stems.

B. W. L.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Fruits Under Glass.

Peach and Nectarine Trees in Late Houses require careful attention with respect to thinning and tying the young shoots. This is a very important matter, especially if the trees are young, for if they are neglected at this stage it is a difficult matter to make good trees of them afterwards. While tying in the young shoots, a space of 4 inches should be allowed between them. Choose the best-placed shoots of medium size, and remove everything which is not required for next season's crop.

Apple and Pear Trees in Pots.—Now that the fruits are swelling, these trees may be given a little more liberal treatment. Syringe twice daily, but never with sufficient force to injure the soft, young foliage. Water with great care, and when necessary give water in sufficient quantity to reach the extremities of the roots. Top-dress the pots with fine loam and a sprinkling of artificial manure.

Plants Under Glass.

Deutzia gracilis.—These plants may be cultivated in pots for a number of years, providing they are carefully pruned and thinned out after flowering. The plants should then be placed in a warm, moist atmosphere until the new growths are fully developed, when they ought to be removed to cooler quarters and gradually hardened and prepared for plunging out of doors.

Fuchsias.—Young plants raised from cuttings should now be ready for their final potting. The compost may consist of turfy loam, leaf-mould and cow-manure, with a good sprinkling of rough sand. Grow the plants in a warm, moist atmosphere, and use the syringe freely. If standards are required, strong, straight plants must be selected and neatly staked. All side shoots should be removed until the plant has reached the necessary height, when the top ought to be removed.

The Flower Garden.

Antirrhinums.—Plants raised from early sown seed will now be ready for planting in their flowering quarters. If distinct colours are desired, it may be necessary to examine the foliage of each plant to make quite certain it is of the proper type. For dwarf varieties a space of 12 inches will be sufficient between the plants, but for tall-growing sorts 18 inches should be allowed.

East Lothian Stocks may be planted out as soon as the plants are of suitable size, allowing a space of 15 inches between the plants. Water freely and make the soil firm about the roots.

Gladioli.—If these have been forwarded in pots, no time should be lost in placing them in their flowering quarters, making the soil as firm as possible about the roots without breaking the ball of soil in which they have been started into growth. As soon as the flower-stems are of sufficient height, secure them to a strong stick.

Shrubs.—Late-planted shrubs should be freely watered during dry weather and the stems syringed late in the afternoon. A mulching of decayed manure may be applied with advantage previous to watering with clear, soft water.

Plants for Summer Bedding.—Pelargoniums, Fuchsias, Heliotropes and all plants intended for summer bedding ought to be removed to cooler quarters and prepared for planting in the flower-beds when the proper time arrives. During the next few weeks it will be necessary to examine the plants several times daily, in order to avoid injury from want of moisture at the roots.

Sweet Peas.—A sowing may be made now for the supply of blooms during August and September. If sown in the open, the soil should be thoroughly prepared before the seeds are placed in the ground; but if pots and space are available, the plants may be raised under glass and planted out when sufficiently advanced.

The Hardy Fruit Garden.

Mulching.—There should be no delay in mulching recently planted fruit trees. This ought to be accomplished before watering. It may be advisable to leave one or two fruits on recently planted trees in order to test the variety, but nothing beyond this should be attempted the first season, or the trees will become stunted, and may be permanently injured in consequence.

Strawberries.—The protection of Strawberry flowers from frost is an important matter, especially in low-lying districts. On early borders it is an easy matter to cover the plants with blinds, which should be available in all gardens where early fruits are expected. In the open garden considerable protection may be afforded by placing a quantity of dry stable litter loosely between the plants; this will protect them from cold wind, and, in the event of frost, may be lightly sprinkled over the foliage. It may eventually be used to mulch the bed and protect the fruits from splashing by heavy rain.

The Kitchen Garden.

French Beans.—Plants in pots from which supplies are being gathered will not require much fire-heat, but should be well supplied with manure-water. Syringe the foliage twice daily, or red spider may prove troublesome. Plants in heated pits ought to be freely ventilated, and the bed should be thoroughly watered whenever necessary. Further plantations may be made in cold pits to afford supplies before they are available from the open garden.

Beetroot.—Early sown Beet in pits should be freely ventilated to keep it from becoming drawn. Allow a space of 6 inches between the plants, and water the bed freely with clear, soft water. Make frequent small sowings of Turnip-rooted Beet from now until the middle of July; these will prove useful during the summer and autumn. The principal sowing of long-rooted Beet may be made now.

Celery.—Continue to prick out young Celery plants on a sheltered border for planting in the trenches in June, and take the earliest opportunity to prepare the trenches so that the plants may be put out as soon as large enough. Water freely with soft, clear water, and damp the plants overhead until they are quite established in the trenches.

Royal Gardens, Windsor.

JOHN DUNN.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beet.—In most districts it is now quite safe to make the principal sowing, which in many instances is the only one. Sow in drills 1 foot to 15 inches apart and 2 inches deep in ground that has been well manured the previous season. Thin out as soon as the plants can be handled. I do not advise transplanting the thinnings, as, unless in very favourable weather, I have not seen them ever come to much. Where the seed has not come up well, it is much better to sow a little more seed in the blanks. These will come early enough to make nice, serviceable roots.

Turnips.—A larger breadth may now be sown, but avoid doing so in continual dry weather, which would assuredly be a source of disappointment. The better plan is to sow when there is a prospect of rain or immediately after showery weather.

The Flower Garden.

Planting Hollies.—In our Northern climate these may be planted from now till the beginning of June; indeed, I have seen large numbers of fine specimens moved up to the second week of that month, with the best results. Of course, with these, as with other choice shrubs, the planting will have to be done with the greatest care. If there should be any doubt of their suffering from the shift, go over them carefully and cut out a branch here and there where it will be least observed. This will ease the plant considerably.

Bamboos.—These graceful evergreens, which play such an important part in the beautifying of our gardens, may now be divided and replanted. Where one has difficulty in getting them to grow satisfactorily, it may be pointed out that they should be sheltered from the cold north-east winds and partially shaded. Should the natural soil not be quite suitable, this can be made good by taking out pits 2 feet deep and a sufficient width, and making them up with good garden soil mixed with some well-rotted manure. After planting, the plants should be well watered and mulched with some stable manure. With a suitable selection of hardy varieties, there is no reason why they should not thrive almost in any district.

Box Edges.—From now till the end of the month is perhaps the best time to have all Box edges clipped. It is, however, no uncommon thing to see this work being done as early as March. This is a great mistake, as if done so early in the season the plants are sure to suffer from frost, and present a whitened appearance.

Pansies and Violas.—Continue to pick the flower-buds off as they appear for some little time yet. This will enable the plants to become well established, and they will not be so likely to be affected by drought.

Border Carnations will be greatly benefited by a dressing of soot between the rows, and afterwards have the soil stirred with the Dutch hoe. This may be repeated during the growing season. Varieties of the King Arthur type, which produce little or no grass, should in a number of cases have the flower-spike pinched to induce the plants to break and produce grass for layering.

Plants Under Glass.

Primulas.—Where more than one batch of these serviceable greenhouse plants are required, a sowing may be made now. The compost should consist of equal parts of leaf-mould and loam, with the addition of a little silver sand. This must be pressed moderately firm in the seed-pan and watered some time previous to sowing. The seed should be sown very thinly, have the merest covering of fine soil, and afterwards be placed in the warmest part of the greenhouse.

Cyclamen.—The strongest of the young plants will now be ready for potting on, and must be kept near the glass to promote a sturdy growth. It is of the utmost importance that the young plants be kept free from aphids, as if allowed to get a foothold at this stage they never do much good. To keep them free it will be necessary to fumigate them frequently. Shade them during the hottest part of the day and pot on the remainder as they are ready.

Dendrobium nobile.—This beautiful Orchid, so easy of cultivation, will now be making its growth, and should have attention. Some of the plants will require potting, others top-dressing; but they should not be disturbed at the roots more than is necessary. Remove them to the warmest part of the plant stove, where they will get plenty of light, and, if they are established in baskets, they may be watered freely and syringed several times a day to keep down red spider and thrip.

The Hardy Fruit Garden.

Swelling Fruits.—As the fruits of all wall trees begin to swell, a good coating of manure should be placed round each tree, and, where at all possible, be given a good soaking. Continue to examine trees just set and reduce the bunches considerably. The practical man will have no difficulty in knowing which to retain.

Strawberries.—Plants in pots that have been moderately forced may be planted out in a prepared bed and well watered. These will often give a supply of fruit in the late autumn, which will be immensely appreciated. On account of the roots being matted together, the plants must be kept supplied with water during the season.

Fruits Under Glass.

Figs.—The fruit in the earliest house will be ripening, and must have less moisture and more air admitted. Trees swelling the fruit will require abundant supplies of water, besides frequent doses of liquid manure. Thin out and stop shoots to avoid overcrowding, as each shoot must be fully exposed to the sun to develop the next crop.

Vines.—There will be much to do in the vineries during the next few weeks. In the earliest house the Grapes will be colouring, and these will require abundance of air, while in succession houses the Grapes will be swelling and the latest varieties will now be breaking. Keep a sharp look-out for those destructive weevils which play such havoc with the foliage. Where they are troublesome, the best time to search for them is just as darkness is coming on. They will be found on the back wall, and if newspapers are placed under the rods, they can be caught by giving the rods a sharp tap, when they will fall into the paper. They should then be collected and destroyed.

JOHN HIGHGATE.

(Head-gardener to the Marquis of Linlithgow.)
Hopeloun Gardens, South Queensferry, N.B.

SEASONABLE NOTES ON AURICULAS.

THIS month the plants will be getting past their best, and the earlier-flowering varieties are nearly over. The flowers should be pinched off at the top of the truss and the stem allowed to gradually die and dry up, when it can be easily removed later on.

Repotting.—I always like to have the bulk of the repotting done during the month of May, and usually begin directly the plants have passed the flowering stage. The rooting medium should consist of the best fibrous loam three parts and leaf-mould one part, to which is added a sprinkling of sharp sand or crushed oyster shells. A 6-inch potful to every bushel of the mixture will be ample. Where the loam is of poor quality, a little decayed manure or bone-meal may be incorporated in the compost. This must not, however, be overdone, and for the benefit of the beginner I may state that a 4-inch potful of bone-meal to each bushel of soil will be sufficient; but with decayed manure, such as may be obtained from an old hot-bed, the careful grower is not likely to exceed the limit.

How to Repot.—Large pots are not required, and for fully grown plants I should select a receptacle about four inches in diameter, with, perhaps, a pot half an inch larger for exceptionally fine specimens. Smaller examples should be placed in pots just large enough to comfortably take the roots. The best pots for Auriculas are those of the long thumb pattern, and are usually supplied without rims and not glazed. Good drainage is most essential, and the pots can be filled one-third of their depth with clean potsherds, over which is arranged a thin layer of fibrous loam to secure a free outlet for water. Both the pots and the drainage material must be quite clean, and if they have been previously used for Auriculas, a good scrubbing will be needed to remove all traces of the woolly aphis. Having prepared the soil and pots, the repotting may be commenced. All the old drainage is taken away and most of the soil, but I do not agree with the method of shaking all the compost out and washing the roots in a concoction of soft soap and water. Enough soil, however, must be removed so that the tap-root can be examined, and if the end is decayed, it should be cut back to the living tissue and then rubbed over with a little powdered charcoal or lime. In all probability the roots will be partially covered with the woolly aphis, but the amateur need not be alarmed, as it is very questionable whether this pest does any harm. Before disturbing the ball of soil I just go over the roots with methylated spirit or Tobacco powder if this pest is present, and most, if not all, of the aphides are destroyed. The plants are placed in the pots so that the leaves are near the soil, which is made moderately firm, leaving sufficient space for watering purposes.

After-Treatment.—This I shall deal with more fully next month. For the present keep the plants shaded from all strong sunlight till they are re-established. A good watering will be needed after they have been arranged in their growing quarters, and afterwards they must only have enough water to just keep them from drooping.

T. W. BRISCOE.

SCHOOL FLOWER SHOWS IN SPRING.

FOR the last seven or eight years we have had, every spring, a show of bulbs grown in pots at our small school. During three years of this time we were fortunate in having Mr. Charles Hodson as our master, for he did much to develop it, and to him we owe much of our success. Twelve months ago he left to take charge of the large and important boys' school at Paddock, which is now practically part of Huddersfield. Thither he has transplanted our show. On Saturday, March 7, the offset bloomed. I was there to see it, and the result gave me a very great deal of pleasure and satisfaction. I came away feeling more than ever that all such shows are an admirable adjunct to the ordinary curriculum of a school. Children, parents, grandparents, friends, old scholars, educational big-wigs, inspectors, school managers, clergy and teachers filled the room,

for their own sake, which in turn may, I hope, become the foundation of a hobby which for rich and poor alike is surely among those that are the most lasting, pleasure-giving and practicable of all.

The illustration on this page gives one a very good idea of how the schoolroom and desks may be arranged. If the competitive classes of the children can be supplemented by a display from a neighbouring greenhouse, or if some cut flowers can be begged for selling, it will add to the interest. The success of the display naturally depends upon the varieties of bulbs chosen for the children to grow. Tulips are always the difficulty, and I do not recommend these until the children have become familiar with growing Daffodils and Hyacinths. I have also found by experience that either the last Saturday in February or the first one in March are the best dates for the show.

The two main items of expense are the provision of prizes and the purchase of bulbs. We generally at my own school give four prizes, or sometimes five, in each class. As a rule, they are one shilling, ninepence, sixpence and threepence.

A DAFFODIL SHOW IN A SCHOOLROOM.

rubbed shoulders, looked at the flowers, and generally hobnobbed and talked.

Thus partition walls of aloofness and prejudice are broken down, interest is kindled and stimulated, opportunities for home visits by the head teacher and his assistants are given, and a day quite out of the ordinary is forthwith established, which is looked forward to both by teachers and children as one of the red-letter days of the school year. To the above add the *esprit de corps* which all these things undoubtedly fosters, and I think I have made out a case for school shows even without any direct reference to the plants themselves.

The direct benefit in teaching gardening by growing a few Tulips, Hyacinths and Daffodils in pots is very small indeed. Something about the functions of roots and leaves, the necessity for water, the influence of cold and heat, and the importance of a pure atmosphere may be picked up by the sharper children. But for the many, perhaps the most particular good that this participation in the show confers is in the having something to look after and think about in a rather dull time of the year, coupled, perchance, in certain cases with the learning to love flowers

Suppose, then, that there are eight classes, the prize money would come to one pound. Again, each potful, whether it be one Hyacinth, four Daffodils or three Tulips, is sold for a penny, so there is the difference between the cost to the school and the selling price to the children to be made up. By the way, sales should *always* be effected under colour and *never* under name.

I close these notes with a list of what I have found by practical experience to be the best varieties of each to grow, having due regard to price and dissimilarity: Tulips.—Vermilion Brilliant and possibly La Reine. Daffodils.—Golden Spur, obvallaris, princeps, Queen Bess, Sir Watkin and Telamonius plenus. Polyanthus Narcissus.—Dr. Holland, Mont Cenis and Alsace (Poetaz). Hyacinths.—L'Innocence, General de Wet, Marie, Oranje Boven, Schotel, R. Steiger, Grand Maître and Lady Derby—really, I may say any variety that opens well and has a strong stem.

A list of bulbs suitable for growing for a first show with eight classes is here appended: Daffodils (three in a pot, except Queen Bess).—Golden Spur, princeps, Queen Bess (four in a pot) and Sir Watkin.

Polyanthus Narcissus (three in a pot).—Dr. Holland. Hyacinths (one in a pot).—L'Innocence (white), Schotel (pale blue) and General de Wet (pale pink). If only six classes are required, leave out Queen Bess and Sir Watkin. If twelve classes are wanted, add Tulip (three or four in a pot) Vermilion Brilliant; Hyacinths Oranje Boven and Grand Maftre; and Poetaz (three in a pot) Alsace. The most useful-sized pots are 4-inch, 5-inch and 6-inch. JOSEPH JACOB.

[We are pleased to publish Mr. Jacob's article, and hope that it will induce others to hold similar shows. Those who have never seen it cannot realise the vast amount of pleasure that a child obtains from cultivating a few bulbs in pots. It is summed up in those magic words of pride: "I have grown them myself." Mr. Jacob will be glad to give anyone assistance who is contemplating starting a show of this kind.—ED.]

FILMY FERNS FOR A COOL STRUCTURE.

IT is matter for surprise that the Filmy Ferns, even in large establishments, are generally conspicuous by their absence. I can only assign one reason for this, viz., that their merits have not been sufficiently brought before the public, either by vendors or writers. They are invariably found, with true modesty, like a King-designate of old, hiding away among other plants. Having had the privilege of serving my apprenticeship where one stately specimen of the class (*Todea superba*) was grown, I have always had a warm place in my affections for the "Filmies," and have continued to cultivate a few; most visitors who come this way are invited to have a peep at them, and few see them who do not readily appreciate their beauty.

Their culture is very simple, shade and moisture being the two essential conditions. Here we grow the *Todeas* in a small unheated structure at the north side of the fernery, while a *Trichomanes* and several *Hymenophyllums* are grown in a Wardian case in the fernery, where a warm greenhouse temperature is maintained; but any of those noted below can be grown in an unheated structure if they are not subjected to more than a few degrees of frost. The *Todeas* are best grown in pots, but the *Hymenophyllums* do better in pans, and the *Trichomanes* can be grown in either. All of them should have perfect drainage, and they all succeed well in a compost of equal parts of turfy loam, turfy peat, rough Oak or Beech leaf-mould and sand, with a liberal admixture of rough charcoal and sandstone. They may remain undisturbed for several years. As already indicated, they love shade, and from early March to late September they should be heavily shaded. With regard to watering, they should be sprayed once or twice daily during summer and every few days during winter, according to weather conditions and the character and location of the structure. Water must also be supplied liberally at the roots, especially in the case of the *Todeas*.

The following are grown here, and can all be heartily recommended for cool treatment: *Todea superba* and *T. pellucida*—these two require ample room, as under suitable conditions they develop fronds over two feet in length; *Hymenophyllum demissum*, *H. tunbridgense* and *Trichomanes radicans Andrewsii*, an improved variety of the Killarney Fern. CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLETS NOT DOING WELL (*G. R.*).—We fear we cannot say what the cause of the trouble is without seeing the specimens, but we think your best plan would be to make up quite new beds before starting the plants in the frames, keep them thoroughly ventilated, and make sure water never stands about their crowns.

IRIS RETICULATA (*U. S. A.*).—If you permit the plants to mature their season's growth and lift the bulbs any time between the middle of June and the middle of July, no harm will ensue. The larger bulbs will then flower in 1915 quite well. It is important that the bulbs are not sun-dried, that is, spread out in the sun to dry, and equally important that they are not kept too long out of the soil. If you give the bulbs a maximum period of one month's rest, keeping them meantime in a pot of quite dry sand, they will be quite safe. Kept too long in the dry state, a species of dry-rot overtakes the bulbs and they perish in the soil after planting. When replanting, employ a liberal depth of sandy loam and avoid crude manures.

ROSE GARDEN.

BANKSIAN ROSE NOT FLOWERING (*F. S.*).—You must not prune the small twiggy growths; but if the tree is too smothered with big shoots, cut some quite out to their base, so as to allow sun and air to enter freely. If you could train the tree into a sort of bower, we think you would soon obtain blooms in your part of the world. The Dorothy Perkins should have some of its main growths trained horizontally, and if there is a dense mass of growths, cut out some of the very oldest at once. The small shoots springing from the main growths should be cut back to two or three eyes, excepting some which may be stronger than the others. These you can retain from 12 inches to 18 inches in length.

PRUNING A SWEET BRIAR HEDGE (*E. C.*).—It is usual to prune hedges of Sweet Briar after the flowers are over, but, providing you do not mind losing a certain number of flowers, the work may be done at once. Cut as much of the old wood out as possible, and tie the younger branches into position in order to keep the fence of uniform density. Towards the end of the summer go over the hedge again and remove or shorten any branches, where necessary, thus leaving it tidy for the winter. If you require to increase your stock of Violets, leave a sufficient number of runners for your purpose; but if you think that you can procure all the plants you require by dividing the old ones, then remove all the runners at once, for they will only tend to weaken the old plants.

PRUNING ROSE REVE D'OR (*E. L. J., Croydon*).—Yes; our correspondent was right in his advice. Of course, you would not cover your wall so quickly by cutting back the annual growths so hard as recommended on page 154, but you would obtain blooms of a superior quality from the ends of the long growths. There would, doubtless, be some flowerless growths, but if these were pinched in the autumn they would ripen well and flower the next year.

We have seen this old Rose covering lofty house fronts in Devonshire, making a glorious show, and the pruning adopted has generally been carried out with the shears. We planted several plants of this Rose last year quite late, and cut them back hard, with the result that we had fine clusters from the extreme ends of the new growths, and, as you say, with glorious foliage.

THE GREENHOUSE.

INJURY TO PELARGONIUMS (*Zonal*).—The Pelargoniums have apparently been grown in a moist atmosphere with rather a high temperature. This has made the leaves sappy, and immediately the plants suffer, if only for a short time, from dryness at the root, or are stood in a dry atmosphere or in a draught, the leaves lose more water than they can afford, with the consequence that they "burn," as those sent have done. The remedy, of course, lies in checking the rapid growth of the foliage by altering the conditions.

CULTIVATION OF LOTUS PLANTS (*Lady Beaumont*).—Lotus plants should be grown in loamy soil in shallow water in a greenhouse where a tropical temperature can be maintained. The best results are secured when the plants can be grown in a tank, the soil coming to within a few inches of the surface of the water, and a constant supply of fresh water maintained. Fair results may also be obtained by planting the roots in tubs, providing care is taken to give fresh water daily. Use four parts good fibrous loam and one part leaf-mould with silver sand about the roots. The plants resent frequent root disturbance, therefore care must be taken to plant them permanently when they are first put out. Full sun is necessary to success.

FRUIT GARDEN.

CHERRY BLOSSOM STERILE (*J. H.*).—The cause of the flowers not setting, we think, lies in their quality. If you will examine them closely, you will probably find that there is very little pollen on the anthers. If this is not so and the pollen is abundant and strong, there is no reason why the fruit should not set freely if you will take the precaution of distributing the pollen among the flowers on dry, warm days with a rabbit's tail so that it comes in effective contact with the stigma or centre column of the flower. If it turns out that the quality of the flowers is at fault, your best way is to take up the trees and replant them in rather lighter soil (although the Cherry likes a strong soil), adding plenty of drainage, and planting the top roots of the trees practically on a level with the surface soil, mounding up the surface soil to a height of 5 inches. This should be done immediately after the trees shed their leaves.

THE VINE AND ITS AERIAL ROOTS (*L. D.*).—This is a common experience with the Vine, especially with those Vines which are getting old. The primary cause, we think, arises from the fact of the root action being too sluggish and weak to support the crop of foliage and fruit, causing the Vines to throw out these roots (aerial) for further help, the growth of which the moist air of the vinery encourages. Vines are sometimes propagated by these "porcupine fibres," as you call them. All you have to do is to tie a 5-inch flower-pot full of soil at the junction of a shoot from which the roots emanate. This must be done on the first appearance of the roots. At the end of the summer the pot will be full of roots, and the shoot to which they are attached may then be severed from the Vine, and at once becomes a detached entity. The way to prevent their recurrence is to renew the Vine borders in autumn with proper Vine soil.

MISCELLANEOUS.

INJURY FROM CREOSOTE FUMES (*E. L.*).—It is highly probable that the creosote fumes have been the source of the trouble. Could you not take the plants out and heat the house up for a while? Failing this, standing pails of water about in the house may help to absorb the fumes.

TO CLEAR A POND OF ALGÆ (*G. S. C.*).—All that you can do towards clearing your pond of Algæ is to use copper sulphate at the rate of one part to from 750,000 to 1,000,000 parts of water. At this strength it is unlikely to injure the plants round about, neither will it have any serious effect upon the water in the well. The same chemical is used in some countries for clearing reservoirs of drinking water from weeds of the Algæ type. Water Lilies will grow among the weed, but will not smother it; in fact, the weed in the end will probably exercise a more harmful influence upon the Lilies than the Lilies upon the weed.

TOMATOES IN BOXES (*Nemo*).—For single plants a box 1 foot long, 10 inches wide, and 5 inches or 6 inches deep will be large enough. Top-dressings of soil and manure may be added in due course. If two or more plants are grown in a box, the latter should afford accommodation for the plants in due proportion, the box for a single plant being taken as a guide.

NAMES OF PLANTS.—*Bramford*.—*Pyrus spectabilis*.—*Niche*.—1, *Helleborus foetidus*; 2, *Billbergia nutans*.—*Cherry*.—1, *Prunus serrulata*; 2, *Lonicera punicea*.—*C. S. G.*—*Orchis mascula*.—*Quidith, Glos.*—*Daphne pontica*; quite hardy, thrives best in shade.—*H. C.*, *Sleaford*.—*Staphylea pinnata*.—*G. G.*—1, *Prunus Padus* (Bird Cherry); 2, *Albuca fastigiata*; 3, *Arthropodium cirrhatum*.—*Regular Reader*.—The Tulip is an old, unnamed garden variety. It somewhat resembles Rose Dorée.

THE GARDEN.

No. 2217.—VOL. LXXVIII.

MAY 16, 1914.

NOTES OF THE WEEK.

The Chelsea Show.—The Rev. W. Wilks informs us that Her Majesty Queen Alexandra has signified her gracious intention of visiting the Royal Horticultural Society's Great Show at Chelsea on Tuesday next.

Classification of Roses.—We understand that the Council of the National Rose Society have decided to class such Roses as Rayon d'Or, Lyon, Arthur R. Goodwin and Willowmere as Pernetiana Roses.

A Beautiful Gromwell at Wisley.—One of the most charming features in the rock garden at Wisley just now is the magnificent Gromwell shown in the accompanying illustration. Botanically, this is known as *Lithospermum prostratum* Heavenly Blue. The plant depicted on this page covers a space of about four feet by three feet, and is one of the best we have ever seen. It is of dwarf, shrubby character, and appreciates rather sandy soil. Its flowers are rich blue—we had almost said Gentian blue—and are always highly appreciated at this season.

Our Stand at the Chelsea Show. At the great Chelsea Show, to be held next week, our stand will be situated in the Lime Tree Avenue, and we trust that as many of our readers as possible will make a point of calling there. We also call attention to our next issue. This will be a special double number, and will contain a full illustrated report of the show. We hope to have copies on sale at our stand by noon on the Wednesday.

Planning and Planting the Little Garden.—In this issue will be found particulars of a competition for planning and planting the little garden. During recent years there has been a rapidly increasing demand for plans of gardens of small dimensions. Too often the little garden is planted piecemeal, without any thought as to its appearance when finished, and the result then is usually far from satisfactory. That a little garden can be made as pleasing and as much in keeping with the dwelling house as one of larger dimensions, we know quite well, and it is with a view to demonstrating this that the competition has been arranged. Judging from letters that we receive, many of our readers possess considerable talent in planning and planting the little garden, and we hope that this competition will be the means of bringing to light many valuable and interesting suggestions.

Canterbury Bells.—In many places these useful subjects play an important part in the adornment of the flower garden, particularly where an early summer display is wanted. To obtain good results a little extra care should be taken in the preparation of the seed-bed. The seed may be sown from now till the middle of June, pricking out the young plants early to ensure a good sturdy growth.

Planting Bamboos.—This is a suitable time for transplanting these ornamental subjects. The first and most important point is to thoroughly prepare the soil, stirring the ground to a depth of not less than 2½ feet to 3 feet, enriching it with farmyard manure. The propagation is easily

after the flowers are over. Wallflowers, Polyanthuses, Myosotis, Silene, Pansies and Aubrietias may easily be raised from seed, which should be sown without delay.

Viola gracilis.—Although it is nearly a century since this charming Viola was first introduced into this country from Greece, yet it is only of recent years it has received much attention; indeed, it practically dropped out of cultivation for many years. At the present time it is one of the most decorative of garden plants on the rockery, where it has been a mass of flower since early in the year. If used as a carpeting to a bed of white Tulips, such as Pottebakker, the effect is most striking, and worthy of consideration when planning beds for display next spring.

A Pleasing Spring Bed.—A particularly quiet and charming arrangement—and one quite out of the common run—may be made by planting a good type of blue *Scilla campanulata* between white *Polyanthus* Primroses. The green leaves of the Primroses and their milk white blooms below the blue haze of the Bluebells is very beautiful when seen from a little distance, and then in the evening, if we go closer, the combination of scents is delightful, and almost certain to make us stop a few moments to get a whiff or two more of what is to many perhaps a new fragrance.

Paulownia imperialis Flowering at Kew.—Although this Japanese tree frequently perfects its blossoms in the South-West Counties, it rarely does so in the neighbourhood of London, for the inflorescences which are formed in autumn usually fall a prey to winter cold or the frosts of early spring. They have escaped this year, however,

LITHOSPERMUM PROSTRATUM HEAVENLY BLUE IN THE ROYAL HORTICULTURAL SOCIETY'S ROCK GARDEN AT WISLEY.

and a tree at Kew, near the Temperate House, is carrying numerous heads of the large, purplish, Gloxinia-like flowers for which the tree is famous. Not for twenty years, at any rate, has it been known to blossom so well at Kew. For places where it is likely to perfect its flowers annually it is an excellent tree to plant, for not only are its flowers showy, but the leaves also are ornamental. In less favoured gardens it may, however, be used to produce a subtropical effect, for if kept to one stem and cut back to near the ground line in spring each year it forms enormous leaves, often 2 feet across. It must, however, be planted in good rich soil for this purpose.

The Propagation of Spring-Flowering Plants. Most of the plants for spring bedding require to be propagated now. The choicer varieties of *Aubrietia* should be propagated by cuttings as soon as the flowering period is over. These may be struck in boxes of sandy soil if placed in a close pit and protected from strong sun. Double and single *Arabis* may easily be increased by division of the plants

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Forget-me-nots in the Rock Garden.—The Forget-me-nots are a valuable section of our spring-flowering plants, their blue colour making such a pleasing contrast to the yellow of the Narcissi which bloom at the same time in my garden, the Myosotis forming a neat and charming carpet through which the Daffodils push up. Of the several Forget-me-nots now seen in the alpine garden, the form of *M. alpestris* known as *rupicola* (or is it a species?) is very dwarf and attractive; while another of considerable charm and becoming deservedly popular is the variety *Ruth Fischer*, having particularly bright-coloured flowers with a yellow centre. For the bog, *M. cæspitosa*

Disease in Chionodoxas.—I am much interested in the note by Mr. Hadden and your editorial remarks upon it on page 215, issue May 2. The fact that *Ustilago Vaillantii* occurs on *Chionodoxas* was first made known to me by some bulbs being sent me by Mr. Edward Whittall of Smyrna, with a remark to the effect that they had a "smoke-coloured eye." On their flowering, the centre of the flower was seen to be filled with grey fungoid growth, and Mr. Whittall afterwards wrote to inform me that the "smoke-coloured eye" was caused by this fungoid disease. On observing it I pinched off the flower, but the following year the fungus again appeared. In some following seasons the same thing happened, but I never saw any other plants, either of *Chionodoxa* or *Scilla*, affected with this *Ustilago* in my garden. As the disease appeared to be persistent in the bulbs, I lifted and destroyed them, in case they

your readers would recommend any new *Primula* suitable for growing inside in winter which would be free from this danger of rash.—J. D.

Aster Disease.—In your issue of the 4th ult., page 167, there is a corroboration from a Kentish reader, "T. W.," of my advice *re* treating China Asters as hardy annuals; he then arraigns me for advising non-thinning of the seedlings. I do advise it, where necessary, but in the great majority of cases the seed is too scarce to make a thick sowing; also I was more concerned with disease prevention than with general culture, and wittingly used the words "neither transplanted nor thinned," because I have purposely left very thick sowings as an experiment to see if the decrease of stamina so caused would render the plants susceptible to disease, but found it was not so, and in each case the quality of the bloom surpassed my expectations, considering their crowded condition. Moreover,

against the theory that the disease is largely caused by the plants getting leggy in the seed-boxes, it is a well-known practice in many understaffed gardens to sow half-hardy annuals so thinly in the seed-boxes that the pricking off process may be omitted. Under these circumstances the young plants have no chance of becoming leggy, and yet I know from experience that Asters so treated are unreliable, and, apart from this, it would not account for large thriving plants—the picture of health and often actually in bloom—collapsing and dying in an hour or so.—F. M. S., *East Yorks.*

Saxifraga burseriana and its Varieties.—If I should be one of the perpetrators who have used the word "type" in a misleading sense, I beg "E. H. J.'s" (page 215) forgiveness, asking him to put the blunder down to my inexact knowledge of English. I now see I should have spoken of "species" for these, as they occur in Nature. I meant to refer to it in my note (page 179, April 11). I am, however, pleased "E. H. J." referred to the late Mr. Selfe Leonard as having been the first to introduce improved types "from a new locality," for this commendation reflects some of its rays on my mediation. In the spring of 1897 Mr. Selfe Leonard received from me a

large consignment of *S. burseriana*, in reference to which he wrote me in the ensuing spring that by it he had made a most satisfactory purchase, the majority of the plants having proved to be the variety major. Since that time I have, almost annually, supplied plants to England, collected in that same locality, and cannot help thinking that to varieties selected from these consignments the big names now existing have been given. I do not know whether *S. burseriana* is raised from seeds to any extent in England. I had the advantage of accompanying Mr. Selfe Leonard on a pleasant trip in the Tyrol in the summer of 1897, and on his untimely death afterwards I have, in memory of this gentleman's genial personality, kept his catalogue by me ever since. In this catalogue is figured a plant of *S. burseriana* major, the photograph of which I have no doubt was taken from one of those plants supplied to him by me.—E. HEINRICH, *Planegg, Bavaria.*

MYOSOTIS RUTH FISCHER. THIS HAS BRIGHT BLUE FLOWERS WITH YELLOW CENTRES.

Rehsteineri is a delightful subject, producing its brilliant *Eritrichium*-like flower 1½ inches to 2 inches above the soil, and spreading in a close matted carpet over the moist earth.—REGINALD MALBY.

Iris pumila.—The illustration on page 225 of last week's issue shows clearly that the Iris in question is not *I. pumila* but *I. Chamæiris*, for the plant apparently produces a stem of several inches in length. This is *I. Chamæiris* from the South of France and North Italy. The true *I. pumila* has practically no stem, but a perianth tube of 2 inches or 3 inches in length. *I. pumila* is in many localities even more variable in colour than *I. Chamæiris*, which in some districts is all yellow, in others all purple, while in others, again, many colour varieties are found growing together. Unfortunately, the true *I. pumila* is comparatively rare in cultivation.—W. R. DYKES, *Charterhouse, Godalming.*

affected others. The bulbs were those of *Chionodoxa sardensis*. Your advice to remove the affected plants as soon as seen is excellent, and should be followed.—S. ARNOTT, *Dumfries.*

Primulas Causing Rash.—I should like to call the attention of your readers to the danger attending the growing of *Primula obconica* and *P. malacoides*. I have grown these plants in my conservatory for a number of years, and they have been a great source of pleasure to me, as well as being most useful for table decoration. My gardener has worked among them with the greatest freedom for many years, but this year he was attacked most severely with a rash, which caused great suffering and sleeplessness. I had, therefore, much to my regret, to destroy over fifty fine plants. May I suggest to anyone growing these plants that gloves should be worn while handling them? In addition to the above-named Primulas, I have grown *P. kewensis*. I should feel glad if any of

Gentiana acaulis Sporting.—We have in this nursery a bed of *Gentiana acaulis* raised from seed. I notice among this bed one plant which I am sure is of interest to alpine plant growers. There are two flowers on this plant, which has only one head; and one flower is pure blue and the other an absolutely pure white. It is not a case of two seedlings planted together. I wonder if any other readers of *THE GARDEN* have had a similar freak, as it must be.—R. R. H. HAYES, *Alpine Gardens, Keswick*.

Winter Treatment of *Gentiana verna*.—Last year I read in *THE GARDEN* a note from Mr. R. A. Malby advising that *Gentiana verna* should be covered with glass during the winter. I put glass not only over some plants of *G. verna*, but also over some of *G. acaulis* last autumn. The result has been eminently satisfactory, as the covered plants have flowered bountifully this spring, while those in the same bed which received no such attention have not a bloom upon them. I am very grateful to Mr. Malby for the "tip" he gave *THE GARDEN* readers. Most probably he has gone far to solve the difficulty many people have with these capricious plants.—W. A. BILNEY.

Hardiness of *Arabis aubrietioides*.—I observe that some say that *Arabis aubrietioides* is as hardy as the common white *Arabis* or Rock Cress. I must take exception to this, as *A. aubrietioides* is not so hardy, and will not stand some severe winters in which both *A. alpina* and *A. albida* are unharmed. It should, I think, except in the warmer parts of the United Kingdom, have a more sheltered position than need be given the other *Arabises*. It is acceptable to many because of its delicate pink flowers. It is of looser habit than most of the *Aubrietias*, but for the shade of colour I should prefer *Aubrietia Bridesmaid* to *Arabis aubrietioides*. The latter is, however, a freer-growing subject, and looks well over the stones of the rock garden. It is increased by division of old plants or by cuttings or seeds.—S. ARNOTT, *Dumfries, N.B.*

Too-Much-Alike Auriculas.—I have analysed the price-lists of four of the principal specialists of this lovely spring flower, and find enumerated in the show section thirty green-edged, twenty-four grey-edged, twenty-two white-edged and forty selfs, also one hundred and sixty alpines, all deemed worthy to bear names. It is safe to say that not more than 15 per cent. of the above are ever entered for competition. Is it that the remainder are not up to show form, or is it (as in the case of Sweet Peas) a question of too much alike? Will one of the *cognoscenti* whose articles in your valued paper have done so much to popularise this flower, and whose advice has been so valuable to all interested in its culture, favour us with a select list of alpines, limited to those of very distinct coloration and omitting high-priced novelties? I am convinced that such a list would be much appreciated by very many enthusiastic but short-pursed novices such as—TAPLOW.

Two Good Late Daffodils.—For the purposes of this note I exclude the Poeticus varieties, and refer to what are usually termed "Daffodils" by ninety-nine people out of a hundred. Those who wish to have as long a flowering season as possible may be glad to make a note of Amber and Steadfast as two of the very latest to bloom. Both belong to the peerless (2b) section, of which Lady Margaret Boscawen is a well-known example. Steadfast might be a small sister wearing the

same cut and same coloured clothes. Amber has longer and narrower perianth segments, and a much narrower cup or corona, which is of a deep amber shade of yellow, in some years almost an orange. Both varieties are robust growers, and as useful for cutting as in the garden, for they have fairly long stalks. I grow a variety called Lady Jellicoe, which is the counterpart of Amber, except that the corona is of a slightly deeper shade—at least I think it is, but the difference is very small. If anyone grows or knows both of these (Amber and Lady Jellicoe), I would be very much obliged if they would send a short note about them to *THE GARDEN*.—JOSEPH JACOB.

Newly Planted Chionodoxas.—In view of the evidence which appeared upon page 202, I think I owe to the author of the original note upon *Chionodoxa sardensis* an admission that he is correct in stating it as a general rule that this delightful spring bulb flowers better when established than when freshly planted. With reference to the Rev. Joseph Jacob's query, I may say that my experience of this season's bulbs is not an exceptional one. I well remember that the first bulbs I ever planted, viz., about seven or eight years ago, flowered more vigorously than they have ever done since. I attributed this to the fact that they partly exhausted their strength in ripening a large quantity of seed. But as to the colour of *Chionodoxas*, I am adamant. Not all the colourmen in the world shall persuade me that the blue of *Gentiana acaulis*, *G. verna*, *G. bavarica*, *G. septemfida* and others is to be found in the *Chionodoxa*. There are a few plants with which I am acquainted, such as *Tecophylaea cyarocrocus* and *Tillandsia Lindenii*, for example, which possibly possess blue of a similar intensity. But this is not sufficient. The unique value of gentian blue lies in its metallic or mineral quality. You find the same quality in certain butterflies, most notably in a few Malaysian species. You find it in certain minerals, and, lastly, in freshly tempered steel. I have puzzled in vain to discover why the *Gentian* should possess this peculiar quality. Glorious as is the blue of the *Chionodoxa*, the *Anchusa* (Dropmore) and such other pure blue flowers as *Nemophila insignis*, *Cyananthus lobatus*, *Muscari Heavenly Blue* and the *Scillas*, it is merely blue. *Gentian* blue is something more, not merely by reason of greater intensity, but by reason of its heavenly lustre. Why should Mr. Jacob call upon me to furnish a name for the blue of *Chionodoxa*? Is it bluer than the *Scillas*? Let us, rather than have to adopt the clumsy expedient of referring to "Scilla" blue, "*Chionodoxa*" blue and so forth, unite our efforts to crush the monsters who call *Veilchenblau* the "blue Rose"; who talk of the "blue" *Gladiolus*; who, having progressively applied the sacred term "blue" to every conceivable shade of purple, mauve and lilac, will in all human probability proceed next to commit the final desecration of applying it to magenta. Were we once to rescue "blue" from the hands of these fiends and restore it to its pristine significance, there would be no need to invent fresh colour descriptions.—RAYMOND E. NEGUS, *Walton-on-Thames*.

FORTHCOMING EVENTS.

May 19.—Royal Horticultural Society's Spring Show at the Royal Hospital Gardens, Chelsea (three days). Devon County Show (three days).

May 20.—National Tulip Society's Show at Chelsea (two days).

SWEET PEA NOTES.

THE succession of brilliant sunny days of the past weeks has done much to mitigate the dire effects of the miserable weather of the preceding month. Sweet Peas under glass have revelled in the sunshine and the air that could be so freely given them, and, on the whole, the prospects of a better Sweet Pea year are most promising.
